run-down children, but is it not first of all the duty of the sanatoriums to provide for the care of tuberculous patients awaiting hospitalization? Furthermore, since one of the main functions of the tuberculosis sana-

a ratio of 1 52. The ratio of full-time physicians to patients is 1 63 in the state sanatoriums, 1 62 in the county institutions, 1 78 in the municipal sanatoriums, 1 72 in those under city and county control, and 1 45 in the privately owned sanatoriums. By including the part-time medical directors who are regular members of the staff, the ratios in the civilian sanatoriums become 1 62, 1 51, 1 70, 1 60 and 1 32 respectively. The sanatoriums as a group have a ratio of one physician to fifty-eight patients. With the part-time medical directors included, the ratio is 1 49.

Of the tuberculosis sanatoriums, 318 have a full-time medical staff, 120 sanatoriums have one physician on full-time duty, sixty-six have two, forty-four have three, and in eighty-eight institutions there are more than three physicians on full-time employment. Resident pathologists are employed in eleven sanatoriums, and resident roentgenologists in eight.

The table entitled "Medical Staff" is included to show the number of sanatoriums, the average bed capacity, the number of regular staff members, and the number of physicians per institution.

Some of the tuberculosis departments of hospitals have a full-time medical staff, but more commonly the staff physicians share in other hospital duties as well

toriums is segregation, is it consistent, from an epidemiologic point of view, to place nontuberculous children in the same institution in which there are open cases of pulmonary tuberculosis?

MEDICAL STAFF

The quality of medical service depends on the competence of the medical staff. For this reason it is essential that the medical personnel be selected on the basis of training and experience. Especially is it necessary that medical superintendents or directors should be well qualified in the specialty of tuberculosis, for they are responsible for the welfare of the sanatorium patients, for medical policies, and for the supervision and training of the younger members of the staff.

All together, 3,349 physicians are officially connected with the tuberculosis sanatoriums, as shown in table 13. There are 976 physicians on full-time duty, including 273 medical directors. In addition, 178 medical directors serve on a part-time basis, and 2,195 physicians are listed as members of the attending or consulting staff.

The eighteen federal sanatoriums with an average daily census of 3,179 patients have a full-time staff of 101 physicians, a ratio of one physician to thirty-one patients. Eleven Indian sanatoriums included in this group have fourteen physicians and 730 patients,

In the independently operated preventorium the medical service is mainly on a part-time basis, but the preventorium that are part of a sanatorium system may have physicians assigned for part or full-time service.

NONMEDICAL PERSONNEL

According to table 14 which classifies the nonmedical personnel, there is a total of 26,515 employees in the tuberculosis sanatoriums, exclusive of physicians and

Medical Staff

| Control | Number of Sanatoriums | Average Bed Capacity | Regular Staff Members | Number of Physicians per Institution |

dentists. For the care of patients the sanatoriums have a nursing staff of 7,370, exclusive of attendants. Of this number 4,258 are listed as graduates, 538 as student nurses, 140 as affiliates from other hospitals, and

2,436 as practical nurses. The ratio of nurses to patients can be computed for the various classes of sanatoriums by reference to table 14, and the ratio for individual institutions can be ascertained from the state lists of tuberculosis sanatoriums.

Personnel of Civilian Sanatoriums

| Control | Number of Civilian Sanatoriums Employing | | | | | | | | | | | |
|-------------|--|-----------------|------------------|------------------------|-------------------|------------|----------------------|---------------|-------------------------|-----------------|------------------------|--------------|
| | Number of Sanatoriums | Graduate Nurses | Practical Nurses | Laboratory Technicians | X-Ray Technicians | Dietitians | Graduate Pharmacists | Record Clerks | Occupational Therapists | School Teachers | Social Service Workers | Field Nurses |
| State | 65 | 61 | 41 | 50 | 53 | 40 | 7 | 44 | 10 | 34 | 8 | 2 |

| Private | 178 | 161 | 54 | 78 | 78 | 64 | 21 | 77 | 24 | 27 | 15 | 6 |
| Totals | 453 | 425 | 288 | 246 | 245 | 196 | 43 | 240 | 107 | 151 | 59 | 78 |

Trained personnel for other sanatorium departments include 257 dietitians, fifty-four graduate pharmacists, 427 record clerks, 290 x-ray technicians, 342 laboratory technicians, 144 occupational therapists, 269 school teachers, eighty-nine social service workers and 305 field nurses. In their community service many sanatoriums are aided by trained employees of local health units, so that the number of social workers and field nurses given does not represent the total personnel available for field service.

The tabulation that appears above shows the number of civilian sanatoriums that employ trained personnel for various services. This indicates that laboratory technicians are employed in 246 sanatoriums, x-ray technicians in 245, dietitians in 196, graduate pharmacists in forty-three, record clerks in 240 institutions, occupational therapists in 107, school teachers in 151, social service workers in fifty-nine, and field nurses in seventy-eight.

An analysis of the employed personnel in tuberculosis departments of hospitals has not been made because of the difficulty in making proportionate allowances where services overlap. It is apparent, however, that in most of the tuberculosis departments the personnel can be augmented whenever necessary by the transfer of employees from other hospital services.

HEALTH SERVICE FOR EMPLOYEES

The potential danger of transmission of infection is of paramount importance in the tuberculosis institutions both from an economic and a medical point of view. It seems essential, therefore, that the tuberculosis hospitals should institute periodic physical and roentgen examinations, not only to safeguard the health of employees but to guard against the employment of persons unfit for hospital service.

The present survey indicates that the sanatorium field is realizing more and more its responsibility with regard to health maintenance. Three hundred and eighty-five sanatoriums and ninety-three of the principal tuberculosis departments gave information about the health service for employees. Of the sanatoriums, 257 require a physical examination, 100 make a physical examination "when necessary," 218 require a roentgenogram of the chest, 102 make a roentgenogram "if indicated," and 123 include the tuberculin test. In fifty-three the physical examination is held only at the beginning of the service, whereas in 198 sanatoriums the

employees are examined on entrance and at regular intervals thereafter. Thirty-one sanatoriums consider a roentgen study essential before the employees enter on their service, 111 make a roentgen examination periodically, and there were seventy-six sanatoriums that failed to specify the frequency of their examinations.

The replies from ninety-three tuberculosis departments indicate that seventy-one require a physical examination, twelve examine the employees "when necessary," fifty-six require roentgen studies, twenty-four make roentgen studies "if indicated," and thirty-two employ the tuberculin test.

In 193 sanatoriums and forty-seven tuberculosis departments both a roentgen and a physical examination are required, and there are ninety-nine sanatoriums and twenty-seven tuberculosis departments that make a tuberculin test in addition.

The health survey is not always extended to all employees, for there were a number of institutions which reported that only nurses are examined.

According to table 15, a roentgen examination of employees is required in 59 per cent of the federal, 52 per cent of the state, 62 per cent of the county, 54 per cent of the city and 27 per cent of the city-county sanatoriums, and in 28 per cent of the sanatoriums under private control. Furthermore, 78 per cent of the federal, 58 per cent of the state, 65 per cent

Table 15—Health Service for Employees

| Control | Number of Sanatoriums Reporting | Number of Sanatoriums Requiring | | Tuberculin Test | Number of Tuberculosis Departments Reporting | Number of Tuberculosis Departments Requiring | | Tuberculin Test |
|-------------|---------------------------------|---------------------------------|----------------------|-----------------|--|--|----------------------|-----------------|

| Totals | 385 | 257 | 218 | 123 | 93 | 71 | 50 | 32 |

of the county, 59 per cent of the city, 47 per cent of the city-county and 40 per cent of the private sanatoriums require a physical examination. The table lends itself to a similar analysis of the tuberculosis departments.

GENERAL MEDICAL SERVICE

1 *Admission Procedure*—The admission procedure in tuberculosis hospitals and sanatoriums varies considerably except in the federal institutions, where the eligibility of patients and the method of admission are covered in a uniform manner by specific regulations. In other institutions the patients may apply directly or through the attending physician, tuberculosis clinic, health department, social agencies or a central admission bureau and are admitted on a physician's certificate, on the recommendation of special examiners, on x-ray evidence accompanying the application, or following an examination by the sanatorium staff to substantiate the diagnosis of tuberculosis. To simplify the admission procedure, some of the institutions that comprise a sanatorium system have established a central admission bureau to assist in the classification and assignment of patients. In this manner it is possible to expedite transfers between institutions, readjust

waiting lists, prevent the indiscriminate readmission of patients and maintain a closer check on the local tuberculosis problem

Although most institutions have definite rules covering the eligibility of patients, there are individual variations on the basis of race, nationality, age, sex, memberships and affiliations, and financial requirements, and as regards the form, type and stage of disease. There are, for example, ten sanatoriums for Negroes exclusive of separate departments in other institutions. Five sanatoriums accept only women, eleven are exclusively for men, and eleven sanatoriums and the twenty-nine preventoriums admit only children, viz

There are nine sanatoriums that admit patients principally on the basis of membership in fraternal or industrial organizations, and two accept patients only for vocational guidance and rehabilitation. Most of the sanatoriums for pulmonary tuberculosis accept all stages of the disease, although a few attempt to limit their admissions to minimal or early cases. Some institutions were originally established for the treatment of recoverable types of tuberculosis. At first this meant that only minimal cases could be accepted, but now with the improved methods of treatment the "recoverable" classification may include also many patients in the moderately advanced and far advanced stages. In some institutions a quota system may be applied to limit the admissions by districts or on the basis of financial support.

2 General Sanatorium Service—In most of the sanatoriums the routine diagnostic study on admission includes a medical history, physical examination, and laboratory and x-ray studies. There is, however, a great variation in the completeness of these examinations. In some institutions the initial examination includes only a brief reference to the medical history, a physical examination limited mainly to the chest, a

urinalysis, and a sputum examination. In others the staff obtains a detailed history to determine the source of infection, early symptoms, mode of onset, and so on, and carries out a complete general examination as well as a special chest study. Roentgenograms are included, flat films or stereoscopic, also a fluoroscopic examination, qualitative urinalysis, repeated sputum examinations, blood counts, hemoglobin determinations, blood sedimentation, and a Wassermann or Kahn test. In addition, some of the sanatoriums make routine blood chemistry studies and basal metabolic ratings. Two hundred and fourteen sanatoriums hold diagnostic conferences to discuss observations, classify patients, and outline further treatment.

Roentgen examinations are routine on admission in 398 sanatoriums, a urinalysis in 395, blood counts in 253, sputum examinations in 405, blood sedimentation in 177, and a serologic test for syphilis in 195. Physical examinations are repeated within three months in 382 sanatoriums and every three months or over in fifteen, and thirty institutions reexamine patients "when necessary." In 167 sanatoriums the roentgen studies are repeated within three months, and 114 report roentgen examinations at intervals of from three to six months. Temperatures are taken once a day in twenty-two sanatoriums, twice daily in 215, and three times or oftener in 200. In nearly all institutions the temperature is taken by mouth, only twenty report the routine use of rectal temperatures.

Although rest has long been considered the basic treatment in tuberculosis, there is still considerable variation in the application of rest therapy, especially as regards rest periods, visiting hours and graduated exercise. In many institutions the patients remain on strict bed rest until all symptoms have disappeared and the physical condition is shown to be satisfactory by roentgen examination. Some sanatoriums, on the other hand, begin mild forms of exercise much earlier. Many institutions have recently placed increased emphasis on the importance of routine rest therapy and have established definite rest hours both in the morning and in the afternoon. One hundred and fifty-one sanatoriums maintain one rest period daily and 273 require two or more periods of enforced rest.

Visiting hours have been restricted in several sanatoriums to avoid the unnecessary disturbance of patients and interference with the methods of treatment. In 280 sanatoriums visiting is permitted daily, whereas in 135 institutions it is restricted to two or three times a week.

MEDICAL FACILITIES

1 Pneumothorax—The increased use of collapse therapy has been one of the main factors responsible for the great progress made in the tuberculosis field during the last twenty years. Of the various forms of collapse, artificial pneumothorax is by far the most popular and has become indispensable in the operation of a scientific and progressive tuberculosis service. Its sphere of usefulness is not limited to the sanatoriums alone but has extended into the general medical field as well.

A total of 406 sanatoriums and 101 of the principal tuberculosis departments report facilities for pneumothorax. The sanatoriums include seventeen federal institutions and fifty-nine state, 160 county, seventeen municipal, twelve city-county and 141 private sanatoriums. In some institutions, where the pneumothorax apparatus is furnished by the visiting staff, the treatments may be administered at the institution or

in the doctors' offices. The technic of pneumothorax administration varies considerably in the different institutions. In some the procedure is in the nature of a major surgical operation requiring a rigid aseptic technic, whereas in others it involves mainly the use of sterile needles and the usual skin preparation.

Table 16 shows the number of special therapeutic procedures carried out in approximately 400 sanatoriums and 100 of the principal tuberculosis departments. During a twelve months period there were 561,567 pneumothorax treatments administered, 29,678 in the federal institutions, 443,927 in the other public institutions, and 87,962 in the tuberculosis institutions under private control. The departments and the sanatoriums administered relatively the same number of pneumothorax treatments, for there were 450,100 treatments given in the 401 sanatoriums of 59,913 beds and 111,467 in the 101 departments in which the bed capacity was 14,170. A group of institutions reported 16,401 initial pneumothorax treatments and 503,573 refills, indicating an annual ratio of approximately 1:30.

Incidentally, 82 tuberculosis departments and 292 sanatoriums report a total of 2,076 oleothorax treatments.

2 *Surgery*—Apparently the centralization of tuberculosis surgery continues to predominate in the sanatoriums which have established affiliations with surgical centers. The distribution of surgical facilities in the various types of sanatoriums are given in the following table.

Surgical Facilities in Various Types of Sanatoriums

| Control | No. of Sanatoriums | Minor Surgery | Major Surgery | Special Chest Surgery | Surgical Affiliation |
|-------------|--------------------|---------------|---------------|-----------------------|----------------------|
| Federal | 18 | 18 | 15 | 13 | 11 |
| State | 65 | 58 | 21 | 25 | 46 |
| County | 173 | 139 | 51 | 59 | 130 |
| City | 22 | 16 | 11 | 9 | 16 |
| City-county | 15 | 11 | 2 | 5 | 12 |
| Private | 178 | 122 | 33 | 40 | 118 |
| Totals | 471 | 364 | 138 | 152 | 333 |

Reports from approximately 400 sanatoriums and 100 of the principal tuberculosis departments indicate that 2,935 thoracoplasties, 929 pneumolyses and 7,695 phrenic nerve operations were performed during a twelve months period. In checking a group of 122 tuberculosis departments of general and other hospitals it was found that 108 have equipment for minor surgery, ninety-four have facilities for major operative work and eighty-five have facilities for special chest surgery. Thirty-nine departments maintain a surgical affiliation with other hospitals.

Table 16—Special Therapeutic Procedures

torium field. True, a number of sanatoriums are equipped for major operative procedures, but it is nevertheless still the practice in the majority of institutions to transfer the special chest surgery to nearby surgical centers. Even some of the sanatoriums that have surgical facilities find it difficult to supply a competent surgical staff and provide the volume of operative work necessary to maintain technical proficiency.

There has been a tendency in recent years to construct sanatoriums with complete facilities not only for major operative procedures but also for eye, ear, nose and throat, orthopedic and urologic surgery. Whether this trend will influence the practice of tuberculosis surgery remains to be seen. It is certain, however, that the mounting cost of construction will tend to preserve the present system of centralization.

The sanatoriums do not necessarily refer all types of surgery, although there are many that transfer their patients for phrenic nerve operations as well as for thoracoplasties and pneumolyses. Of the 471 sanatoriums included in this report 364 have made arrangements for minor surgery, 138 have equipment for major operations and 152 report facilities for special chest surgery. On the other hand, there are 333 insti-

3 *Dental Service*—There appears to be little uniformity in the supply of dental facilities in the tuberculosis sanatoriums. For the most part, however, the larger sanatoriums, especially governmental institutions, are equipped for dental service in a fairly complete manner. Many have departments containing several complete dental units, dental laboratory facilities and x-ray equipment and are staffed by competent professional and technical personnel.

On the other hand, there are many departments which are equipped with only a dental chair and depend on the visiting dentist to furnish the necessary instruments. Between these extremes there are all types of variation. More than 40 per cent of the sanatoriums do not have a dental department but call local dentists as necessary.

Thirty institutions maintain a full-time dental staff, either regular salaried dentists or dental interns, and in 284 the dental service is on a definite part-time basis.

Complete dental facilities are furnished in the sanatoriums of the Veterans Bureau and the U. S. Public Health Service but are more limited in the sanatoriums of the Indian Administration, where small institutions predominate. Approximately 74 per cent of the state

sanatoriums report dental departments, 66 per cent of the county sanatoriums, 59 per cent of the municipal sanatoriums, 60 per cent of the city-county sanatoriums and 41 per cent of the private institutions

According to the following tabulation there are special dental facilities in sixteen federal sanatoriums, 73 private institutions and 184 other civilian sanatoriums

Special Dental Facilities

| Control | Number of Sanatoriums | Dental Departments | Sanatoriums Employing Dentists | |
|-------------|-----------------------|--------------------|--------------------------------|-----------|
| | | | Full Time | Part Time |
| Federal | 18 | 16 | 7 | 0 |
| State | 6 | 48 | 8 | 47 |
| County | 173 | 114 | 6 | 116 |
| City | 22 | 13 | 4 | 11 |
| City-county | 15 | 0 | 1 | 0 |
| Private | 178 | 73 | 4 | 92 |
| Totals | 471 | 273 | 30 | 284 |

4 *X-Ray Facilities*—The present survey indicates that 77 per cent of the sanatoriums have roentgenographic equipment, 78 per cent offer fluoroscopic facilities, 67 per cent have stereoscopic equipment, and 22 per cent of the institutions refer part or all of their x-ray work to other hospitals. The following tabulation shows the distribution of x-ray facilities in the sanatorium field

X-Ray Facilities in Sanatoriums

| Control | Number of Sanatoriums | X Ray Equipment | Fluoroscopic Equipment | Stereoscopic Equipment | X Ray Work Referred |
|-------------|-----------------------|-----------------|------------------------|------------------------|---------------------|
| Federal | 18 | 18 | 17 | 17 | 1 |
| State | 6 | 59 | 59 | 51 | 3 |
| County | 173 | 144 | 142 | 132 | 35 |
| City | 22 | 18 | 17 | 15 | 5 |
| City-county | 15 | 10 | 11 | 9 | 5 |
| Private | 178 | 115 | 122 | 92 | 50 |
| Totals | 471 | 304 | 308 | 316 | 105 |

The extent to which these facilities are used is illustrated by the number and frequency of roentgen examinations. Four hundred and thirty-two sanatoriums reported 62,873 patients admitted, 459,316 roentgen examinations and 356,917 fluoroscopic studies during a twelve months period. Consequently, the yearly average is approximately seven roentgen examinations and five and one-half fluoroscopic examinations per patient. As shown in the accompanying table, these averages are nearly the same for all classes of sanatoriums except the federal group, in which the fluoroscopic examinations average slightly more than two per patient

Use of X-Ray Facilities

| Control | Number of Sanatoriums Reporting | Number of Patients Admitted | Number of Roentgen Examinations | Number of Fluoroscopic Examinations |
|-------------|---------------------------------|-----------------------------|---------------------------------|-------------------------------------|
| Federal | 17 | 4,384 | 28,134 | 9,070 |
| State | 59 | 18,434 | 121,654 | 87,416 |
| County | 169 | 18,988 | 105,864 | 129,102 |
| City | 21 | 8,108 | 64,057 | 43,801 |
| City-county | 14 | 2,779 | 17,002 | 21,546 |
| Private | 162 | 10,090 | 62,090 | 65,892 |
| Totals | 432 | 62,873 | 459,316 | 356,917 |

Eighty-four per cent of the sanatoriums require a roentgen examination on admission, 35 per cent repeat the examination within three months, 24 per cent repeat it in from three to six months, and in 27 per cent of the institutions the roentgen study is repeated when

necessary. The frequency of roentgen examination is shown in the following tabulation

Technical personnel is employed in the x-ray departments of thirteen federal and 245 civilian sanatoriums. There are technicians in fifty-three state, ninety-five county, eleven municipal, eight city and county sanatoriums and seventy-eight sanatoriums under private management

As regards professional supervision over the x-ray departments, there is considerable variation. Only eight sanatoriums have resident roentgenologists. In 220 the medical director maintains supervision, and in

Frequency of Roentgen Examination

| Sanatoriums | Required on Admission | Roentgen Examination Repeated | | |
|-------------|-----------------------|-------------------------------|---------------------|----------------|
| | | Within Three Months | Three to Six Months | When Necessary |
| Federal | 17 | 5 | 8 | 2 |
| State | 57 | 17 | 20 | 22 |
| County | 159 | 72 | 41 | 41 |
| City | 20 | 5 | 5 | 7 |

| Totals | 395 | 167 | 114 | 128 |

144 the medical staff as a whole is responsible for the interpretations. Eighty-seven sanatoriums report the service of a consulting roentgenologist

5 *Laboratory Service*—Although 364 tuberculosis sanatoriums have clinical laboratory facilities, there are relatively few that offer a complete service. Many find it advantageous to refer sputum examinations, bacteriologic studies and serologic studies to the public health laboratories or other departments. In fact, 375 sanatoriums have indicated that part or all of their laboratory work is referred to outside laboratories

Table 17 shows the laboratory facilities available in the tuberculosis sanatoriums. There is equipment for urinalysis in 378 institutions, for blood counts in 349,

Routine Laboratory Tests

| Control | Number of Sanatoriums | Routine Examinations | | | | Blood Sedimentation |
|-------------|-----------------------|----------------------|--------------|---------------------|-----------|---------------------|
| | | Urinalysis | Blood Counts | Sputum Examinations | Serologic | |
| Federal | 18 | 18 | 13 | 17 | 10 | 9 |
| State | 6 | 59 | 39 | 57 | 32 | 38 |
| County | 173 | 154 | 94 | 159 | 89 | 99 |
| City | 22 | 19 | 11 | 20 | 14 | 5 |
| City-county | 15 | 14 | 6 | 14 | 8 | 5 |
| Private | 178 | 131 | 92 | 188 | 43 | 50 |
| Totals | 471 | 395 | 255 | 405 | 195 | 177 |

for sputum examinations in 346, and for blood sedimentation tests in 278. Blood chemistry examinations can be carried out in 169, bacteriologic studies in 209, and basal metabolic ratings in 133. Seventy sanatoriums have facilities for tissue pathology. In eighty-nine institutions there is equipment for serologic tests, and 129 sanatoriums have laboratory animals for bacteriologic studies or research

In a number of sanatoriums there are certain laboratory tests which are considered sufficiently important to be classed as routine procedures. The table entitled "Routine Laboratory Tests" shows the number of institutions in which various laboratory tests are performed as a routine on admission. A urinalysis is routine in 395 sanatoriums, blood counts in 255, sputum examinations in 405, serologic studies in 195, and a blood sedimentation test in 177

Two hundred and seventy-eight sanatoriums report on the amount of laboratory work carried out during a period of twelve months. They admitted 56,033 patients and performed 1,523,953 laboratory examinations, a ratio of 27 examinations per patient. As shown in the next tabulation, the ratio of laboratory examinations to patients admitted is 36 1 in the federal

Ratio of Laboratory Examinations to Patients

| Control | Sanatoriums Reporting | Patients Admitted | Laboratory Examinations | Examinations per Patient |
|-------------|-----------------------|-------------------|-------------------------|--------------------------|
| Federal | 11 | 3,289 | 118,883 | 36 |
| State | 51 | 17,227 | 413,106 | 24 |
| County | 112 | 10,800 | 439,562 | 26 |
| City | 13 | 7,334 | 316,283 | 43 |
| City-county | 11 | 2,210 | 30,100 | 13 |
| Private | 80 | 9,104 | 205,004 | 23 |
| Totals | 278 | 56,033 | 1,523,953 | 27 |

sanatoriums, 24 1 in the state institutions, 26 1 in the county group, 43 1 in the municipally owned sanatoriums, 13 1 in the city-county institutions, and 23 1 in the sanatoriums under private control.

Professional supervision is lacking in most of the laboratory departments, except as it is furnished by the regular medical staff. Only eleven sanatoriums employ

greater, however, for there are many institutions that make no effort whatever to obtain permission for necropsy work. On the other hand, some of the more progressive sanatoriums exceed by far the minimum of 15 per cent that is required in institutions approved by the American Medical Association for educational residencies in tuberculosis.

In the tabulation are shown the number of sanatoriums that have necropsy facilities, the number of deaths and necropsies, and the percentage of necropsies in the various sanatorium classifications.

7 Heliotherapy—Facilities for heliotherapy are quite uniformly present in the sanatorium group. Most of the institutions have made convenient arrangements for sun therapy on porches, on roof solariums or in sun pens. As regards artificial heliotherapy, there is a considerable variation in equipment. Many of the larger sanatoriums, especially those which also conduct a preventorium service, have large and well equipped heliotherapy departments for treatment *en masse*. In others, portable lamps may suffice.

It appears that in the use of heliotherapy the tuberculosis institutions adhere fairly closely to the methods and indications now generally accepted. A few, however, employ heliotherapy as a routine procedure for practically all patients regardless of the type, stage or

Table 17—Laboratory Facilities in Tuberculosis Sanatoriums

resident pathologists, but consultants are available in eighty-five. Thirteen federal and 246 civilian sanatoriums have technical personnel for the laboratory department. Technicians are employed in fifty state, 100 county, eleven municipal, seven city and county, and seventy-eight private sanatoriums.

6 Necropsy Service—Necropsy performance in hospitals has come to be considered an indication of the scientific attitude of the medical staff. From an educational point of view the necropsy is indispensable. It serves to provide a sound foundation on which to build clinical knowledge and by correlation affords a better understanding of the various clinical manifestations of tuberculosis. Especially the younger members of the staff who are lacking in experience will benefit from repeated necropsies even though a certain uniformity of observations may occur. No postmortem examination, however routine in character, is devoid of educational value.

Of the 471 tuberculosis sanatoriums, 124 have facilities for necropsy work. During the annual period considered in this report there were 10,923 deaths reported and 1,869 necropsies, indicating an average necropsy rate of 17 per cent. The incidence of necropsy performance is relatively low in some of the sanatorium groups. In the federal sanatoriums the average necropsy rate is 25 per cent, in the state sanatoriums 11 per cent, in the county group 15 per cent, in the city institutions 37 per cent, in the city and county sanatoriums 10 per cent, and in those operated under private control 9 per cent. Individual variations are still

activity of the disease. Of the 602 institutions that replied to the questionnaire, 440 reported facilities for artificial heliotherapy and a total of 1,589,720 treatments, 1,114,709 for adults, 320,704 for children and 154,307 not classified.

Necropsies

| Control | Number of Sanatoriums | Necropsy Facilities | Deaths Reported | Necropsies Performed | Necropsy Percentage |

| Totals* | 471 | 124 | 10,923 | 1,869 | 17 |

EDUCATIONAL ACTIVITIES IN TUBERCULOSIS INSTITUTIONS

The tuberculosis hospitals and sanatoriums have an important function to perform in the training of physicians, nurses and other personnel for institutional and community needs. At the same time the educational function helps to raise the standards of medical service throughout the tuberculosis field. Thus benefits will accrue to individual patients and to the communities at large.

1 Training of Physicians—As tuberculosis is not a limited specialty but one in which nearly every practitioner participates, it is important that all physicians receive a thorough basic training in tuberculosis.

Undergraduate instruction in tuberculosis is generally considered a responsibility of the medical schools, but the sanatoriums can be of service by contributing clinical and necropsy material for teaching purposes. Similarly, the training of interns is not a function of the sanatorium, since the fifth year in medicine should afford a general training in medicine, surgery, obstetrics and the specialties. Nevertheless sanatoriums can be

* Approved also for Interns

of interns. Incidentally, training opportunities in tuberculosis are offered by 159 approved intern hospitals that report the admission of tuberculous patients for temporary or continued treatment.

The tuberculosis hospitals and sanatoriums do have a definite responsibility, however, for postgraduate training in tuberculosis. This applies to short courses for general practitioners, to educational residencies in tuberculosis, and to advanced postgraduate courses.

Perhaps even more important than the training of undergraduates is the establishment of educational residencies in the tuberculosis institutions. A resident in tuberculosis is a physician who has completed his general internship and is continuing for a period of at least twelve months in a sanatorium or tuberculosis department in order to gain supervised experience in the specialty of tuberculosis. During his term of service, the resident should broaden his general knowledge of tuberculosis. He should learn diagnostic methods, the technic of therapeutic procedures and the routine management of a sanatorium service, including the details of rest treatment, the methods of graduated exercise and the management of ambulatory patients.

The diagnostic training involves accurate history taking, careful and systematic examinations, a correlation of physical observations with roentgen and fluoroscopic studies, and the exercise of medical judgment in diagnosis and subsequent therapy. Necropsy performance plays an important part in the diagnostic service, in that it correlates the anatomic and the clinical manifestations of tuberculosis.

Technical training is an essential part of the educational program. The resident should have an opportunity to study the various forms of collapse therapy and should become proficient in the technic of artificial pneumothorax, both initial administration and refills.

Ninety-three sanatoriums and forty-four tuberculosis departments report an educational service for resident physicians. There are twenty-five state, thirty-eight county, seven city, four city-county and nineteen private sanatoriums in this group. The list of the sanatoriums and hospitals approved by the American Medical Association for the training of resident physicians in tuberculosis includes fifteen hospitals (marked by an asterisk) that are also approved for interns.

While the present survey indicates that the training of undergraduates and residents is the most important educational function of the tuberculosis institutions, there are other tendencies coming into prominence which deserve recognition. With increasing frequency the sanatoriums are establishing short courses for the local medical profession, usually of only a few days' duration but of sufficient length to demonstrate the methods of sanatorium routine, diagnostic procedures and therapy. These meetings also serve to develop the interest of the medical profession in the sanatorium work and to give individual physicians a better understanding of the factors involved in the control of tuberculosis.

Similarly, many of the leading tuberculosis sanatoriums have established a close cooperation with the local county medical society, periodically assuming the responsibility for the program of the society meetings. In this way the sanatoriums acquaint the organized medical profession with the aims and functions of the institution and, through a presentation of interesting cases and roentgenograms, are able to demonstrate the accomplishments of a sanatorium service. It is hoped

of assistance in establishing affiliate services in tuberculosis, which adds considerably to the interns' training in medicine.

The replies to the questionnaire indicate that there are thirteen state, eighteen county, seven city, four city-county and ten private sanatoriums which provide facilities for the training of medical students. Twelve state, thirty county, six city, three city-county and twelve private sanatoriums participate in the training

that both the establishment of short courses and the cooperation with local medical societies will continue to develop as a means of general postgraduate training.

There are at present sixty-seven sanatoriums offering postgraduate training of some form. These include two federal, thirteen state, thirty-three county, four city, three city-county and twelve private institutions. The duration of the course is reported as two weeks or less in nine sanatoriums, from two to four weeks in four, and over four weeks in nineteen institutions. Thirty-five did not state the length of training. Two sanatoriums, the New York State Hospital, Ray Brook, and the Trudeau Sanatorium, Trudeau, N. Y., have been approved by the American Medical Association for postgraduate training in tuberculosis. The Trudeau School of Tuberculosis, established in 1916, has rendered noteworthy educational service to physicians engaged in sanatorium work and to other postgraduate students. The course, offered annually, is of from four to six weeks' duration and may be combined with additional study in Saranac Lake or in the chest service of Bellevue Hospital, New York City.

2 Training of Nurses in Tuberculosis—This report does not deal with the needs of nursing education, nor is it concerned with the actual methods of training, but aims chiefly to enumerate the educational opportunities for nurses in the tuberculosis field.

The training schools in tuberculosis institutions may offer (1) combined courses leading to state registration, (2) affiliate courses for nurses from other hospitals, (3) postgraduate training for graduates, (4) courses for practical nurses, and (5) short courses for attendants employed as nursing aids.

Eighteen sanatoriums have established nurses' training schools, the courses varying in length from one to three years.

Thirty-one sanatoriums report affiliate courses for nurses from other hospitals.

Aside from the sanatoriums there are 740 hospitals with tuberculosis departments of varying size. Nursing schools are conducted in 268 of these hospitals.

including the institutions listed in the accompanying tabulation, which represent some of the principal tuberculosis departments

3 Training of Patients—As long as the tuberculosis institutions continue the hospitalization of nontuberculous children, there will be need for general educational activities comparable to those of the public schools. Naturally, certain limitations will be imposed in accordance with the physical condition of the child, but the objectives of training will remain the same as when the child is at home

Schools for children are maintained in the preventoriums and in 159 tuberculosis sanatoriums. The teaching may be limited to certain grades or may extend through high school. In some institutions the teaching staff is employed privately, in others, by the local department of education. According to reports, there are schools for children in five federal, thirty-two state, eighty-one county, nine municipal and seven city-county sanatoriums, and in twenty-five sanatoriums under private management.

Of even greater importance is the educational service for adults including rehabilitation. The sanatoriums necessarily retain a certain responsibility in the postsanatorium management of patients, from both an economic and a medical point of view. Perhaps only a fourth of the patients discharged are able to return to a normal life, many are permanently incapacitated, and others, although able to work, must limit their activities for many years.

Economically, it is of advantage to reeducate the latter group to a life of economic independence. First of all, these patients must be taught to respect the limits of their physical tolerance, secondly, they must be instructed in occupations that will not tax them beyond their endurance, and, thirdly, they must be assisted financially, if necessary, to live a normal life and avoid a reactivation of the disease. Efforts made to eliminate the need of further hospitalization are well worth while when one considers the cost of prolonged sanatorium care.

While many institutions favor the employment of graduated exercise to insure a complete physical recovery, there are others which lack the necessary housing facilities and funds to carry out such a plan. In some, the pressure of a waiting list may prevent hospitalization after the stage of "quiescence" has been reached, and in others, in which definite limitations have been placed on the hospital service, the patients may be discharged even earlier.

Two hundred and forty-one sanatoriums reported on the use of graduated exercise. Two required half an hour of exercise before discharge, nineteen one hour, fifty-four two hours, eighty-six from three to six hours, and nine from six to eight hours. Eight sanatoriums expressed their exercise requirements in terms of from one to three months, and three required exercise over a period of from four to six months. In eleven sanatoriums daily walks up to three miles were required, while in seven the exercise was extended from three to eight miles. Thirty-nine other sanatoriums that indicated the use of graduated exercise failed to state the amount.

The exercise program is combined with educational activities in many institutions. There are forty-five sanatoriums conducting schools for adults, 141 offer various forms of occupational therapy, and fifty-three have industrial rehabilitation courses. The extent to which these facilities are provided by the various

classes of sanatoriums is shown in the accompanying tabulation.

Two sanatoriums have been established primarily for rehabilitation, and there are others which combine a

Educational Facilities for Patients

| Totals | 45 | 141 | 53 |

convalescent colony with the regular sanatorium service. On the whole, however, there are relatively few sanatoriums offering vocational training—far too few to cope successfully with the problem of postsanatorium care. The sanatoriums in the accompanying list, which report facilities for industrial rehabilitation, may differ widely in their methods and scope of training.

| Oak Sanatorium | Pewaukee Wis. |
| Wisconsin State Sanatorium | Stevens Wis. |
| Mulriddle Sanatorium | Wauwatosa Wis. |
| Wyoming Tuberculosis Sanatorium | Basin Wyo. |

This list indicates that some effort is being made toward vocational rehabilitation in nineteen states, although in some only one or a few sanatoriums participate. Five of these states report an organized rehabilitation service under the direction of the state bureau of vocational education or corresponding agency. Reports from departments of health indicate that in

eight other states vocational guidance is being attempted on a smaller scale by departments of education, local tuberculosis associations, and other organizations.

In a well balanced sanatorium service there must be proper emphasis on prevention, therapy and rehabilitation. Apparently the latter has failed to keep step with the other phases of tuberculosis control.

Another feature of the educational service in tuberculosis sanatoriums is the personal instruction given

employed in seventy-eight civilian sanatoriums, and social service workers in fifty-nine. Their work is supplemented, however, in various localities by the field activities of the departments of health.

MEDICAL RESEARCH

Medical research is a commendable feature of the sanatorium service. It stimulates educational activities, develops new methods of diagnosis and therapy, aids

in maintaining high standards of medical service and, in general, contributes toward the progress of medicine. In the tuberculosis sanatoriums, research takes the form of clinical investigative work or experimental laboratory studies allied to, or independent of, the clinical activities. Only a few institutions have special departments and personnel for research, but in some of the sanatoriums the regular medical staff undertakes research problems of a clinical nature. Research activities are reported in the forty-nine sanatoriums listed in the accompanying tabulation, of which three are federal, nine state, fifteen county, four city institutions, and eighteen privately owned. In this connection it should be mentioned that the Committee on Medical Research of the National Tuberculosis Association, through annual financial grants, helps to extend and coordinate research in tuberculosis.

MEDICAL LIBRARY FACILITIES

The need of medical library facilities in the tuberculosis institutions is generally recognized. The medical staff, in order to function efficiently, must have ready access to text and reference books on tuberculosis as well as on other specialties of medicine and surgery. It is perhaps of even greater importance that medical journals be available, since the new developments in medicine are usually recorded in medical periodicals long before they appear in book form. A medical library is particularly essential in institutions undertaking the training of young physicians and has been made a requirement for residency approval in tuberculosis. Many tuberculosis institutions make provision in the annual budget for the purchase of books and medical journals. Others, however, depend largely on the private collections of books and journals supplied by the superintendent and other members of the staff. Medical libraries have been established in fifteen federal, forty-four state, seventy-five county, ten municipal, five city-county and sixty-four private sanatoriums.

RECORDS

On the whole, the tuberculosis institutions observe closely the general principles involved in the preparation of administrative, statistical and clinical records, but there are many variations in the methods and forms employed and in the completeness of the data recorded.

participates in educational courses for the public at large. One should also consider the educational service of the sanatorium field nurse and the social service worker. When properly organized under medical supervision, the field service becomes a distinct asset to an institution and the community. Field nurses are

An analysis of the reports of the tuberculosis sanatoriums, as shown in table 18, indicates that 387 institutions have record departments, 250 employ special record personnel, and 325 prepare periodic administrative and statistical reports. The clinical records include a medical history in 409 sanatoriums, a social history in 360, a record of the physical examination in 415, reexamination data in 408, progress notes in 390, laboratory reports in 410, x-ray reports in 402, and a pneumothorax record in 385. Heliotherapy records are included in 300 sanatoriums, exercise charts in 256, operative reports in 322, weight charts in 405, nurses' notes in 383, and temperature and pulse charts in 433.

From the inspection reports it was ascertained that the clinical records are fairly complete in 370 institutions, definitely incomplete in fifty-seven, and entirely lacking in forty-four except for nurses' notes and temperature and pulse charts. The present survey indicates that in approximately one fifth of the sanatoriums the clinical and statistical records are inadequate and in many instances entirely lacking.

The lack of uniformity in records is partly due to the fact that many institutions do not have standard record forms but use charts that have been prepared or modified to suit individual needs. In the future, the new and complete record forms devised by the Committee on Record Standardization of the American Sanatorium Association will serve to establish uniform clinical records and comparable statistical data.

There is still some confusion in the methods of classification of patients, although the majority of institutions follow the system advocated by the National Tuberculosis Association and the American Sanatorium Association. In some sanatoriums the statistical data are difficult to interpret because both adults and children are classified together according to types of disease. Since both adults and children are subject to the same forms and types of tuberculosis, there should be little difficulty in classifying them separately, somewhat in the following manner:

| Diagnosis | Adults | Children | Total |
|------------------------|--------|----------|-------|
| Pulmonary tuberculosis | | | |
| Minimal | | | |
| Moderately advanced | | | |
| Far advanced | | | |
| Childhood tuberculosis | | | |
| Other forms | | | |
| Miliary | | | |

COST OF TUBERCULOSIS HOSPITALIZATION

1 *Valuation of Tuberculosis Institutions*—The replacement value of buildings, equipment and land is shown in table 19. In all, 501 tuberculosis institutions representing 71,260 beds, or 74.8 per cent of the total capacity, reported a valuation of \$241,984,951.41. This would indicate that the sanatoriums, tuberculosis departments and preventoriums in the United States represent a sum of approximately \$328,937,777.36. The sanatoriums alone listed \$200,950,434.61 as the value of 60,258 beds, an average of \$3,334.83 per bed. By adding the cost of 4,739 additional beds the total estimated cost is \$216,754,217.67, a sum similar to the 1931 estimate of the National Tuberculosis Association. The data from the tuberculosis departments were not complete because many of the hospitals had difficulty in separating their financial reports by services. However, \$40,000,751.80 was reported as the value of 10,487 beds, or \$3,814.31 per bed. On this basis it is

estimated that the 28,534 beds in the tuberculosis departments have a value of \$108,837,730.69. Twelve preventoriums with a capacity of 515 beds indicated a cost of \$1,033,765 or \$2,007 per bed. Accordingly, the sum of \$3,345,829 represents the valuation of the twenty-nine preventoriums that are operated as independent institutions.

An analysis was made of the sanatorium group to illustrate replacement costs on the basis of size and according to institutional control. This shows that the sanatoriums of less than twenty-five beds average \$1,988 per bed, those of 25 to 49 beds \$2,298, the institutions of from fifty to ninety-nine beds average \$2,745, and the sanatoriums of 100 beds or over represent a valuation of \$3,498 per bed.

The Veterans hospitals operated principally for the treatment of tuberculosis average approximately \$4,000 per bed. The sanatoriums of the Indian Administration average \$2,331, the state and local public sanatoriums are valued at \$3,423 per bed, and the sanatoriums under private control represent a cost of \$3,070 per bed. Some of the sanatoriums built within the last few years show a relatively high cost of construction, averaging around \$10,000 per bed. The highest cost, \$13,043 per bed, was reported by a non-federal public sanatorium.

2 *Annual Maintenance Cost*—Tuberculosis as an economic problem is of major significance, for the cost of tuberculosis hospitalization in the United States exceeds seventy million dollars a year. Five hundred and eight tuberculosis institutions, representing 73,089 beds, or 76.7 per cent of the total capacity, reported an annual maintenance cost of \$55,234,882.25 exclusive of capital additions. On the basis of bed capacity, therefore, the maintenance cost would equal approximately \$75,906,582.41 a year. In 410 sanatoriums with a capacity of 60,701 beds the annual maintenance cost was \$42,822,213.06. This would indicate an expenditure of \$45,852,869.22 for the entire group. Similarly it is estimated that the tuberculosis departments expend \$29,311,492.05 annually and the preventoriums \$742,221.14.

By computing the annual maintenance on the basis of the average daily per capita costs, results are obtained that substantiate these figures. Five hundred and ninety-two institutions reported a daily average of 69,042 patients, or 25,193,760 treatment days. In 563 other tuberculosis hospitals a day's census of patients was 12,910, which on an annual basis would equal 4,712,150 hospital days. Accordingly, at the average rate of \$2.44 per patient daily, the cost of 29,905,910 treatment days amounts to \$72,970,420.40. Furthermore, the same 1,155 institutions had 81,652 patients present on the day of reporting, and this number considered as a daily average would represent 29,802,980 treatment days and an annual maintenance cost of \$72,719,271.20.

Operating expenditures exclusive of capital additions are presented by states in table 21.

3 *Daily Per Capita Costs*—Reports from 410 sanatoriums, eighty-nine tuberculosis departments and fifteen preventoriums show that the tuberculosis institutions operate on an average daily per capita cost of \$2.44. The sanatoriums average \$2.37 daily, the tuberculosis departments \$2.95, and the preventoriums \$1.39. Federal hospitals for the treatment of tuberculosis have an average daily per capita cost of \$3.20. In this group the Veterans Bureau hospitals average \$3.98, the hospitals of the Indian Administration

approximately \$235, and the other federal hospitals \$366. The state and local public institutions operate on an average daily per capita cost of \$211, and the private institutions average \$296 a day.

Considering the sanatoriums as a group, it was found that the lowest daily per capita cost was \$0.50, the first quartile \$1.73, the mean \$2.20, the third quartile \$2.73, and the highest cost \$6.74. The federal sanatoriums average \$2.75 per patient daily, the state sanatoriums \$2.01, the county \$2.10, the city \$2.04, those under city and county control \$1.74, and the private sanatoriums \$2.94.

The tuberculosis departments, which frequently share in the maintenance of a complete hospital service,

from the federal government, 170 receive state funds, 294 county funds, 105 city support, twenty-four receive income from fraternal organizations, eight from industrial agencies, fifty-two from endowments, 104 from gifts, and 254 are supported in part or entirely by pay patients. Approximately 157 institutions have two sources of income, and 105 obtain their financial support from at least three different sources.

In the sanatorium group there are eighteen institutions maintained by the federal government and five civilian sanatoriums that receive federal aid. The states maintain sixty-five sanatoriums and contribute to the support of fifty-five county, three city, one city and county, and twenty-one private sanatoriums. The

reflect a higher per capita cost. The lowest reported was \$0.51, the mean \$2.76, the highest daily per capita cost \$8.96, and the average \$2.95. Table 22 shows the low, mean, high, and average daily per capita costs of the sanatoriums and tuberculosis departments, the average of the preventoriums, and the average cost for all institutions.

4 *Sources of Income*—In considering the cost of tuberculosis hospitalization it is of interest to analyze the sources of income of the various institutions and to determine the number of patients who paid for part or all of their hospital care. The analysis shown in table 23 is based on information from all the sanatoriums and the preventoriums and from 101 of the principal tuberculosis departments, in all 601 institutions. Forty-seven obtain part or all of their income

counties operate 173 sanatoriums and help to maintain seventy-four others, including fourteen state sanatoriums, one city, fifteen city and county, and forty-four under private control. City funds maintain twenty-two municipal sanatoriums and aid in the maintenance of five state, seven county, fifteen city and county, and twenty-one private sanatoriums. Endowments and gifts aid mainly the private sanatoriums, although a few state and county institutions receive aid from these sources. Eight sanatoriums are maintained by fraternal organizations, which also contribute to the support of sixteen others, and there are six sanatoriums receiving income from industrial agencies. Patients contribute toward the maintenance of nineteen state, fifty-two county, two municipal, four city and county, and 149 sanatoriums under private manage-

ment One private sanatorium receives aid from the federal government, twenty-one state funds, forty-four county support, twenty-one city support, seventeen are aided by fraternal organizations, five by industrial agencies, and thirty-nine receive income from endowments, sixty-six from gifts, and 149 from patients. By reference to table 23, similar analyses can be made of the tuberculosis departments and the preventoriums. Practically all the preventoriums operated under private management receive part or all of their income from gifts, which include private donations, public subscriptions, income from seal sales, and funds obtained through the activities of women's auxiliaries, Junior

GROUP CLASSIFICATIONS

1 *Federal Tuberculosis Departments and Sanatoriums*—The federal hospitals, although listed under one classification, constitute separate homogeneous groups serving a restricted population. Each group is under a single administration except in the case of the Indian hospitals, the general management of which is a function of the U S Department of the Interior and the medical supervision a responsibility of the U S Public Health Service.

In most of the federal services the tuberculosis problem remains fairly constant because of the continual replacement of personnel eligible for hospitaliza-

League members, antituberculosis associations, the American Legion, community chest organizations, and other local agencies.

Table 24 reveals the paying status of patients. Data were obtained from 290 tax supported and 130 private institutions, representing a total of 81,583 patients, or 67 per cent of the admissions reported by all sanatoriums, tuberculosis departments and preventoriums. The tabulations indicate that 84.4 per cent of the patients receive free treatment, 9.2 per cent pay in part, and 6.4 per cent pay full rates. Of the 70,078 patients considered in the tax supported institutions, 63,856 received free care, 4,678 were part pay, and 1,544 full pay. The private institutions reported on the paying status of 11,505 patients. Of these, 4,964 received free care, 2,863 were part pay, and 3,678 paid full rates.

tion, but in the Veterans Bureau the problem should decrease year by year and be self limited unless other classes of beneficiaries are added in the future.

In presenting a statistical analysis of the tuberculosis service in federal hospitals, it should be mentioned that part of the survey was affected by changes in various institutions incident to the federal economy regulations. Reallocation of services, transfer of patients, and other changes made it difficult at times to avoid a duplication of statistical data.

Tuberculosis patients were admitted in 169 federal hospitals, including sixty-five operated by the Veterans Bureau, fifty-two by the Indian Administration, twenty-six by the U S Public Health Service, thirteen by the U S Army, ten by the U S Navy, and three by other federal agencies. There are eighteen sanatoriums exclusively for tuberculosis and 151 departments, some of

which are conducted principally for the treatment of tuberculous patients

Apparently a large number of federal hospitals admit tuberculous patients for diagnosis and temporary care and transfer them later to institutions especially equipped for prolonged tuberculosis hospitalization. The U S Army, for example, transfers its tuberculous patients mainly to the Fitzsimons General Hospital, Denver, and the William Beaumont General Hospital, El Paso, Texas. The U S Navy has no hospital primarily for tuberculosis but utilizes the facilities of the army hospital in Denver. Twenty-six hospitals of the U S Public Health Service have departments for tuberculosis, but only one, the U S Marine Hospital, Fort Stanton, N M., is operated exclusively for the treatment of tuberculous patients. In recent years the Veterans Bureau has decentralized its tuberculosis service to some extent, although it still operates thirteen hospitals principally for tuberculosis.

The U S Department of the Interior can be credited with marked improvements in the tuberculosis service for Indians. Since the survey began the department has opened three new sanatoriums in Arizona and New Mexico, and one has recently been completed in connection with the Minnesota State Sanatorium. Still other hospitals have recently been constructed for the Indian Administration, although not primarily for tuberculosis. The new sanatoriums have replaced old units closed or destroyed by fire within the last few years. Apparently there is need of further construction to replace some of the old sanatorium units still in use.

The number of beds for tuberculosis in the federal hospitals is 10,940, including 328 for children. The sanatoriums have 4,103 beds and the departments 6,837. The Veterans hospitals report 7,734 beds, the Indian hospitals 1,471, the U S Public Health Service 783, the U S Army 630, the U S Navy 176, and other federal institutions 146.

According to the accompanying tabulation there were 15,523 tuberculous patients admitted in the federal departments and sanatoriums, 10,406 discharged and 1,466 deaths. The average daily census of patients was 6,333 and there were 8,375 patients present on the day of reporting.

The federal sanatoriums include six Veterans hospitals, one operated by the U S Public Health Service, and eleven sanatoriums of the Indian Administration. They have a total capacity of 4,103 beds: 2,940 in the sanatoriums of the Veterans Bureau, 893 in the Indian service, and 270 in the tuberculosis sanatorium operated by the U S Public Health Service. The federal sanatoriums admitted 5,078 patients during a twelve months period, treated 7,719, discharged 4,617, and had 590 deaths. The average daily census was 3,179, and there were 3,442 patients present on the day of reporting. The waiting list totaled 150, although at the same time there were 676 vacancies. The average length of stay as reported by fifteen sanatoriums was 172 days.

Seventeen of the federal sanatoriums report facilities for pneumothorax and eighteen have equipment for minor surgery, fifteen for major surgery and thirteen for special chest surgery. Eleven maintain surgical affiliations with other hospitals. Dental departments are furnished in sixteen, including seven which have a full-time dental staff. All the federal sanatoriums have laboratory and x-ray facilities, seventeen have fluoroscopic and stereoscopic equipment, and eight have

necropsy facilities. In necropsy performance the federal sanatoriums with a rate of 25 per cent are surpassed only by the municipal sanatorium group, which reports 37 per cent. The Indian sanatoriums report 16 per cent, the sanatorium operated by the U S Public Health Service 63 per cent, and the sanatoriums of the Veterans Bureau 25 per cent.

There is a considerable variation as regards medical personnel. The six Veterans hospitals exclusively for tuberculosis have eighty-one regular staff members, a ratio of 13.5 per institution. The sanatorium of the U S Public Health Service has six, and the Indian sanatoriums with fourteen regular staff members average only 1.3 per institution. There is considerable variation in the average size of the sanatorium groups, however, and on the basis of capacity the Veterans group has one physician to thirty-six beds, the Indian sanatoriums one to sixty-four, and the sanatorium of the U S Public Health Service one to forty-five. The ratio of physicians to patients is 1.52 in the Indian sanatoriums, 1.36 in the sanatorium of the U S Public Health Service, and 1.28 in the Veterans group.

The federal sanatoriums employ 330 graduate nurses. The ratio of nurses to patients is 1.9 in the Veterans

Federal Departments and Sanatoriums

| | Number of Sanatoriums | Capacity | Number of Departments | Capacity | Total Admis- sions | Patients Discharged | Number of Deaths | Patients Present | Daily Average |

| Totals | 18 | 4,103 | 121 | 6,837 | 15,523 | 10,406 | 1,466 | 8,375 | 6,333 |

group, 1.12 in the Indian sanatoriums, and 1.21 in the tuberculosis hospital of the U S Public Health Service. The total number of employees exclusive of physicians and dentists is 2,079: 1,686 in the Veterans sanatoriums, 146 in the Public Health Service hospital, and 247 in the sanatoriums of the Indian Administration.

The federal tuberculosis departments and sanatoriums, the total valuation of which is approximately \$39,241,495.87, operate on an average daily per capita cost of \$3.20 and have an annual maintenance cost of \$10,553,236.85. The sanatoriums alone represent a valuation of \$12,497,984.18. Their average daily per capital cost is \$2.75 and their maintenance expenditure approximately \$3,150,921.25 a year.

2 State Sanatoriums — There are 65 state sanatoriums with a total capacity of 17,308 beds: 13,333 for adults, 3,170 for children, and 805 unassigned. The institutions vary in size from thirty-two to 1,035 beds and have an average capacity of 266 beds. Twelve states are without a state sanatorium, twenty-one states have one each, six have two, five have three, Maryland, Massachusetts and New York have four each, and Connecticut has five. Three of the sanatoriums in New York were not in operation at the time of the survey.

The total valuation of the state sanatoriums is \$51,046,657.48, based on the general average of \$2,949.31 per bed. These institutions operate on an average daily per capita cost of \$2.01 and expend annually about \$11,559,389.40.

Four hundred and three physicians are connected with the state sanatoriums: sixty-one full-time medical

directors, four part-time medical directors, 187 full-time staff physicians, and 151 attending and consulting physicians. With a regular staff of 252 physicians, the sanatoriums average four physicians per institution and one for every sixty-two patients.

The state sanatoriums have 8,084 other employees: 917 graduate nurses, 308 student nurses, six affiliates, 615 practical nurses, fifty dietitians, seven graduate pharmacists, 113 record clerks, sixty-five x-ray technicians, seventy-nine laboratory technicians, twenty occupational therapists, seventy-five school teachers, eleven social service workers, twenty-five field nurses and 4,551 general employees. The reports show that graduate nurses are employed in sixty-one sanatoriums, practical nurses in forty-one, x-ray technicians in fifty-three, laboratory technicians in fifty, dietitians in forty, and graduate pharmacists in seven. Record clerks are employed in forty-four, occupational therapists in nine-

toriums have a low necropsy percentage: 2,116 deaths and 227 necropsies (11 per cent).

As shown in table 25 the state sanatoriums admitted 19,028 patients: 13,390 adults, 3,541 children, and 1,557 not classified. There were 34,623 patients treated, 18,406 discharged, 15,947 patients present on the day of reporting, and a daily average of 15,756 throughout the year. The average length of stay was 166 days. There were 1,361 vacancies, and the waiting list totaled 6,108.

3 County Sanatoriums—The county sanatoriums constitute the largest group of tuberculosis institutions. They number 173 and have a total capacity of 20,114 beds, 16,029 for adults, 3,165 for children and 920 unassigned. The variation in bed capacity is from ten to 917 beds and the average capacity 116.

These institutions admitted 20,845 patients: 14,128 adults, 3,764 children and 2,953 not classified. They

† Three not in operation at time of survey

teen, school teachers in thirty-four, social service workers in eight, and field nurses in two of the sanatoriums. The total nursing staff is 1,846 and the ratio of nurses to patients 1:9.

Fifty-nine sanatoriums report facilities for pneumothorax, fifty-eight for minor surgery, twenty-one for general major surgery, and twenty-six for special chest surgery. Forty-six maintain surgical affiliations with other hospitals. Dental departments are furnished in forty-eight institutions, eight of which have a full-time staff. Roentgenographic equipment is available in fifty-nine, fluoroscopic facilities in fifty-nine, clinical laboratory departments in fifty-eight, and necropsy facilities in thirty. Fifty-five sanatoriums refer part of their laboratory work and three have affiliations for x-ray service. Fifty-nine sanatoriums, which admitted 18,434 patients, reported 121,654 roentgen examinations and 87,416 fluoroscopic studies. Similarly, fifty-one sanatoriums with 17,227 admissions had 413,106 laboratory examinations. As a group, the state sana-

tories treated 38,000, discharged 19,827 and had 4,017 deaths. They maintained a daily average of 18,364 and had 18,440 patients present on the day of reporting. The waiting list totaled 1,637 patients while, at the same time, there were 1,674 vacancies. The average length of stay in this group was 173 days.

The county sanatoriums are served by a regular staff of 360 physicians—approximately two per institution. There are 106 full-time medical directors and sixty-seven part-time and 187 resident physicians on a full-time basis. The ratio of physicians to patients is 1:51, not counting a group of 813 attending or consulting physicians.

The nursing staff has 2,558 members: 1,499 graduates, 126 student nurses, sixty-six affiliates and 867 practical nurses. The ratio of nurses to patients is therefore, approximately 1:7. Graduate nurses are employed in 167 county sanatoriums and practical nurses in 128. The total number of employees is 8,084 exclusive of physicians and dentists. The personnel

for special departments includes eighty-one dietitians, seven graduate pharmacists, 145 record clerks, 104 x-ray technicians, 119 laboratory technicians, fifty-four occupational therapists, 118 school teachers, forty-four social service workers and ninety-eight field nurses. Laboratory technicians are employed in 100 institutions, x-ray technicians in ninety-five, dietitians in seventy-one, graduate pharmacists in seven, record clerks in ninety-seven, occupational therapists in fifty-two, school teachers in seventy-five, social service workers in twenty-seven, and field nurses in sixty-five of the county sanatoriums.

One hundred and sixty sanatoriums have facilities for pneumothorax and 139 have equipment for minor surgery, fifty-one for major surgery and fifty-nine for special chest surgery. A surgical affiliation is maintained in 130. Dental departments are reported in 114 institutions, including six which have a full-time dental staff. General roentgenographic equipment is furnished in 144 sanatoriums, fluoroscopic facilities in

for children and 193 unassigned. These institutions vary in size from eighteen to 1,446 beds and the average capacity is 335 beds. Together, they represent a valuation of \$29,701,719.30, or \$4,032.82 per bed. The annual maintenance cost of this group is approximately \$5,381,224.20, with an average daily per capita cost of \$2.04.

Pneumothorax facilities are provided in seventeen of these sanatoriums, and equipment for minor surgery in sixteen, for general major surgery in eleven and for special chest surgery in nine. Sixteen institutions maintain surgical affiliations with other hospitals. Four of the sanatoriums that report a dental department have a full-time dental staff. General roentgenographic equipment is furnished in eighteen institutions, fluoroscopic facilities in seventeen, stereoscopic equipment in fifteen and clinical laboratory facilities in nineteen. Ten municipal sanatoriums have necropsy facilities. The necropsy rate, 37 per cent, is the highest percentage in any of the sanatorium groups.

142 and stereoscopic equipment in 132. Thirty-five institutions refer part or all of their x-ray work to other hospitals. In 169 of the sanatoriums there were 18,988 patients admitted, 165,864 roentgen examinations, and 129,192 fluoroscopic studies. Laboratory facilities are available in 144 institutions and necropsy facilities in fifty-two. One hundred and forty-nine county sanatoriums refer part or all of their laboratory work. In 112 institutions reporting 16,809 patients admitted there were 436,562 laboratory examinations performed, or twenty-six per patient. The necropsy rate is 15 per cent, 4,017 deaths and 635 necropsies.

The financial reports indicate that the county sanatorium group operates on an average daily per capita cost of \$2.10 and has an annual maintenance expenditure of approximately \$14,076,006. The total valuation of the county sanatoriums at \$3,737.64 per bed is \$75,178,890.96.

4 Municipal Sanatoriums—Municipally owned sanatoriums are confined to the District of Columbia and the states of Illinois, Maryland, Massachusetts, Michigan, Missouri, New York, Ohio, Pennsylvania and Virginia. There are twenty-two city sanatoriums, with a capacity of 7,365 beds. 6,171 for adults, 1,001

for children and 193 unassigned. These institutions vary in size from eighteen to 1,446 beds and the average capacity is 335 beds. Together, they represent a valuation of \$29,701,719.30, or \$4,032.82 per bed. The annual maintenance cost of this group is approximately \$5,381,224.20, with an average daily per capita cost of \$2.04.

One hundred and two physicians are connected regularly with the municipal sanatoriums—twelve medical directors on full-time duty, ten on part-time, and eighty full-time resident physicians. The ratio of physicians to patients is 1.70 and the average staff membership is 4.6 per institution. The nursing staff in this sanatorium group totals 1,045: 629 graduates, eighteen affiliates and 398 practical nurses. With an average daily census of 7,227, the ratio of nurses to patients is approximately 1.7. The total number of employees is 3,920 exclusive of physicians and dentists. There are twenty-four dietitians employed, eight graduate pharmacists, twenty-nine record clerks, fourteen x-ray technicians, twenty-seven laboratory technicians, fourteen occupational therapists, fifteen school teachers, eight social service workers and 160 field nurses.

The municipal sanatoriums admitted 8,346 patients, treated 15,403, discharged 8,307 and had 1,716 deaths. The daily average according to table 27 was 7,227, and on the day of reporting there were 7,014 patients present. There were 351 vacancies and 228 patients on the waiting list. The average length of stay in this sanatorium group is 170 days per patient.

5 *City-County Sanatoriums*—The city-county institutions constitute the smallest sanatorium group. The sanatoriums, fifteen in all, are located in California, Georgia, Illinois, Kansas, Kentucky, New York, Ohio, Pennsylvania, South Carolina, Tennessee and Texas. Georgia has two, Tennessee two, Texas three, and the other states one each. These institutions vary in size from twenty-four to 462 beds and have an average bed capacity of 161. Their total capacity is 2,423 beds, 1,919 for adults, 480 for children and twenty-four unassigned.

The valuation of the city-county group is reported as \$6,369,848.93, or \$2,628.91 per bed, and the annual

ten of the city-county sanatoriums and necropsy facilities in two. The necropsy rate is only 10 per cent, 573 deaths and fifty-eight necropsies.

A summary of the statistical data as represented in table 28 shows that there were 2,824 patients admitted, 5,113 treated, 2,813 discharged and 573 deaths. The average length of stay in the city-county sanatoriums was 165 days. There were 392 patients on the waiting list and 107 vacancies. The daily average was 2,309, a figure similar to the census of 2,316 patients on the day of reporting.

6 *Private Sanatoriums*—The private sanatoriums comprise a heterogeneous group. They represent

maintenance cost is approximately \$1,466,445.90. The average daily per capita cost is \$1.74.

The regular medical staff has thirty-nine members, or 2.6 per institution. The ratio of physicians to patients is 1:60. The medical director serves on a full-time basis in eight of the sanatoriums.

The nursing staff totals 258 and includes 123 graduates and 135 practical nurses. On the basis of a daily average census of 2,309, the ratio of nurses to patients is 1:9. The total number of employees is 1,023 and includes ten dietitians, one graduate pharmacist, eight record clerks, nine x-ray technicians, ten laboratory

several types of ownership and control and vary greatly in size, type of construction and equipment. In completeness of hospital service they differ widely. Some are hardly beyond the nursing home stage, others, on the contrary, are equipped and staffed to offer a complete and scientific sanatorium service. A few have also gained national prominence because of their scientific accomplishments and their contributions to the progress of medicine.

There are in all 178 private sanatoriums, with a total capacity of 13,684 beds, 8,731 for adults, 892 for children and 4,061 unassigned. They have an average

technicians, two occupational therapists, fifteen school teachers, three social service workers and nine field nurses.

Twelve municipal sanatoriums have facilities for pneumothorax and eleven are equipped for minor surgery, two for general major surgery and five for special chest surgery. Twelve institutions maintain surgical affiliations. Dental departments are furnished in nine sanatoriums, but only one has a full-time dental staff. Ten institutions supply roentgenographic equipment, eleven have fluoroscopic facilities, nine have stereoscopic equipment, and five refer x-ray work to other hospitals. Laboratory equipment is provided in

capacity of seventy-seven beds, the lowest of any group, and vary in size from eight to 487 beds. The capacity is less than twenty-five beds in twenty-eight institutions, from twenty-five to forty-nine beds in forty-four, from fifty to ninety-nine beds in fifty-six, and 100 beds or over in fifty.

One hundred and forty-one sanatoriums which have facilities for pneumothorax report a total of 76,708 treatments. There is equipment for minor surgery in 122, for major surgery in thirty-eight, and for special chest surgery in forty. On the other hand, 118 sanatoriums maintain surgical affiliations. Seventy-three institutions have dental departments, with four main

taining a full-time dental staff X-ray equipment is furnished in 115 of the private sanatoriums, fluoroscopic facilities in 122, and stereoscopic equipment in ninety-two Fifty-six refer x-ray work to other hospitals In 152 institutions there were 10,090 patients admitted, 62,605 x-ray examinations carried out, and 65,892 fluoroscopic studies

Laboratory facilities are furnished in 115 sanatoriums and necropsy facilities in twenty-two Eighty institutions reported 9,104 patients admitted and a total of 208,904 laboratory examinations The private institutions show the lowest necropsy rate of any sanatorium group, namely, 9 per cent 1,911 deaths and 173 necropsies

In the private sanatoriums the ratio of physicians to patients is 1 32 The regular staff of 300 members includes sixty-eight medical directors on full-time duty, ninety on part-time duty and 142 resident physicians

The valuation of the private sanatorium group is \$42,022,469 28, or \$3,070 92 per bed These institutions operate on an average daily per capita cost of \$2 94 and expend annually about \$10,183,719

7 Tuberculosis and Isolation Hospitals—Twenty-six "tuberculosis and isolation" hospitals are included in the list of tuberculosis departments Many of them are operated principally for the treatment of tuberculosis and might well be listed as sanatoriums were it not for the fact that the sanatorium classification has been reserved for those institutions which treat tuberculosis only

Table 30, which lists each institution by name and also the principal features of the tuberculosis service, shows that the tuberculosis and isolation hospitals have a total capacity of 2,556 beds 2,131 for adults, 137 for children and 288 unassigned The admissions for a year total 4,456 including 2,280 adults, 128 children

Other attending or consulting physicians increase the entire staff membership to 1,217

The nursing staff totals 1,324 760 graduates, 104 students, fifty affiliates and 410 practical nurses An average daily census of 9,490 indicates that the ratio of nurses to patients is approximately 1 7 Other trained personnel includes seventy-four dietitians, twenty-three graduate pharmacists 110 record clerks eighty-four x-ray technicians, ninety laboratory technicians, twenty-eight occupational therapists, thirty-two school teachers, nineteen social service workers and eleven field nurses The total number of employees exclusive of physicians and dentists is 4,567

Table 29 shows that the private sanatoriums admitted 14,480 patients 9,485 adults 587 children and 4,408 not classified There were 21,104 patients treated 12,453 discharged and 1,911 deaths The average length of stay was considerably less than in other sanatorium groups, 151 days The private sanatoriums had 9,420 patients present on the day of reporting, a waiting list of 476, and 4,264 vacancies

and 2,048 unclassified There were 3,952 patients discharged, 2,306 patients were present on the day of reporting, and the average daily census was 2,134

Twelve of the hospitals have a full-time staff of forty-five physicians, seventeen employ 459 graduate nurses, and ten are also served by a group of seventy-five student, affiliate and practical nurses The total number of employees in seventeen of the principal hospitals is 1,410, exclusive of physicians

Eighteen hospitals in this group have laboratory departments, fifteen have x-ray equipment, and fourteen have fluoroscopic facilities Apparatus for the administration of artificial pneumothorax is furnished in fourteen

8 Tuberculosis Departments of General Hospitals—As shown in the early part of this report, there are 418 tuberculosis departments connected with general hospitals A considerable number are regular sanatorium units operated in conjunction with the main hospital service Eighty-six hospitals have separate buildings for tuberculosis, in 175 the tuberculosis

departments occupy separate wards or floors, but in 157 the degree of segregation is not known. Three hundred and eleven departments of general hospitals have a capacity of less than twenty-five beds, thirty-eight vary from twenty-five to forty-nine beds, thirty-three have from fifty to ninety-nine beds, and in thirty-six the capacity is 100 beds or over.

Table 31 lists ninety-three of the principal tuberculosis departments of general hospitals which were requested to supply the special data included in the tuberculosis questionnaire. These institutions have a total capacity of 11,942 beds, 9,551 for adults, 701 for children and 1,690 unassigned. They admitted 26,128 patients including 20,583 adults, 885 children and 4,660 not classified. There were 24,627 patients discharged during a twelve months period. This group of hospitals maintained a daily average of 8,927 and on the day of reporting had 9,664 patients under treatment.

Seventy hospitals reported a full-time staff of 373 physicians, an average of five per institution. The

extent to which tuberculosis activities have developed in other hospital fields.

Throughout the survey, every effort was made to obtain as accurate information as possible. The inspection reports were supplemented by a comprehensive tuberculosis questionnaire and the data on the hospitalization of children were later rechecked to determine accurately the classes of patients admitted.

The report is mainly a compilation of factual data and lends itself to comparative studies on the basis of previous surveys. It does not attempt to cover every phase of the tuberculosis service but deals mostly with features that can readily be subjected to a statistical analysis.

This report is presented in the hope that it will be useful to the medical profession, the hospital field and those who are intimately connected with the tuberculosis service in the United States. The completeness of the report is in a large measure due to the loyal and harmonious cooperation of the American Sanatorium

* Partly unclassified

total number of employees exclusive of physicians is 6,785 and includes 1,406 graduate nurses and 717 student, affiliate and practical nurses. These figures cannot be used for comparative purposes, however, for some of the institutions included the entire hospital personnel, whereas others listed only the employees attached to the tuberculosis service.

Eighty-six of this group have x-ray, fluoroscopic and pneumothorax facilities. Laboratory equipment is furnished in eighty-nine.

In all, the tuberculosis departments of general hospitals have a capacity of 14,601 beds. They admitted 37,079 patients during a twelve months period and had 11,318 patients under treatment on the day of reporting.

SUMMARY

1 *General Statement*—The main purpose of this report has been to present to the medical profession a picture of the tuberculosis hospitalization in the United States. The study, therefore, has not dealt with the sanatoriums alone but has been concerned with the

Association, the National Tuberculosis Association and the hospital and sanatorium superintendents, who so generously responded with an unprecedented record of 98.9 per cent returns.

2 *Extent of Tuberculosis Hospitalization*—The report is based on information supplied by 6,200 hospitals including 471 sanatoriums, 740 tuberculosis departments and twenty-nine preventoriums. The total capacity for tuberculosis is 95,198 beds, 64,997 in the sanatoriums, 28,534 in the tuberculosis departments and 1,667 in the preventorium group.

The sanatoriums, tuberculosis departments and preventoriums admitted 121,706 patients during a twelve months period. The number of patients discharged is approximately 118,700 on the basis of 97,381 patients discharged in institutions representing 82 per cent of the bed capacity. The average daily census of patients receiving treatment for tuberculosis is approximately 82,000 for institutions representing 97 per cent of the bed capacity reported, 81,652 patients under treatment. Similarly, from the daily average reported it is esti-

mated that the daily census is 81,952. The accuracy of these figures is again demonstrated by the reports on the number of patients treated. With a daily census of 81,652 patients and 121,706 admissions, there should be approximately 203,358 patients treated during the year. Actually 166,818 were treated in institutions representing 82 per cent of the bed capacity, indicating a total of 203,436 for the entire group. Unfortunately, the number of readmissions and transfers is not known.

3 Cost of Tuberculosis Hospitalization—The sanatoriums, tuberculosis departments and preventoriums represent a total replacement valuation of approximately \$328,937,777.36, or a general average of \$3,455.30 per bed. The sanatorium group averages \$3,335 per bed, with the institutions of 100 beds or over averaging \$3,498. In view of these figures it appears that it should be possible to keep the cost of sanatorium construction well below \$6,000 or \$7,000 per bed. To expend from \$8,000 to \$12,000 per bed, as some institutions have done, seems an unwarranted extravagance in the use of public and private funds. By limiting construction to essential needs, there will be more funds available for the actual care of patients.

The annual cost of tuberculosis hospitalization in the United States exceeds \$70,000,000, a sum that emphasizes the magnitude of the tuberculosis problem as it still exists. The average cost of maintaining a tuberculous patient in the sanatoriums is \$2.37 a day, in the tuberculosis departments \$2.95, and in the preventoriums \$1.39.

4 Tuberculosis Hospitalization in General Hospitals—The tuberculosis departments of general hospitals, 418 in all, have a capacity of 14,601 beds. Many of them are regular sanatorium units, whereas others admit patients primarily for diagnosis and temporary care. As a whole, the group plays an important part in the control of tuberculosis for there were 37,079 tuberculous patients admitted in general hospitals during a one year period.

The practice of supplementing sanatorium facilities with tuberculosis departments in general hospitals has been indorsed by the American Medical Association, the American Hospital Association and the National Tuberculosis Association. The endorsement, however, embodies a requirement of adequate segregation for the protection of other patients and personnel. General hospitals continually admitting patients in need of segregation would benefit by the establishment of an isolation department not only for contagious diseases but also for tuberculosis, meningitis, encephalitis, pneumonia and other respiratory infections. By providing facilities of this type, general hospitals would be in position to offer complete community service.

5 Preventorium Service—The prevention of tuberculosis among children has been a subject of much concern during recent years. Local agencies have worked diligently to provide for the care of undernourished children and tuberculous contacts, summer camps have been established as a general health measure, preventoriums have been built, and many sanatoriums have entered into the preventive phase of tuberculosis control. Thus, there are at present 230 sanatoriums which admit children including 161 where childhood tuberculosis, contacts and other nontuberculous children are accepted.

The sanatoriums reported on the condition of 12,629 children and showed that 6,659 had the childhood type, 824 were extrapulmonary cases, 3,236 were nontuber-

culous, and 701 were unclassified. The preventoriums in reporting on 2,479 patients showed that twelve were adult type tuberculosis, 424 childhood type, twenty-four extrapulmonary, 1,326 nontuberculous and 693 unclassified.

The preventorium service today is the culmination of a well organized antituberculosis program. In invading the sanatorium field it should not be permitted to interfere with the primary function of the sanatoriums, which is the hospitalization of tuberculous patients. The preventorium service defeats its own purpose when it allows the admission of tuberculous contacts and childhood tuberculosis to the exclusion of open pulmonary cases.

6 Rehabilitation—Rehabilitation has not kept pace with the preventive and curative phases of the sanatorium service. Only fifty-three sanatoriums have made efforts to establish vocational rehabilitation as an aid to economic recovery. Two hundred and forty-one sanatoriums, however, have instituted programs of graduated exercise to insure a complete physical recovery and restore patients to a normal social life. In only five states is there an organized rehabilitation service under a bureau of vocational education. The problem, as a whole, is well worthy of further study. It is concerned with the cost of tuberculosis hospitalization and with the responsibility of individual institutions in the postsanatorium care of patients. Likewise, it involves the community's responsibility toward patients who remain physically handicapped and unable to compete on even terms in industry and other occupations.

7 Medical Staff—The tuberculosis sanatoriums have a regular staff of 1,154 physicians and report an attending or consulting staff of 2,195. Twenty-six tuberculosis and isolation hospitals report a full-time staff of forty-five physicians, and ninety-three tuberculosis departments of general hospitals have 373 on full-time duty. The ratio of physicians to patients is 1:28 in the Veterans hospitals exclusively for tuberculosis, 1:52 in the Indian sanatoriums and 1:36 in the tuberculosis hospital operated by the U. S. Public Health Service. In the civilian sanatoriums the ratio is 1:62 in the state institutions, 1:51 in the county, 1:70 in the municipal, 1:60 in the city and county, and 1:32 in the private sanatoriums.

In fifty-two sanatoriums the medical staff participates in the training of medical students. Interns receive tuberculosis training in sixty-three sanatoriums and in 159 approved internship hospitals. Ninety-three sanatoriums and forty-four tuberculosis departments afford training for resident physicians, and sixty-seven sanatoriums offer postgraduate courses. Undoubtedly, many other sanatoriums are in position to establish centers of postgraduate training.

8 Medical Facilities—It has been shown in the report that 406 sanatoriums have facilities for pneumothorax, 364 have equipment for minor surgery, 138 for major surgery and 152 for special chest surgery. Three hundred and thirty-three sanatoriums maintain surgical affiliations with other institutions. Dental departments are furnished in 273 sanatoriums, x-ray equipment in 350, fluoroscopic facilities in 363, and stereoscopic equipment in 316. One hundred and five refer part or all of their x-ray work to other hospitals. Three hundred and eighty-one sanatoriums have clinical laboratory facilities, but 375 refer part or all of their laboratory work to outside departments. Only 124 have facilities for necropsy work.

SUMMARY BY STATES

ALABAMA

In 1934 there were 2942 cases of tuberculosis reported in Alabama, 1611 deaths from pulmonary tuberculosis and 1734 deaths from all forms. The tuberculosis death rate which averaged 101.5 per hundred thousand during the period 1915 to 1924 and 83.6 from 1925 to 1934 decreased to 62.6 in 1934. At present the state department of public health has 9,257 cases of adult type tuberculosis on record.

Alabama has 462 beds for tuberculosis. 242 sanatorium beds, 53 in three general hospitals operated by the federal government, 80 in state mental hospitals and 87 in a state penal institution. There are 426 beds for adults and 36 for children. During the annual period covered by this report there were 969 tuberculous patients admitted, 286 in the sanatoriums, 521 in the federal hospitals, 98 in state institutions and 64 in a private general hospital. At present there are 327 patients under treatment, 175 in the sanatoriums, 43 in the federal hospitals, 66 in the state mental institutions and 42 in the state convict tuberculosis hospital.

There are four sanatoriums in the state, three county and one private. Two sanatoriums have x-ray facilities and three have laboratory equipment. All have facilities for artificial pneumothorax. There were 1,245 pneumothorax treatments given during a twelve months period. Only one sanatorium reports an outpatient department but the state operates an efficient diagnostic service in the form of traveling clinics which can examine more than 5,000 patients annually.

The tuberculosis institutions in Alabama have a replacement valuation of approximately \$1,450,565.67. Their annual maintenance expenditure is \$338,853.63. The sanatoriums are valued at \$611,415.93 and expend annually about \$112,858.63.

One new sanatorium has been opened since the survey was completed, namely the Morgan County Sanatorium, Decatur, an institution of fifteen beds.

ARIZONA

Reports from the state board of health indicate that Arizona had 1,042 deaths from pulmonary tuberculosis in 1934 and 1,075 deaths from all forms. The tuberculosis death rate was 334 in 1923 and 237.3 in 1933. New cases of tuberculosis reported in 1934 total 1,178. The high mortality rate from tuberculosis is of course attributable to the fact that a large number of patients enter the state on account of the favorable climatic conditions.

Arizona has 1,518 beds for tuberculosis, 805 sanatorium beds, ten beds in a separate preventorium and 703 beds in tuberculosis departments of other hospitals. There are eighteen sanatoriums in the state, four Indian, two county and twelve private.

The federal sanatoriums have 256 beds, the county sanatoriums 82 and the private sanatoriums 467. Eight of the sanatoriums have x-ray facilities, nine have fluoroscopic equipment, seven have clinical laboratories and nine have facilities for pneumothorax. A total of 2,829 pneumothorax treatments was reported.

Sixteen general hospitals have a capacity of 703 beds for tuberculosis. These include two Veterans hospitals with 575 beds, three county institutions with 25 beds and four private hospitals with 103 beds. Seven general hospitals of the Indian Administration which did not specify the number of beds for tuberculosis admitted 204 tuberculous patients and had 43 under treatment on the day of reporting.

During the twelve months period covered by this report there were 2,209 tuberculous patients admitted, 1,018 in the sanatoriums and 1,191 in the tuberculosis departments. The average daily census of patients was 788 and there were 1,004 patients present in all tuberculosis institutions on the day of reporting. The Veterans hospitals admitted 627 tuberculous patients, the sanatoriums and hospital departments of the Indian Administration admitted 696, the county sanatoriums and hospitals admitted 103 and the sanatoriums and tuberculosis departments under private control admitted 783.

Only one sanatorium has an outpatient department. Three tuberculosis clinics were reported, however, one in Phoenix, one in Tucson and one in Prescott.

The tuberculosis institutions in Arizona have a replacement valuation of approximately \$5,716,949.59. Their annual maintenance expenditure is \$1,357,390.45. The sanatoriums are valued at \$2,306,331.90 and expend annually about \$480,768.29.

One new sanatorium has been opened since the survey was completed, namely the Welfare Sanatorium, Tempe, a federal institution of 110 beds.

ARKANSAS

The Arkansas State Board of Health reported 1,450 new cases of tuberculosis in 1933, 1,011 deaths from pulmonary tuberculosis and 1,071 deaths from all forms. The tuberculosis death rate at that time was 54 per hundred thousand.

Arkansas has 790 beds for tuberculosis, 556 sanatorium beds and 234 beds in tuberculosis departments of other hospitals. There are two sanatoriums in the state, one for white and one for Negro patients. These institutions operated by the state have 556 beds including thirty-two in the Negro division.

Three federal hospitals have eighty-two beds for tuberculosis, the state hospital for mental diseases has 100, a state penal institution has eight and two county hospitals have forty-four.

The sanatoriums are staffed by full-time medical personnel. They have x-ray, fluoroscopic and laboratory equipment and have facilities for artificial pneumothorax. A total of 4,354 pneumothorax treatments was reported.

During the twelve months period covered by this report there were 834 patients admitted, 1,378 treated and 801 discharged. The average daily census of patients was 570 and there were 653 patients present

in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 749 patients and the tuberculosis departments 85.

The larger state sanatorium conducts an outpatient department. The state tuberculosis association and county health officers cooperate in school surveys and tuberculosis clinics throughout the state. Approximately 6,000 children were tuberculin tested in 1934. Regular tuberculosis clinics are maintained in Little Rock (Pulaski County). In the other counties there are diagnostic clinics occasionally.

The tuberculosis institutions in Arkansas have a replacement valuation of approximately \$1,632,475.48. Their annual maintenance expenditure is \$511,012.30. The sanatoriums are valued at \$820,840.28 and expend annually about \$270,635.80.

CALIFORNIA

Reports from the state board of health show that California had 4,115 deaths from pulmonary tuberculosis in 1934 and 4,609 deaths from all forms. The tuberculosis death rate was 74.8. New cases of tuberculosis reported in 1934 total 8,793.

California has 7,389 beds for tuberculosis, 4,016 sanatorium beds, 418 beds in separate preventoriums and 2,955 beds in tuberculosis departments of other hospitals. There are thirty-six sanatoriums in the state, one federal, ten county, one city and county, and twenty-four private. Additional tuberculosis facilities are available in thirty-eight general hospitals (2,551 beds), one orthopedic hospital, six mental institutions (317 beds), three penal institutions (sixty-five beds), one industrial hospital, one county institution (sixteen beds) and one convalescent hospital (six beds).

Federal hospitals have 1,102 beds for tuberculosis. These include four Veterans hospitals (884 beds), one army hospital (twenty beds), three naval hospitals (145 beds), a United States Marine Hospital (fifty-three beds) and three Indian hospitals, one of which reported thirty beds for tuberculosis.

The county sanatoriums have a capacity of 2,300 beds, and there are 1,268 beds for tuberculosis in twenty general hospitals under county control and sixteen beds in the tuberculosis unit of a county home. One sanatorium under city and county control has eighty-two beds and a general hospital under the same management has 415.

The bed capacity in twenty-four private sanatoriums is 1,390. Ten other private institutions including seven general hospitals have twenty-eight beds for tuberculosis.

Of the thirty-six sanatoriums, twenty-six have x-ray facilities, twenty-eight have fluoroscopic equipment, thirty have clinical laboratories and thirty-one have facilities for pneumothorax. A total of 31,226 pneumothorax treatments were reported.

During the twelve months period covered by this report there were 10,093 patients admitted, 13,702 treated and 8,010 discharged. The average daily census of patients was 5,518 and there were 6,037 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 3,948 patients, the tuberculosis departments 5,369 and the preventoriums 776. In 1934 the state subsidized 4,118 patients in twenty-eight county sanatoriums and hospitals.

Twelve sanatoriums report an outpatient department. This service is supplemented by tuberculosis clinics and school surveys conducted by county and city health units.

The tuberculosis institutions in California have a replacement valuation of approximately \$18,586,626.03. Their annual maintenance expenditure is \$5,978,423.44. The sanatoriums are valued at \$10,061,468.87 and expend annually about \$2,846,682.40.

COLORADO

Reports from the state tuberculosis association indicate that Colorado had 819 deaths from pulmonary tuberculosis in 1933 and 873 deaths from all forms. The tuberculosis death rate was 168.5 in 1923 and 83.0 in 1933. New cases of tuberculosis reported in 1934 total 846.

Colorado has 2,691 beds for tuberculosis, 1,743 sanatorium beds and 948 in tuberculosis departments of other hospitals. There are no public sanatoriums in the state of Colorado but seventeen private sanatoriums are in operation which vary in capacity from sixteen to 301 beds. Three federal hospitals admit tuberculous patients. These include one Indian hospital, the Veterans Administration Facility at Fort Lyon, recently converted into a mental hospital and the Fitzsimons General Hospital which has 536 beds for tuberculosis.

A state hospital for mental diseases has thirty-four tuberculosis beds and a state penal institution reports five. One county hospital reports seven beds for tuberculosis and a general hospital under city and county control has eighty. Nine general hospitals which are privately owned have allocated 286 beds to the tuberculosis service.

Of the seventeen sanatoriums, eleven have x-ray facilities, twelve have fluoroscopic equipment, eleven have clinical laboratories and fifteen have pneumothorax facilities. A total of 5,382 pneumothorax treatments was reported.

During the twelve months period covered by this report there were 2,507 patients admitted and 2,350 discharged. The average daily census of patients was 1,681 and there were 1,819 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 1,137 patients and the tuberculosis departments 1,370. The sanatoriums discharged 1,139 patients including 132 deaths; they maintained a daily average of 1,033 and had 1,034 patients present on the day of reporting.

Four sanatoriums conduct outpatient departments. The city of Denver maintains a tuberculosis clinic and there are other clinics throughout the state sponsored by the state tuberculosis association and local medical societies. Permanent tuberculosis clinics are also conducted by physicians in Colorado Springs and Pueblo.

The tuberculosis institutions in Colorado have a replacement valuation of approximately \$10 632 096 32. Their annual maintenance expenditure is \$2,566,029 89. The sanatoriums are valued at \$7 527,837 84 and expend annually about \$1 304 950 51.

One new sanatorium has been opened since the survey was completed namely the Black Forest Sanitarium, Colorado Springs a federal institution of fifty beds.

CONNECTICUT

Reports from the state tuberculosis association indicate that Connecticut had 654 deaths from pulmonary tuberculosis in 1934 and 723 deaths from all forms. The tuberculosis death rate was 75.2 in 1925 and 42.6 in 1934. New cases of tuberculosis reported in 1934 total 1,312.

Connecticut has 1 915 beds for tuberculosis 1 675 sanatorium beds and 240 beds in tuberculosis departments of other hospitals. There are seven sanatoriums in the state, five state institutions and two privately owned.

The state sanatoriums have 1 483 beds and the private sanatoriums have 192.

Other institutions that have tuberculosis departments include three general hospitals with forty eight beds two tuberculosis and isolation hospitals with fifty-six beds and two mental institutions with 136 beds for tuberculosis.

During the twelve months period covered by this report there were 1 676 patients admitted, 3 082 treated and 1 521 discharged. The average daily census of patients was 1 571 and there were 1 674 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 1 314 patients and the tuberculosis departments 362.

All sanatoriums have x ray, fluoroscopic and laboratory facilities, and six are equipped for pneumothorax. (One sanatorium admits extra pulmonary cases only.) A total of 14 686 pneumothorax treatments was reported.

The state sanatoriums conduct outpatient and diagnostic clinics under the auspices of the state tuberculosis commission. Districts are assigned to each institution, so that the entire state is covered. In five cities the tuberculosis clinics are operated by local agencies.

The tuberculosis institutions in Connecticut have a replacement valuation of approximately \$5 511 717 67. Their annual maintenance expenditure is \$1 835,263 55. The sanatoriums are valued at \$4 550 808 16 and expend annually about \$1 511,573 81.

DELAWARE

The Delaware State Board of Health reported 155 deaths from all forms of tuberculosis in 1934 at which time the tuberculosis death rate was 65 per hundred thousand. In that same year there were 178 new cases of tuberculosis reported.

Delaware has two state sanatoriums, one for white and one for Negro patients. Their capacity is 121 and forty beds, respectively. This includes forty four beds for children. Tuberculous patients are also admitted in the state mental hospital and there are twenty two beds available in a private preventorium.

During the twelve months period covered by this report there were 149 patients admitted 268 treated and 93 discharged. The average daily census of patients was 149, and there were 152 patients present on the day of reporting. The sanatoriums admitted 109 patients, and the state mental hospital five.

The state sanatoriums maintained a daily average of 129 and had a census of 139 patients when reporting. They discharged 93 patients and had 31 deaths. Both institutions are equipped for pneumothorax and reported 3 783 treatments.

The larger institution conducts an outpatient department and there are tuberculosis clinics throughout the state conducted by the sanatorium staff and the state health department.

The tuberculosis institutions in Delaware have a replacement valuation of approximately \$400 127 83. Their annual maintenance expenditure is \$156 790. The sanatoriums are valued at \$355 973 83 and expend annually about \$147 000.

DISTRICT OF COLUMBIA

The District of Columbia has 666 beds for tuberculosis 220 in the Tuberculosis Hospital 150 in the Children's Tuberculosis Sanatorium 100 in the Gallinger Municipal Hospital 50 in three general hospitals under federal control and 146 in a federal hospital for mental diseases.

These institutions and two private hospitals admitted 1,107 patients. Of this number 417 were admitted to the federal hospitals which draw their patients from outside areas. The Gallinger Municipal Hospital admitted 321 tuberculous patients, the Tuberculosis Hospital admitted 210 and the Children's Sanatorium (recently opened) had received 122.

Reports from the District Board of Health and the local tuberculosis association indicate that there were 520 deaths from pulmonary tuberculosis in 1934 and 609 from all forms. In 1924 the tuberculosis death rate was 115.0 per hundred thousand. It increased to 123.0 in 1934. There were 1 138 new cases of tuberculosis reported in the District in 1934.

The sanatoriums and tuberculosis departments have a replacement valuation of approximately \$2 647 606 13 and expend annually about \$327 051 80. The sanatoriums are valued at \$1 125 000. Plans are now in progress for a new tuberculosis sanatorium for adults.

A summer camp for children is maintained by the local tuberculosis association which also cooperates with the health department in providing a tuberculosis clinic service for children.

FLORIDA

Florida has 330 beds for tuberculosis. There are three sanatoriums in the state two county and one private which have a capacity of eighty-six beds. Two private preventoria have forty-six beds and there are 198 beds in the tuberculosis departments of two federal hospitals three state institutions two county hospitals a county home, three municipal hospitals and three private hospitals.

Recently a number of small county sanatoriums have opened with federal aid and the Florida Tuberculosis Board has filed application for federal funds to construct five district tuberculosis hospitals.

Reports indicate that Florida had 959 deaths from pulmonary tuberculosis in 1933 and 1 039 deaths from all forms. The tuberculosis death rate, which was 87.2 in 1927 decreased to 66.9 in 1933. There were 661 new cases of tuberculosis reported in 1933 and 603 in 1934. During the annual period covered by this report the sanatoriums admitted forty eight patients the tuberculosis departments 312 and the preventoria 520.

GEORGIA

Georgia has 1,285 beds for tuberculosis 645 sanatorium beds (153 for children), 13 beds in a separate preventorium and 627 beds in tuberculosis departments of other hospitals. There are five sanatoriums, one state one county, two city and county, and one private. Two mental institutions, one state and one federal have 512 beds for tuberculosis two penal institutions one state and one federal, have eighty-one beds and four general hospitals three federal and one private, have thirty four beds.

Reports from the state tuberculosis association show 3 647 new cases reported in 1934 and 1,736 deaths from all forms of tuberculosis. The tuberculosis death rate was 81.5 in 1920 and 57.7 in 1934.

There were 1,501 patients admitted 1 222 in the sanatoriums 251 in the tuberculosis departments and 28 in the preventorium. The sanatoriums maintained a daily average of 553 patients and had 561 present on the day of reporting. They treated 1,458 patients discharged 910 and had 109 deaths. A day's census in all tuberculosis institutions was 1 109.

Three sanatoriums maintain x ray departments four have laboratory equipment and four have pneumothorax facilities. A total of 4 459 pneumothorax treatments was administered.

The state sanatorium maintains an outpatient department, and a field control survey has been established by the state department of public health. In 1934 there were 185 clinics held in 222 counties and 10 635 examinations made.

The sanatoriums are valued at \$936 243 50 and expend annually about \$325,277 65. All tuberculosis facilities in the state are valued at \$3 337 320 26 and the annual maintenance expenditure in the sanatoriums and tuberculosis departments is approximately \$972 448 16.

IDAHO

Idaho has one sanatorium a 132 bed institution for Indian children. There are twenty four tuberculosis beds in the Veterans Administration Facility at Boise and twelve beds in the Idaho State Soldiers Home Hospital. Three general hospitals have forty eight beds for tuberculosis. The admission of tuberculous patients is also reported by two other general hospitals.

The state department of public welfare and the state tuberculosis association reported 109 deaths from pulmonary tuberculosis in 1934 and 130 deaths from all forms. The tuberculosis mortality rate was 46.4 in 1921, 36.5 in 1933 and 29.13 in 1934.

During the annual period under consideration there were 197 tuberculous patients admitted in the Indian sanatorium nineteen in the Veterans Administration Facility, and seventy in private general hospitals. There were 171 tuberculous patients present in these institutions on the day of reporting.

ILLINOIS

Reports from the state board of health and the state tuberculosis association indicate that Illinois had 3 711 deaths from pulmonary tuberculosis in 1934 and 4 102 deaths from all forms. The tuberculosis death rate was 52 per hundred thousand in 1934. New cases of tuberculosis reported in 1934 total 9 743.

Illinois has 5 404 beds for tuberculosis 3 478 sanatorium beds 24 beds in a separate preventorium and 1 902 in tuberculosis departments of other hospitals. There are twenty six sanatoriums in the state sixteen county, two municipal one city and county, and seven private.

The county sanatoriums have 1 486 beds the municipal sanatoriums 1 299 the city and county sanatoriums 110 and the private sanatoriums 583.

Other institutions that have tuberculosis departments include nineteen general hospitals (710 beds) three orthopedic hospitals (225 beds) eleven mental institutions (934 beds) and three penal institutions (thirty three beds).

During the twelve months period covered by this report there were 6 430 patients admitted 9 281 treated and 5 833 discharged. The average daily census of patients was 3 600 and there were 4 935 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 3 920 patients and the tuberculosis departments 2 510.

Of the twenty six sanatoriums twenty three have x ray facilities twenty two have fluoroscopic equipment twenty four have laboratory departments and twenty four have facilities for pneumothorax. These institutions reported a total of 17 143 pneumothorax treatments. Sixteen sanatoriums have outpatient departments. The City of Chicago Municipal Tuberculosis Sanitarium which also operates the Municipal Home for Open Cases has recently established a pneumothorax clinic in the old Iroquois Memorial Hospital Chicago. Tuberculosis clinics are carried out in the majority of counties by the sanatorium staffs.

The tuberculosis institutions in Illinois have a replacement valuation of approximately \$18 616 110.27. Their annual maintenance expenditure is \$4 894 161 49. The sanatoriums are valued at \$10 126 690 59 and expend annually about \$2 902 685 54.

INDIANA

Indiana has 1,586 beds for tuberculosis 1,357 sanatorium beds and 229 in tuberculosis departments of other hospitals. There are nine sanatoriums in the state one state and eight county.

The state sanatorium has 211 beds and the county sanatoriums have 1 146.

There are facilities for tuberculosis in four general hospitals five mental institutions (179 beds) and three penal institutions (forty-two beds). The tuberculosis departments represent four federal hospitals, seven state institutions and one private hospital.

Reports from the state board of health and the state tuberculosis association indicate that Indiana had 1 552 deaths from pulmonary tuberculosis in 1934 and 1 788 deaths from all forms. The tuberculosis death rate was 54.2 in 1934. New cases of tuberculosis reported in 1934 total 1 723.

During the twelve months period covered by this report there were 1 698 patients admitted 1 542 in the sanatoriums and 156 in the tuberculosis departments. The sanatoriums averaged 1 182 patients per day they treated 2 763 discharged 1 553 and had 218 deaths. There were 1 401 patients present in all tuberculosis institutions on the day of reporting.

All the sanatoriums have equipment for x ray and fluoroscopic examinations and eight maintain laboratory departments. All are equipped for pneumothorax and reported a total of 7 741 treatments. Seven maintain outpatient departments. Tuberculosis clinics are carried out by the sanatorium staffs and the state department of health. Sixty-five clinics were reported in fifty-three counties. Home visits are made by public health nurses in seventy-seven counties.

The tuberculosis institutions in Indiana have a replacement valuation of approximately \$5 432 341.42. Their annual maintenance expenditure is \$1 011 911.77. The sanatoriums are valued at \$4 558 862.83 and expend annually about \$776 671.52.

IOWA

Reports from the state tuberculosis association indicate that Iowa had 520 deaths from pulmonary tuberculosis in 1934 and 619 deaths from all forms. The tuberculosis death rate was 24.9 in 1934. New cases of tuberculosis reported in 1934 total 455.

Iowa has 981 beds for tuberculosis 774 sanatorium beds and 207 in tuberculosis departments of other hospitals. There are six sanatoriums in the state one Indian one state and four county.

The Indian sanatorium has eighty beds the state sanatorium 363 and the county institutions 331.

There are tuberculosis departments in four general hospitals (fifty beds) seven mental institutions (145 beds) and two penal institutions (twelve beds). Two federal hospitals report seventy-seven beds and five state institutions 130.

During the annual period covered by this report there were 881 patients admitted 1 324 treated and 641 discharged. The average daily census of patients was 660 and there were 976 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 618 patients and the tuberculosis departments 263.

All the sanatoriums have x ray fluoroscopic laboratory and pneumothorax equipment. They administered a total of 5 075 pneumothorax treatments. One sanatorium reports an outpatient department. A tuberculosis clinic is conducted at the Broadlawn Polk County Public Hospital and eighteen clinics were conducted by the tuberculosis association in 1934 in cooperation with county medical societies.

The tuberculosis institutions in Iowa have a replacement valuation of approximately \$3 040 173.87. Their annual maintenance expenditure is \$766 837.02. The sanatoriums are valued at \$2 250 610.25 and expend annually about \$554 196.27.

KANSAS

Kansas has 571 beds for tuberculosis 388 sanatorium beds and 183 in tuberculosis departments of other hospitals. There are three sanatoriums one state one county and one city and county.

The state sanatorium has 268 beds and the other sanatoriums have sixty beds each. Tuberculosis facilities are also available in four federal hospitals four state institutions and nine private hospitals. This group contains ten general hospitals three mental institutions two penal institutions one Indian school and one convalescent hospital.

Reports from the state department of health indicate that Kansas had 478 deaths from pulmonary tuberculosis in 1934 and 533 deaths from all forms. The tuberculosis death rate was 41.7 in 1924 and 27.9 in 1934. New cases of tuberculosis reported in 1934 total 902.

There were 742 patients admitted 426 in the sanatoriums and 316 in the tuberculosis departments. The sanatoriums treated 754 discharged 401 and maintained an average daily census of 354. There were 542 patients present in all tuberculosis institutions on the day of reporting.

The state sanatorium maintains an outpatient department and conducts monthly tuberculosis clinics at Lawrence and in other localities with the cooperation of the state tuberculosis association.

The tuberculosis institutions in Kansas have a replacement valuation of approximately \$1 765 936.23. Their annual maintenance expenditure is \$451 204.63. The sanatoriums are valued at \$1 067 916.22 and expend annually about \$263 217.88.

KENTUCKY

The state of Kentucky has 1 206 beds for tuberculosis 949 sanatorium beds and 257 in tuberculosis departments of other hospitals. There are four sanatoriums in the state one federal one state one county and one city and county.

The federal sanatorium has 375 beds the state 80 the county 90 and the city and county 404. There are 112 beds for children. Seven general hospitals admit tuberculous patients one county institution has twenty beds for tuberculosis and two mental institutions have 222.

There were 2 092 deaths from pulmonary tuberculosis in 1933 and 2 315 deaths from all forms according to a report from the state tuberculosis association. The tuberculosis death rate was 87.4 in 1933. New cases of tuberculosis reported in 1934 total 1 310.

During the twelve months period covered by this report there were 1 884 tuberculous patients admitted 2 389 treated and 1 442 discharged. The average daily census of patients was 914 and there were 1 077

patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 1 580 patients and the tuberculosis departments 304.

The sanatoriums are all equipped with x ray fluoroscopic, laboratory and pneumothorax facilities. They reported 10 487 pneumothorax treatments. Two maintain outpatient departments and reports indicate that seventy-one county health departments are also conducting tuberculosis clinics. One hundred and sixty health nurses are available for home visits and clinic service.

The tuberculosis institutions in Kentucky have a replacement valuation of approximately \$4 297 518.30. Their annual maintenance expenditure is \$1 050 491.57. The sanatoriums are valued at \$3 317 238.83 and expend annually about \$786 488.32.

LOUISIANA

The Louisiana State Board of Health reported 1 398 deaths from pulmonary tuberculosis in 1934 and 1 313 deaths from all forms. The tuberculosis death rate was 113.4 in 1924 and 70.2 in 1934. New cases of tuberculosis reported in 1934 total 1 599.

Louisiana has 1 053 beds for tuberculosis 326 sanatorium beds and 727 in tuberculosis departments of other hospitals. There are three sanatoriums one state and two private.

The state sanatorium has ninety-six beds and the private sanatoriums have 230.

Four general hospitals have 577 beds for tuberculosis and two state mental institutions are hospitalizing at present 200 tuberculous patients. The state charity hospitals at New Orleans and Shreveport have a combined tuberculosis capacity of 371 beds the United States Marine Hospital at New Orleans has 49 beds for tuberculosis and the Veterans Administration Facility at Alexandria has 157 beds.

During the twelve months period covered by this report there were 836 patients admitted 1 084 treated and 761 discharged. The average daily census of patients was 343 and there were 566 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 297 patients and the tuberculosis departments 539.

The tuberculosis institutions in Louisiana have a replacement valuation of approximately \$3 413 143.61. Their annual maintenance expenditure is \$844 565.82. The sanatoriums are valued at \$820 851 and expend annually about \$116 267.57.

The Gowen Sanatorium Shreveport a private institution of fifteen beds has been opened since the survey was completed.

MAINE

The Department of Health and Welfare of the State of Maine reported 300 deaths from pulmonary tuberculosis in 1933 and 367 deaths from all forms. The tuberculosis death rate was 68.4 in 1924 and 45.5 in 1933. New cases of tuberculosis reported in 1934 total 640.

Maine has 576 beds for tuberculosis including eighty-one for children. There are four sanatoriums in the state with a capacity of 483 beds. The three state sanatoriums have 452 beds and one private sanatorium has thirty.

Tuberculosis facilities are also available in three mental institutions and seven general hospitals three federal and four private.

During the twelve months period covered by this report there were 616 patients admitted 939 treated and 515 discharged. The average daily census of patients was 459 and there were 498 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 491 patients and the tuberculosis departments 125.

All the sanatoriums have x ray fluoroscopic, laboratory and pneumothorax facilities. A total of 3 563 pneumothorax treatments was administered. Outpatient departments are maintained in three of the sanatoriums. Additional tuberculosis clinics and school surveys were inaugurated in January 1935.

The tuberculosis institutions in Maine have a replacement valuation of approximately \$1 389 221.38. Their annual maintenance expenditure is \$516 171.62. The sanatoriums are valued at \$1 030 675.58 and expend annually about \$419 610.12.

MARYLAND

The state department of health reported 1 233 deaths from pulmonary tuberculosis in 1934 and 1 384 deaths from all forms. The tuberculosis death rate was 121.8 in 1925 and 78.1 in 1934. New cases of tuberculosis reported in 1934 total 2 590.

Maryland has 1 550 beds for tuberculosis 1 350 sanatorium beds and 200 in tuberculosis departments of other hospitals. There are eight sanatoriums four state owned one municipal and three private.

The state sanatoriums have 896 beds the municipal 179 and the private sanatoriums 275.

Tuberculosis facilities are also available in a general hospital of the United States Public Health Service, a Veterans hospital for mental diseases four state mental institutions two penal institutions and three private hospitals.

During the twelve months period covered by this report there were 2 064 patients admitted 1 956 in the sanatoriums and 108 in the tuberculosis departments. The sanatoriums treated 3 155 patients, discharged 1 857 and maintained an average daily census of 1 302. There were 1 537 patients present in all tuberculosis institutions on the day of reporting.

Seven of the sanatoriums have x ray fluoroscopic laboratory and pneumothorax facilities. None of the sanatoriums report an outpatient department but many participate in the clinic service throughout the state. There were 458 clinics held in 1934 and 41 355 home visits were made by health nurses.

The tuberculosis institutions in Maryland have a replacement valuation of approximately \$4 311 346.40. Their annual maintenance expenditure is \$917 955.57. The sanatoriums are valued at \$3 548 483 and expend annually about \$712 505.57.

MASSACHUSETTS

Reports from the department of public health indicate that Massachusetts had 1,902 deaths from pulmonary tuberculosis in 1934 and 2,116 deaths from all forms. The tuberculosis death rate was 86.1 in 1934 and 48.7 in 1934. New cases of tuberculosis reported in 1934 total 3,580.

Massachusetts has 5,350 beds for tuberculosis, 4,063 sanatorium beds, 30 beds in a separate preventorium and 1,257 beds in tuberculosis departments of other hospitals. There are twenty-three sanatoriums in the state, one federal, four state, seven county, four municipal and seven private.

The federal sanatorium has 472 beds, the state sanatoriums have 1,341, the county sanatoriums 1,176, the municipal sanatoriums 744 and the private sanatoriums 430. The sanatorium list does not include the tuberculosis division of the Fall River General Hospital or the tuberculosis departments of five isolation and tuberculosis hospitals, namely the Board of Health Hospital, Brookline, the Lowell Tuberculosis Hospital, the Barnstable County Sanatorium, Pocasset, the Health Department Hospitals, Springfield and Belmont Hospital, Worcester. These six hospitals have a total capacity of 845 beds. Their tuberculosis departments, which have a combined capacity of 418 beds, admitted 651 patients, treated 992, discharged 594 and maintained an average daily census of 359. They had 333 patients present on the day of reporting.

Twenty-seven other hospitals have facilities for tuberculosis, including ten state institutions for mental diseases (327 beds). There is one preventorium, a private institution of thirty beds.

During the twelve months period covered by this report there were 4,858 patients admitted, 8,323 treated and 4,342 discharged. The average daily census of patients was 3,992 and there were 4,679 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 3,426 patients, the tuberculosis departments 1,237 and the preventorium 195.

Of the twenty-three sanatoriums, eighteen have x-ray facilities, seven teen fluoroscopic equipment, nineteen laboratory departments and twenty-one pneumothorax facilities. These institutions administered 25,795 pneumothorax treatments. In addition there were 4,437 pneumothorax treatments given in the six hospitals mentioned.

Thirteen sanatoriums report outpatient departments and the state and county sanatoriums maintain fifteen diagnostic consultation clinics in their respective territories. In addition all cities of 50,000 or over are required to provide diagnostic tuberculosis clinics.

Massachusetts has recently completed a noteworthy tuberculosis survey under the ten year Chadwick plan (1924-1934). More than 400,000 school children were tuberculin tested, 103,000 received a roentgen examination and 117,000 were given a physical examination. Arrangements have been made to continue the survey of school children.

The tuberculosis institutions in Massachusetts have a replacement valuation of approximately \$19,099,201.56. Their annual maintenance expenditure is \$5,296,884.85. The sanatoriums are valued at \$14,640,324.81 and expend annually about \$3,623,509.61.

MICHIGAN

Michigan had 1,909 deaths from pulmonary tuberculosis in 1934 and 2,199 deaths from all forms. The tuberculosis death rate was 66.7 in 1934 and 43.2 in 1934. New cases of tuberculosis reported in 1934 total 3,575.

There are 4,991 beds for tuberculosis, 3,355 sanatorium beds, 20 beds in a separate preventorium and 1,616 beds in tuberculosis departments of other hospitals. The sanatoriums, twenty-three in all, include two state, eleven county, two municipal and eight private institutions.

The state sanatoriums have 866 beds, the county 809, the municipal 980 and the private 700. Eleven general hospitals report 383 beds for tuberculosis, nine mental institutions 224, one penal institution 90, an ear, nose and throat hospital 58 and three tuberculosis and isolation hospitals 861.

During the twelve months period covered by this report there were 5,914 patients admitted, 8,890 treated and 5,084 discharged. The average daily census of patients was 3,927 and there were 4,273 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 2,735 patients and the tuberculosis departments 3,179.

Nearly all the sanatoriums have x-ray, fluoroscopic laboratory and pneumothorax facilities and thirteen reported an outpatient clinic service. The sanatoriums administered 38,629 pneumothorax treatments and six tuberculosis departments gave 16,898.

The tuberculosis institutions in Michigan have a replacement valuation of approximately \$18,065,158.94. Their annual maintenance expenditure is \$3,508,299.47. The sanatoriums are valued at \$10,742,513.77 and expend annually about \$2,023,979.31.

MINNESOTA

Reports from the state department of health show that Minnesota had 796 deaths from pulmonary tuberculosis in 1934 and 921 deaths from all forms. The tuberculosis death rate was 69.49 in 1934 and 30.4 in 1934. New cases of tuberculosis reported in 1934 total 3,575.

Minnesota has 2,885 beds for the treatment of tuberculosis, 1,960 sanatorium beds, 80 beds in a separate preventorium and 845 beds in tuberculosis departments of other hospitals. There are sixteen sanatoriums, one state, thirteen county and two private.

The state sanatorium has 390 beds, the county sanatoriums have 1,494 and the private sanatoriums seventy-six. There are 364 beds for tuberculosis in ten general hospitals, 262 in six mental hospitals and nineteen in two penal institutions. A county preventorium has eighty beds.

During the twelve months period covered by this report there were 6,626 patients admitted, 4,535 treated and 2,177 discharged. The average daily census of patients was 2,266 and there were 2,569 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 1,454 patients, the tuberculosis departments 1,141 and the preventorium 31.

All the sanatoriums have x-ray, fluoroscopic laboratory and pneumothorax facilities except the private sanatorium for rehabilitation and

two county sanatoriums that lack fluoroscopic equipment. The sanatoriums administered 14,152 pneumothorax treatments, and five other hospitals reported 3,184.

Nine sanatoriums report outpatient departments, but practically all carry on tuberculosis clinics and school surveys in their respective districts.

The tuberculosis facilities in Minnesota have a replacement valuation of approximately \$10,507,788.08. The annual maintenance expenditure for tuberculosis is approximately \$2,510,550.72. The sanatoriums are valued at \$6,988,618 and expend annually about \$1,435,865.05.

The United States Department of the Interior has recently constructed a new sanatorium for Indians as an annex to the Minnesota State Sanatorium.

MISSISSIPPI

Mississippi has 772 beds for tuberculosis, 527 sanatorium beds and 245 in tuberculosis departments of other hospitals. There are two sanatoriums, one state and one private, with 480 and 47 beds respectively.

A federal hospital for Indians has four beds for tuberculosis and two state institutions for mental diseases have 241.

During the twelve months period covered by this report there were 401 tuberculosis patients admitted, 718 treated and 373 discharged. The average daily census of patients was 340 and there were 586 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 395 patients and the tuberculosis departments six.

The tuberculosis facilities in Mississippi have a replacement valuation of approximately \$3,014,507.67. The sanatoriums are valued at \$2,080,000 and expend annually about \$279,550.00.

MISSOURI

Reports from the state board of health and the state tuberculosis association show that Missouri had 2,248 deaths from tuberculosis in 1934 and a tuberculosis death rate of 61.56 per hundred thousand. New cases of tuberculosis reported in 1934 total 2,751.

Missouri has 2,050 beds for tuberculosis, 1,412 sanatorium beds, 85 beds in a separate preventorium and 553 beds in tuberculosis departments of other hospitals. There are seven sanatoriums, one state, two county, two municipal and two private.

The state sanatorium has 405 beds, the county sanatoriums have 118, the municipal 668 and the private 221. Tuberculosis facilities are available in two Veterans hospitals, a United States Marine Hospital and a mental hospital operated by the United States Department of Justice. Five mental institutions, four state and one municipal, have 264 beds for tuberculosis, two tuberculosis and isolation hospitals have 76 and other hospitals report 126. A preventorium under private management has eighty-five beds.

All but one sanatorium have x-ray, fluoroscopic and laboratory equipment. Six reported facilities for pneumothorax and a total of 12,984 treatments.

During the twelve months period covered by this report there were 3,461 patients admitted, 1,398 in the sanatoriums, 1,913 in the tuberculosis departments and 150 in the preventorium. The sanatoriums averaged 1,274 patients per day and there were 1,917 patients present in all tuberculosis institutions on the day of reporting.

The tuberculosis facilities in Missouri have a replacement valuation of approximately \$6,055,189.58. The annual cost of tuberculosis hospitalization is approximately \$1,379,664.51. The sanatoriums are valued at \$3,775,277.28 and expend annually about \$799,799.76.

MONTANA

Montana has one sanatorium, a state institution of 150 beds, including thirty for children. Four Indian hospitals have sixty beds for tuberculosis, a Veterans hospital has forty and there are ten in a tuberculosis and isolation hospital operated under city and county control.

The sanatorium admitted 196 patients and the tuberculosis department 126. The federal hospitals admitted 109.

The state sanatorium has a full time medical staff and is equipped for x-ray, fluoroscopic laboratory and pneumothorax procedures. It reported a total of 1,050 pneumothorax treatments.

Provisional reports of the United States Census Bureau indicate that the 1933 tuberculosis mortality rate in Montana was 45.9 per hundred thousand and from pulmonary tuberculosis and 52.5 from all forms.

The tuberculosis facilities in Montana have a replacement valuation of approximately \$697,392.87. The state sanatorium is valued at \$277,818 and expends annually about \$98,070.30.

NEBRASKA

Reports from the state department of health indicate that Nebraska had 260 deaths from pulmonary tuberculosis in 1933 and 303 deaths from all forms. The tuberculosis death rate was 32.3 in 1933 and 21.7 in 1933.

Nebraska has 307 beds for tuberculosis, 160 sanatorium beds and 147 in tuberculosis departments of other hospitals. There is a state sanatorium which has 127 beds for adults and thirty for children. A county hospital maintains a tuberculosis department of ninety beds and there are facilities for tuberculosis in four general hospitals. Two federal hospitals have forty beds for tuberculosis and six beds are available in a penal institution.

The sanatorium has a full time medical staff and is equipped with x-ray, fluoroscopic laboratory and pneumothorax facilities.

During the twelve months period covered by this report there were 388 patients admitted, 557 treated and 297 discharged. The average daily census of patients was 247 and there were 278 patients present in all tuberculosis institutions on the day of reporting. The sanatorium admitted 159 patients and the tuberculosis departments 229.

The tuberculosis facilities in Nebraska have a replacement valuation of approximately \$960,201.31. The state sanatorium is valued at \$400,000 and expends annually about \$63,131.10.

NEVADA

The Nevada State Board of Health reports approximately 200 known cases of tuberculosis in the state. In 1934 there were seventy-five deaths from pulmonary tuberculosis and eighty-four from all forms. The tuberculosis death rate in 1933 was 94.6 per hundred thousand on the basis of United States Census reports.

Tuberculous patients are admitted in three general county hospitals and in one hospital of the Indian Administration. Two of the county hospitals reported eighteen beds for tuberculosis, seven patients admitted and all three had ten tuberculous patients under treatment at the time of reporting.

NEW HAMPSHIRE

New Hampshire has 230 beds for tuberculosis, 210 sanatorium beds and twenty in tuberculosis departments of other hospitals. There are two sanatoriums, one state and one private, with a capacity of 110 and 100 beds respectively.

Tuberculous patients are also admitted in two general hospitals and one mental institution.

During the twelve months period covered by this report there were 153 patients admitted, 315 treated and 141 discharged. The average daily census of patients was 176 and there were 196 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 137 patients and the tuberculosis departments sixteen.

Provisional reports of the United States Census Bureau indicate that in 1933 the mortality rate from tuberculosis in New Hampshire was 38.0 per hundred thousand.

The tuberculosis institutions in New Hampshire have a replacement valuation of approximately \$1,026,286.34. Their annual maintenance expenditure is \$173,518.66. The sanatoriums are valued at \$950,000 and expend annually about \$152,973.66.

NEW JERSEY

Reports from the state board of health and the state tuberculosis association indicate that New Jersey had 2,038 deaths from pulmonary tuberculosis in 1934 and 2,230 deaths from all forms. The tuberculosis death rate was 90.14 in 1923 and 54.97 in 1933. New cases of tuberculosis reported in 1934 total 4,103.

New Jersey has 3,595 beds for tuberculosis, 2,468 sanatorium beds, 247 beds in a separate preventorium and 880 in tuberculosis departments of other hospitals. There are sixteen sanatoriums, one state, nine county and six private.

The state sanatorium has 420 beds, the county sanatoriums have 1,817 and the private sanatoriums 231. In addition, there are 397 beds in five tuberculosis and isolation hospitals, 338 in four mental institutions, 133 in eight general hospitals and twelve in two penal institutions. There is one preventorium aside from the sanatorium units for children.

During the twelve months period covered by this report there were 4,793 tuberculous patients admitted, 7,098 treated and 4,240 discharged. The average daily census of patients was 2,841 and there were 3,270 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 3,040 patients, the tuberculosis departments 1,133 and the preventorium 620.

Twelve sanatoriums have x-ray and fluoroscopic equipment, eleven have laboratory departments and thirteen have pneumothorax facilities. A total of 36,087 pneumothorax treatments was reported by the sanatoriums and 5,989 by other hospitals.

Tuberculosis clinics are maintained in all parts of the state under the supervision of the state and county sanatoriums, health departments and other agencies.

The tuberculosis institutions of New Jersey have a replacement valuation of approximately \$18,512,088.77. Their annual maintenance expenditure is \$3,111,003.17. The sanatoriums are valued at \$14,880,509.60 and expend annually about \$2,217,783.07.

NEW MEXICO

A report from the state bureau of public health indicates that New Mexico had 475 deaths from pulmonary tuberculosis in 1933 and 511 deaths from all forms. The tuberculosis death rate was 191.3 in 1929 and 122.6 in 1933. New cases of tuberculosis reported in 1933 total 670. These figures do not include Indians.

New Mexico has 1,553 beds for tuberculosis, 870 sanatorium beds and 683 in tuberculosis departments of other hospitals. There are eight sanatoriums in the state, one operated by the United States Public Health Service, two by the Indian Administration and five by private agencies. The federal sanatoriums have 430 beds and the private sanatoriums 440. Fourteen general hospitals have 667 beds for tuberculosis. These include two Veterans hospitals (426 beds), six Indian hospitals and six private institutions.

During the twelve months period covered by this report there were 1,508 patients admitted, 664 in the sanatoriums and 844 in the tuberculosis departments. The federal sanatoriums and departments admitted 533. The average daily census of patients was 857 and there were 958 patients present in all tuberculosis institutions on the day of reporting.

The tuberculosis facilities in New Mexico have a replacement valuation of approximately \$4,700,828.26. The annual maintenance cost is approximately \$1,219,158.98. The sanatoriums are valued at \$2,116,589.21 and expend annually about \$550,051.01.

NEW YORK

New York has 14,582 beds for tuberculosis, 9,650 sanatorium beds, 252 beds in separate preventoriums and 4,680 in tuberculosis departments of other hospitals. There are sixty sanatoriums in the state, two federal, four state, twenty-eight county, five municipal, one city and county and twenty private.

The federal sanatoriums have 999 beds, the state 300, the county 3,075, the municipal 2,509, the city and county 135 and the private 2,632.

(Three new state sanatoriums were not in operation at the time of the survey.)

Other institutions that have tuberculosis departments include thirty-six general hospitals (2,031 beds), four orthopedic (sixty beds), three tuberculosis and isolation hospitals (490 beds), twenty-six mental institutions (1,712 beds), four penal institutions (201 beds), two chronic hospitals (164 beds), and one convalescent hospital (twenty-two beds).

These departments represent seven federal hospitals, twenty-eight state institutions, four county hospitals, one city and county hospital, fourteen municipal institutions and twenty-two private hospitals.

Reports from the state department of health and the New York City Health Department indicate that New York had 6,849 deaths from pulmonary tuberculosis in 1934 (3,950 in New York City) and 7,575 deaths from all forms (4,420 in New York City). The tuberculosis death rate in 1934 was 52.5 in upstate New York and 59.1 in New York City. New cases of tuberculosis reported in 1934 total 16,902 (10,722 in New York City).

During the twelve months period covered by this report there were 24,331 patients admitted, 32,960 treated and 20,639 discharged. The average daily census of patients was 11,850 and there were 13,249 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 11,631 patients, the tuberculosis departments 11,854 and four preventoriums 846.

Of the sixty sanatoriums, fifty-one have x-ray equipment, fifty fluoroscopic facilities, forty-six laboratory departments and fifty-two pneumothorax facilities. A total of 73,462 pneumothorax treatments was reported by the sanatoriums and 30,956 by other hospitals.

Twenty-seven sanatoriums maintain outpatient departments. There are sixty-nine permanent tuberculosis clinics in the state of New York according to the report of the state department of health. In addition, fourteen county tuberculosis hospitals conduct clinics in their respective districts and the state department of health maintains an itinerant clinic service in twenty-six rural counties. The state department held 152 clinics in 1934 and made 6,177 examinations. In fifty-nine upstate clinics there were 44,477 examinations. In all 84,343 examinations were made by the state department of health, the municipal and county tuberculosis hospitals and local dispensaries. The Department of Health of New York City reported 54,601 patients treated in the tuberculosis clinics in 1934 and a total of 127,357 visits.

The tuberculosis institutions in New York have a replacement valuation of approximately \$63,230,844.88. Their annual maintenance expenditure is \$13,732,149.81. The sanatoriums are valued at \$47,489,262.24 and expend annually about \$8,494,022.07.

NORTH CAROLINA

North Carolina had 1,891 deaths from pulmonary tuberculosis in 1934 and 2,092 deaths from all forms. The tuberculosis death rate was 94.7 in 1924 and 63.4 in 1934. New cases of tuberculosis reported in 1934 total 2,136.

The total number of beds for tuberculosis is 2,625, 2,452 sanatorium beds and 173 in tuberculosis departments of other hospitals. There are twenty-three sanatoriums in the state, one federal, one state, seven county and fourteen private.

The federal sanatorium has 850 beds, the state sanatoriums 484, the county sanatoriums 486 and the private sanatoriums 632.

Tuberculosis facilities are available also in five general hospitals, two mental institutions (110 beds), one orthopedic hospital and a county home.

During the twelve months period covered by this report there were 2,865 patients admitted, 4,189 treated and 2,445 discharged. The average daily census of patients was 1,841 and there were 1,889 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 2,836 patients and the tuberculosis departments twenty-nine.

Of the twenty-three sanatoriums, eleven have x-ray facilities, twelve fluoroscopic equipment, eight laboratory departments and thirteen pneumothorax facilities. Five sanatoriums maintain outpatient departments. The state sanatorium conducts a daily diagnostic clinic and examines approximately 3,000 patients annually. It was also reported that three physicians employed to conduct diagnostic clinics in various parts of the state examine annually about 3,000 adults and 25,000 school children.

The tuberculosis institutions in North Carolina have a replacement valuation of approximately \$6,062,967.65. Their annual maintenance expenditure is \$1,952,389.67. The sanatoriums are valued at \$5,403,090.81 and expend annually about \$1,774,675.42.

NORTH DAKOTA

A report from the state department of public health indicates that North Dakota had 133 deaths from pulmonary tuberculosis in 1933 and 167 deaths from all forms. The tuberculosis death rate was 41.8 in 1924 and 24.16 in 1933. New cases of tuberculosis reported in 1933 total 380.

North Dakota has 341 beds for tuberculosis, 265 sanatorium beds and seventy-six in tuberculosis departments of other hospitals. There is one sanatorium, a state-owned institution which has 215 beds for adults and fifty for children. In addition, there are eighteen beds for tuberculosis in two Indian hospitals, forty-five in two state hospitals for mental diseases and ten in a penal institution. Three private general hospitals accept tuberculous patients.

During the twelve months period covered by this report there were 300 patients admitted, 477 treated and 213 discharged. The average daily census of patients was 249 and there were 279 patients present in all tuberculosis institutions on the day of reporting. The sanatorium admitted 200 patients and the tuberculosis departments 100.

The tuberculosis facilities in North Dakota have a replacement valuation of approximately \$887,487.65. The annual cost of tuberculosis hospitalization is approximately \$234,031.34. The sanatorium is valued at \$620,000 and expends annually about \$163,041.84.

OHIO

Ohio has 4 670 beds for tuberculosis 3,214 sanatorium beds, 60 beds in a separate preventorium and 1 396 in tuberculosis departments of other hospitals There are twenty-one sanatoriums one state fourteen county one municipal one city and county and four private

The state sanatorium has 240 beds, the county sanatoriums 2 178 the municipal sanatoriums 48 the city and county sanatoriums 462 and the private sanatoriums 286

There are additional tuberculosis facilities in three federal hospitals (273 beds) thirteen state institutions a county home three general city hospitals and fifteen private institutions

Fourteen general hospitals reported 808 beds for tuberculosis and five state institutions for mental diseases reported 519 beds

Of the twenty-one sanatoriums twenty have x ray departments fluoroscopic equipment clinical laboratories and pneumothorax facilities The sanatoriums administered 30 496 pneumothorax treatments

The Ohio State Department of Health reported 3 506 deaths from all forms of tuberculosis in 1934 The tuberculosis death rate was 76.14 in 1925 and 49.96 in 1934 New cases of tuberculosis reported in 1934 total 7 010

During the twelve months period covered by this report there were 5 908 patients admitted 7,861 treated and 4 183 discharged The average daily census of patients was 3 509 and there were 4 198 patients present in all tuberculosis institutions on the day of reporting The sanatoriums admitted 3 444 patients, the tuberculosis departments 2 264 and one preventorium 200

Twelve sanatoriums maintain outpatient departments. The state department of health reported ten diagnostic chest clinics in nine counties during 1933

The tuberculosis institutions in Ohio have a replacement valuation of approximately \$17 784 715 98 Their annual maintenance expenditure is \$3 641 486 75 The sanatoriums are valued at \$12 324,801 99 and expend annually about \$2,269 524 75

OKLAHOMA

Reports from the state department of public health and the state tuberculosis association indicate that Oklahoma had 1 219 deaths from pulmonary tuberculosis in 1933 and 1 255 deaths from all forms The tuberculosis death rate was 49.2 in 1933 New cases of tuberculosis reported in 1933 total 861

Oklahoma has 1 076 beds for tuberculosis 888 sanatorium beds and 188 in tuberculosis departments of other hospitals. There are six sanatoriums in the state, two Indian three state and one private. The federal sanatoriums have 225 beds the state sanatoriums have 603 and the private sanatorium has sixty beds

Tuberculosis facilities are also available in ten general hospitals a state penal institution and three mental hospitals (100 beds)

Five sanatoriums have x ray fluoroscopic and laboratory facilities and all have pneumothorax equipment A total of 5,079 pneumothorax treatments were reported

There were 1 677 patients admitted in one year 2 258 treated and 1 141 discharged The average daily census of patients was 769 and there were 922 patients present in all tuberculosis institutions on the day of reporting The sanatoriums admitted 1 218 patients and the tuberculosis departments 459

Four sanatoriums maintain an outpatient department The Oklahoma Tuberculosis and Health Association makes school surveys in cooperation with local agencies In the past two and one-half years 70 000 tuberculin tests have been made

The tuberculosis institutions in Oklahoma have a replacement valuation of approximately \$2 994 554 95 Their annual maintenance expenditure is \$612 897 73 The sanatoriums are valued at \$2 277 463 35 and expend annually about \$419 774 73

OREGON

Oregon has 622 beds for tuberculosis 513 sanatorium beds and 109 in tuberculosis departments of other hospitals There are four sanatoriums two state one county and one private

The state sanatoriums have 409 beds the county sanatorium has thirty nine and the private sanatorium has sixty five There are additional facilities for tuberculosis in five general hospitals and three mental institutions

Reports from the state board of health and the state tuberculosis association indicate that Oregon had 289 deaths from pulmonary tuberculosis in 1934 and 349 deaths from all forms The tuberculosis death rate was 65 in 1925 and 35.7 in 1933 New cases of tuberculosis reported in 1934 total 567

During the twelve months period covered by this report there were 594 patients admitted 827 treated and 385 discharged The average daily census of patients was 468 and there were 610 patients present in all tuberculosis institutions on the day of reporting The sanatoriums admitted 462 patients and the tuberculosis departments 132

Three of the sanatoriums have x ray fluoroscopic laboratory and pneumothorax facilities They administered 3,967 pneumothorax treatments during the year

The two state sanatoriums maintain outpatient departments and there are approximately eight tuberculosis clinics throughout the state. The University of Oregon Medical School conducts three tuberculosis clinics a week in Portland

The tuberculosis institutions in Oregon have a replacement valuation of approximately \$1 243 264 13 Their annual maintenance expenditure is \$403 015 40 The sanatoriums are valued at \$827 503.58 and expend annually about \$291 043 15

PENNSYLVANIA

The Pennsylvania Tuberculosis Society reported 4 517 deaths from pulmonary tuberculosis in 1934 and 4 965 deaths from all forms The tuberculosis death rate was 86.6 in 1923 and 50.6 in 1934 New cases of tuberculosis reported in 1934 total 5 653

Pennsylvania has 6,293 beds for tuberculosis 4 189 sanatorium beds 100 beds in a separate preventorium and 2 004 beds in tuberculosis departments of other hospitals There are seventeen sanatoriums three state three county one municipal one city and county and nine private

The state sanatoriums have 2 415 beds the county sanatoriums have 337 the municipal sanatorium has 290 the city and county sanatorium has fifty seven and the private sanatoriums have 1 090 beds

Tuberculosis patients were also admitted in five federal hospitals fifteen state institutions six county institutions three municipal hospitals a city and county institution and twenty six private hospitals Seventeen mental hospitals report 1,170 beds for tuberculosis and two penal institutions have twenty two

During the twelve months period covered by this report there were 9 133 patients admitted 11 900 treated and 7 570 discharged The average daily census of patients was 4 594 and there were 5 553 patients present in all tuberculosis institutions on the day of reporting The sanatoriums admitted 5,213 patients the tuberculosis departments 3 686 and one preventorium 234

Thirteen sanatoriums have x ray equipment, fourteen have fluoroscopic apparatus fifteen have laboratory departments and sixteen have pneumothorax facilities The sanatoriums reported 20 717 pneumothorax treatments and other hospitals reported 4 020

Five of the sanatoriums report outpatient departments There are 117 tuberculosis clinics in Pennsylvania. The state department of health conducts eighty five the Philadelphia City Department of Health eleven the Pittsburgh City Department of Health three the Tuberculosis League of Pittsburgh four the Berks County Sanatorium one the Delaware County Tuberculosis Society one and the Lancaster General Hospital one and various hospitals and agencies in Philadelphia conduct eleven

The tuberculosis institutions in Pennsylvania have a replacement valuation of approximately \$25 749 730 59 Their annual maintenance expenditure is \$4 111 546 33 The sanatoriums are valued at \$17,338 585 93 and expend annually about \$2 383 463 60

RHODE ISLAND

Reports from the state board of health indicate that Rhode Island had 285 deaths from pulmonary tuberculosis in 1934 and 315 deaths from all forms The tuberculosis death rate was 88.6 in 1924 and 43.6 in 1934 New cases of tuberculosis reported in 1934 total 1 014

Rhode Island has 605 beds for tuberculosis 495 sanatorium beds sixty in tuberculosis departments of other hospitals and fifty in a separate preventorium There are two sanatoriums one state and one private

The state sanatorium has 430 beds and the private sanatorium sixty five Tuberculosis facilities are also available in one mental hospital one penal institution three general hospitals and one isolation and tuberculosis hospital (sixty beds)

During the twelve months period covered by this report there were 854 patients admitted 1,325 treated and 552 discharged The average daily census of patients was 569 and there were 620 patients present in all tuberculosis institutions on the day of reporting The sanatoriums admitted 412 patients the tuberculosis departments 191, and the preventorium 251

The state sanatorium maintains an outpatient department and there are tuberculosis clinics in every important center of population in the state

The tuberculosis institutions in Rhode Island have a replacement valuation of approximately \$1,150 350 Their annual maintenance expenditure is \$376 335 87 The sanatoriums are valued at \$900 000 and expend annually about \$277 601 22

SOUTH CAROLINA

South Carolina has 675 beds for tuberculosis 539 sanatorium beds and 136 in tuberculosis departments of other hospitals. There are six sanatoriums one state, three county one city and county and one private

The state sanatorium has 277 beds the county sanatoriums have 166 the city and county sanatorium has twenty six and the private sanatorium has seventy Provisions are made for tuberculosis in a mental institution and in five general hospitals (136 beds)

The South Carolina Tuberculosis Association reported 1 080 deaths from pulmonary tuberculosis in 1933 and 1 094 deaths from all forms The tuberculosis death rate was 91.0 in 1926 and 62.6 in 1933 New cases of tuberculosis reported in 1934 total 1 019

During the twelve months period covered by this report there were 767 patients admitted 969 treated and 505 discharged The average daily census of patients was 507 and there were 530 patients present in all tuberculosis institutions on the day of reporting The sanatoriums admitted 565 patients and the tuberculosis departments 202

Permanent tuberculosis clinics are maintained at the state sanatorium and in seven counties

The tuberculosis facilities in South Carolina have a replacement valuation of approximately \$923,812 31 The annual maintenance expenditure is approximately \$285 868 96 The sanatoriums are valued at \$684 704 81 and expend annually about \$232 213 18

SOUTH DAKOTA

South Dakota has 297 beds for tuberculosis 192 in the state sanatorium and 105 in four general hospitals

The state tuberculosis association reported 249 deaths from all forms of tuberculosis in 1934 The tuberculosis death rate was 40.42 in 1933 and 35.31 in 1934 New cases of tuberculosis reported in 1934 total 180

During the twelve months period covered by this report there were 343 patients admitted and 540 treated. The average daily census of patients was 203 and there were 266 patients present in all tuberculosis institutions on the day of reporting. The sanatorium admitted 101 patients and the tuberculosis departments 242.

The tuberculosis facilities in South Dakota have a replacement valuation of approximately \$1,150,503.29. The annual maintenance expenditure is approximately \$241,854.95. The sanatorium is valued at \$750,000 and expends annually about \$133,993.70.

TENNESSEE

Tennessee has 1,572 beds for tuberculosis: 1,124 sanatorium beds, 398 in tuberculosis departments of other hospitals and fifty in a separate preventorium. There are seven sanatoriums in the state: one county, two city and county and four private.

The county sanatorium has 300 beds; the city and county sanatoriums have 503 and the private sanatoriums have 521.

Five general hospitals report seventy-nine beds for tuberculosis: three mental institutions, 229 beds and one penal institution, ninety beds.

A report from the state department of health indicates that Tennessee had 2,291 deaths from pulmonary tuberculosis in 1933 and 2,589 deaths from all forms. The tuberculosis death rate was 95.7 in 1933. New cases of tuberculosis reported in 1933 total 2,269.

During the twelve months period covered by this report there were 1,208 patients admitted, 1,943 treated and 995 discharged. The average daily census of patients was 891 and there were 1,209 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 979 patients, the tuberculosis departments 197 and the preventorium 32.

Four sanatoriums maintain outpatient departments and the state department of health conducts periodic clinics in all counties having a full-time health service. Special tuberculosis studies have been made in three representative counties of the state. Approximately 50,000 persons were examined in the tuberculosis clinics from 1927 to 1934 inclusive.

Six sanatoriums have x-ray fluoroscopic and laboratory facilities and all have pneumothorax equipment. They reported a total of 5,335 pneumothorax treatments during a one-year period.

The tuberculosis institutions in Tennessee have a replacement valuation of approximately \$3,803,098.17. Their annual maintenance expenditure is \$889,385.97. The sanatoriums are valued at \$2,245,000 and expend annually about \$469,307.47.

TEXAS

A report from the state department of health indicates that Texas had 3,391 deaths from pulmonary tuberculosis in 1934 and 3,772 deaths from all forms. The tuberculosis death rate was 71.4 in 1933. New cases of tuberculosis reported in 1934 total 3,036.

Texas has 2,865 beds for the treatment of tuberculosis: 1,971 sanatorium beds and 894 in tuberculosis departments of other hospitals. There are seventeen sanatoriums: one state, two county, three city and county and eleven private.

The state sanatorium has 718 beds; the county sanatoriums have 102; the city and county sanatoriums have 342 and the private sanatoriums have 809.

Fifteen general hospitals report 586 beds for tuberculosis: seven mental institutions, 232 beds; one penal institution, four beds; and one county home, seventy-two beds.

During the twelve months period covered by this report there were 4,679 patients admitted, 3,685 in the sanatoriums and 994 in the tuberculosis departments. The sanatoriums treated 4,712 patients, discharged 3,389 and maintained an average daily census of 1,599. There were 2,341 patients present in all tuberculosis institutions on the day of reporting.

Two of the sanatoriums report outpatient departments. Ten have x-ray facilities; thirteen have fluoroscopic equipment; thirteen maintain laboratory departments and sixteen have pneumothorax facilities. The sanatoriums reported 7,569 pneumothorax treatments during a twelve-month period.

The tuberculosis institutions in Texas have a replacement valuation of approximately \$8,049,766.70. Their annual maintenance expenditure is \$1,810,081.19. The sanatoriums are valued at \$4,636,829.75 and expend annually about \$946,653.41.

UTAH

Reports from the state board of health and the state tuberculosis association indicate that Utah had eighty-six deaths from pulmonary tuberculosis in 1934 and ninety-three deaths from all forms. The tuberculosis death rate was 39.1 in 1920 and 18.3 in 1934. New cases of tuberculosis reported in 1934 total 141.

Utah has no sanatoriums but has fifty-four beds for tuberculosis in five general hospitals.

The tuberculosis departments admitted 126 patients during the twelve-month period covered by this report. The average daily census of patients was twenty-five and there were fifty patients present on the day of reporting.

The state department of health and the state tuberculosis association conduct tuberculosis clinics in various parts of the state.

VERMONT

A report from the state board of health shows that Vermont had 156 deaths from pulmonary tuberculosis in 1934 and 188 deaths from all forms. The tuberculosis death rate was 78 in 1924 and 52 in 1934. New cases of tuberculosis reported in 1934 total 113.

Vermont has 171 beds for tuberculosis: 127 in two state sanatoriums and forty-four in a separate preventorium.

During the twelve-month period covered by this report there were 247 patients admitted, 368 treated and 210 discharged. The average daily census of patients was 157 and there were 161 patients present on the day of reporting. The sanatoriums admitted 137 patients and the preventorium eighty-three. A private general hospital admitted twenty-seven.

The tuberculosis institutions in Vermont have a replacement valuation of approximately \$730,000. Their annual maintenance expenditure is \$122,472.11. The sanatoriums are valued at \$650,000 and expend annually about \$94,137.20.

VIRGINIA

A report from the state board of health indicates that Virginia had 1,744 deaths from pulmonary tuberculosis in 1934 and 2,034 deaths from all forms in 1933. The tuberculosis death rate was 114.6 in 1925 and 83.3 in 1933. New cases of tuberculosis reported in 1934 total 3,876.

Virginia has 1,425 beds for tuberculosis: 1,123 sanatorium beds and 302 in tuberculosis departments of other hospitals. There are seven sanatoriums: three state, two municipal and two private.

The state sanatoriums have 760 beds; the municipal 278 and the private eighty-five. Tuberculosis facilities are also available in four general hospitals, four mental institutions, a city home and one penal institution.

During a twelve-month period there were 1,668 patients admitted, 1,361 in the sanatoriums and 307 in the tuberculosis departments. The sanatoriums treated 2,346, discharged 1,292 and maintained an average daily census of 985. There were 1,229 patients present in all tuberculosis institutions on the day of reporting.

In 1933 the state conducted tuberculosis clinics in eleven cities and eighty-seven counties. There were a total of 8,364 examinations and 1,664 x-ray studies.

The tuberculosis institutions in Virginia have a replacement valuation of approximately \$3,734,627.10. Their annual maintenance expenditure is \$855,274.18. The sanatoriums are valued at \$2,773,047.85 and expend annually about \$581,181.68.

WASHINGTON

Reports from the state board of health and the state tuberculosis association indicate that Washington had 744 deaths from pulmonary tuberculosis in 1933 and 857 deaths from all forms. The tuberculosis death rate was 76.7 in 1923 and 53.6 in 1933. New cases of tuberculosis reported in 1934 total 1,544.

The state of Washington has 1,531 beds for tuberculosis: 51 sanatorium beds and 780 in tuberculosis departments of other hospitals. There are nine sanatoriums in the state: one Indian, five county and three private.

The federal sanatorium has forty beds; the county sanatoriums have 575 and the private sanatoriums have 136. In addition, the Firland Sanatorium and Isolation Hospital has 250 beds; two Veterans hospitals have 174 beds for tuberculosis; two hospitals of the United States Public Health Service have 61 and an Indian hospital for general cases and tuberculosis has 268. There are twenty-seven beds for tuberculosis in a state hospital for mental diseases. Eight private hospitals reported the admission of tuberculous patients.

During a twelve-month period there were 1,477 patients admitted, 2,316 treated and 1,235 discharged. The average daily census of patients was 1,183 and there were 1,284 patients present in all tuberculosis institutions on the day of reporting. The sanatoriums admitted 786 patients and the tuberculosis departments 691.

Four sanatoriums report outpatient departments and there are tuberculosis clinics in various parts of the state conducted by the sanatorium staffs, tuberculosis association and local health authorities.

The tuberculosis institutions in Washington have a replacement valuation of approximately \$4,034,445.65. Their annual maintenance expenditure is \$1,145,685.14. The sanatoriums are valued at \$1,776,027.23 and expend annually about \$478,838.61.

One new sanatorium has been opened since the survey was completed, namely the Blue Mountain Sanatorium, Walla Walla, a county institution of thirty-six beds.

WEST VIRGINIA

A report from the state department of health shows that West Virginia had 932 deaths from tuberculosis in 1933. The tuberculosis death rate was 77.7 in 1926 and 52.7 in 1933. There were 1,395 new cases of tuberculosis reported last year.

West Virginia has 849 beds for tuberculosis: 772 sanatorium beds and seventy-seven in tuberculosis departments of other hospitals. There are seven sanatoriums: three state, two county and two private.

The state sanatoriums have 648 beds; the county forty-nine and the private sanatoriums seventy-five. There are additional tuberculosis facilities in a general Veterans hospital, three state institutions for mental diseases, a state penal institution and two private general hospitals.

During a twelve-month period there were 930 patients admitted, 1,971 in the sanatoriums and 133 in the tuberculosis departments. The sanatoriums treated 1,441 patients, discharged 766 and maintained an average daily census of 692. There were 802 patients present in all tuberculosis institutions on the day of reporting.

Two of the sanatoriums report outpatient departments and there are additional tuberculosis clinics conducted by the state tuberculosis association.

The tuberculosis institutions in West Virginia have a replacement valuation of approximately \$2,358,202.41. Their annual maintenance expenditure is \$441,690.20. The sanatoriums are valued at \$2,064,500 and expend annually about \$362,591.95.

WISCONSIN

Reports from the state board of health and the state tuberculosis association indicate that Wisconsin had 1,006 deaths from pulmonary tuberculosis in 1934 and 1,117 deaths from all forms. The tuberculosis death rate was 66.5 in 1923 and 36.5 in 1934. New cases of tuberculosis reported in 1934 total 1,753.

Wisconsin has 2,497 beds for tuberculosis: 1,989 sanatorium beds and 508 in tuberculosis departments of other hospitals and 116 in a separate preventorium. There are twenty-one sanatoriums: two state, seventeen county and two private.

The state sanatoriums have 282 beds; the county 1,610 and the private ninety-seven. A Veterans hospital has 254 beds for tuberculosis and three

Indian hospitals have thirty seven. Provisions have also been made for tuberculous patients in five state institutions six county institutions and five private hospitals.

During the twelve months period covered by this report there were 2730 patients admitted 1949 in the sanatoriums 684 in the tuberculosis departments and ninety seven in the preventorium. The sanatoriums treated 3557 discharged 1744 and maintained an average daily census of 1843. There were 2198 patients present in all tuberculosis institutions on the day of reporting.

Seventeen of the sanatoriums have x-ray fluoroscopic and laboratory equipment and twenty have pneumothorax facilities. A total of 11991 pneumothorax treatments was administered during the year.

Seven of the sanatoriums report outpatient departments. In addition there are tuberculosis clinics conducted by the Wisconsin Anti Tuberculosis Association local health departments and county medical societies. In 1933 there were 275 clinics held in fifty four communities.

The tuberculosis institutions in Wisconsin have a replacement valuation of approximately \$8,237,947.56. Their annual maintenance expenditure is \$1,923,595.94. The sanatoriums are valued at \$6,509,923.30 and expend annually about \$1,469,293.94.

WYOMING

Wyoming has sixty five beds for tuberculosis thirty three in a state sanatorium and thirty two in tuberculosis departments of other hospitals. A Veterans Administration Hospital for mental diseases has fifteen beds for tuberculosis and a general Indian hospital has seventeen. Some provision has also been made for tuberculosis in the state hospital for mental diseases and in a private general hospital.

The sanatorium has a full time medical director. It is equipped for x-ray fluoroscopic and laboratory examinations and for pneumothorax therapy. The sanatorium maintains an outpatient department, and the medical director conducts tuberculosis clinics throughout the state in cooperation with the state tuberculosis association and local health agencies.

During the annual period covered by this report there were fifty nine patients admitted for tuberculosis thirty-one in the sanatorium and twenty-eight in the tuberculosis departments. The sanatorium treated forty six patients and maintained a daily average of twenty eight. The state board of health reported a tuberculosis death rate of 30.3 per hundred thousand in 1933.

The state sanatorium has a valuation of \$200,588.93 and its maintenance expenditure is approximately \$32,000 a year.

TUBERCULOSIS HOSPITALS AND SANATORIUMS, DEPARTMENTS AND PREVENTORIUMS

The following list contains the names and statistics concerning

471 hospitals and sanatoriums Page 1899

740 tuberculosis department of hospitals Page 1909

29 institutions classified as preventoriums Page 1915

The statistics were obtained by inspection and by questionnaires returned during the year 1934 for the twelve months next preceding the date of questionnaire.

SATURDAY, DECEMBER 7, 1935

THE TUBERCULOSIS SURVEY

In this issue, THE JOURNAL presents a unique report of a survey of tuberculosis hospitals, sanatoriums, tuberculosis departments and preventoriums, which provides the most complete data yet obtained on the hospitalization of tuberculous patients in the United States. The report is a compilation of facts which lend themselves to comparative studies.

The purpose of the survey made by the Council on Medical Education and Hospitals was to give the medical profession a comprehensive picture of tuberculosis hospitalization in this country. The report will also assist in the registration of hospitals and sanatoriums and in their recognition for purposes of training physicians and nurses. It covers 471 tuberculosis hospitals and sanatoriums, 740 tuberculosis departments of hospitals and twenty-nine institutions classified as preventoriums, a total of 1,240 institutions.

The great number of classified facts presented in these pages was made possible by the cooperation of many persons and agencies, including the officers of the American Sanatorium Association and the National Tuberculosis Association, who assisted in the preparation of questionnaires and the direction of the survey and the officers of the institutions, 98.9 per cent of whom filled out and returned the questionnaire and who responded cordially to each of the 656 visits of inspection by the hospital examiners on the staff of the Council on Medical Education and Hospitals. Nearly all state departments of health and state tuberculosis associations contributed data from their offices not available elsewhere.

The survey shows that 95,198 beds are available for tuberculous patients throughout the states and there is an average of 69,024 patients. Construction planned or in progress will add another 6,661 beds.

The figures given were obtained within the calendar year 1934 and are for the twelve months preceding the date of the questionnaire. During that time 97,381 patients were discharged, including those who died. Reports of state departments of health and estimates based on the United States Census indicate that the

total deaths, institutional and otherwise, from all forms of tuberculosis in the year 1933 were 74,564. Among those treated for tuberculosis in institutions, 67,021 were adults. Of these cases 75 per cent were reported as "arrested," 9.8 per cent as "apparently arrested," 11.6 per cent as "quiescent," 30 per cent "improved," 17.2 per cent "unimproved," and 23.9 per cent of the patients died.

The ratio of physicians to patients is 1:28 in the Veterans tuberculosis hospitals, 1:52 in the Indian sanatoriums and 1:36 in the tuberculosis hospital operated by the U. S. Public Health Service, 1:62 in the state institutions, 1:51 in the county, 1:70 in the municipal, 1:60 in the city and county, and 1:32 in the private sanatoriums.

The total cost of all the facilities provided for tuberculosis in all institutions including the value of land, buildings and equipment and figured on the basis of replacement is around \$330,000,000. The average cost of these facilities in veterans' hospitals was \$4,000 per bed.

In most of the other institutions, both private and public, the cost per bed was less, but there are extremes in variation. In several instances, because of elaborate plans and expensive equipment, the cost of existing institutions has been as high as \$10,000 per bed, and one sanatorium built with public money cost \$13,043 per bed.

In hospitals maintaining tuberculosis departments, 225 provided separate buildings, 304 had segregated units and 211 failed to show what provision was made for segregation from nontuberculous patients. In tuberculosis sanatoriums the need for isolation facilities is attested by the admission of 12,629 children, 1,191 of whom had adult type tuberculosis, 6,659 the childhood type, 824 had extrapulmonary lesions, 3,236 were non-tuberculous and 701 were unclassified.

Four tuberculosis departments and 120 sanatoriums have separate buildings for children. In a few sanatoriums it was found that adults and children are allowed to associate in various ways. In a few cases children with pulmonary cases were hospitalized with children in the preventorium unit. Such conditions call for prompt corrective action.

The use of tuberculosis departments in general hospitals has been endorsed by the American Medical Association, the American Hospital Association and the National Tuberculosis Association. The endorsement, however, embodies a requirement of adequate segregation for the protection of other patients and personnel. In the crusade against tuberculosis, all institutions should keep pace with the advancing standards. There is need for increasing vigilance on the part of both specialists and general practitioners.

An attempt was not made at a relative rating of the individual institutions, but comment that would characterize the tuberculosis institutions of the United States in general would in most cases be commendatory.

GROWTH OF LONG BONES

The first observations on the growth of long bones were made by Stephen Hales,¹ whose extraordinary versatility in the field of science has generally been overshadowed by the emphasis placed on his discourses on the circulation. Among the numerous contributions of this clergyman and scientist is recorded an experiment performed in 1747 in which Hales drilled two holes in the shaft of the tibia of a chicken. Two months later the bone was examined and, although the shaft had increased an inch in length, the distance between the holes had remained the same. Hales observed that most of the lengthening of the bone had occurred at the proximal end and concluded that growth in the length of long bones results entirely from deposition of new bone at the extremities, the amount of the growth from the two ends was unequal. A little more than a century later, Ollier² reported the first clinical evidence of unequal growth from the two ends of long bones. He reported that when the knee joint had been resected the leg was considerably shorter than normal on reaching maturity, removal of the elbow joint under similar conditions produced little shortening of the arm.

Since these two early observations there have been many experimental and clinical reports describing the growth of long bones. However, the problem of measuring accurately the quantity of growth that takes place from each end of the principal long bones is a more difficult one. Methods and measurements have been devised and recorded, but well controlled actual measurements have been lacking. The recent detailed study by the Bisgards,³ however, leaves little to be desired in detail and accuracy of direct measurements of the longitudinal growth of long bones. These authors worked with new-born goats and thus obtained records of the entire postnatal period of growth. When the animals were from 2 to 5 days old, the bones were marked with steel shots placed in drill holes in the shafts. Roentgenograms were taken of the bones at the beginning and the end of the experiments and at intervals during the course of investigations extending over a twelve to eighteen months period, the span of major growth. Final measurements from which growth calculations were obtained by actual measurement of postmortem examinations. It was possible to determine the proportion of growth that takes place at each end of each principal long bone by placing the shots at a measured distance from the epiphyseal cartilages at the ends of the shaft. The periodic roentgenograms gave the serial representation of growth in the postmortem specimens the shots were exposed and exact measurements made of the distance between the shot and the end of each diaphysis. The differences between these measurements and those recorded at the

beginning of the experiment represented the distance that the epiphyseal lines had moved during growth away from the shots, which remained as fixed points to mark the original locations of the epiphyseal lines. It was observed that the lengthening of long bones, which occurs at the ends, takes place by the deposition of layers of new bone between the end of the diaphysis and the epiphyseal cartilage and between the articular cartilage and the epiphysis. The proportion of longitudinal growth from the two ends of a long bone was found to be unequal. The rate of growth remains constant during the first two months and then progresses at half its former rate. The epiphyseal cartilage, giving the lesser increment of growth, is the first to ossify and close.

These investigations of the postnatal growth of long bones are supplemented by similar studies of prenatal growth. In order to conduct the latter experiments, the Bisgards devised a method for marking the embryonic bones as soon after the beginning of ossification as possible. This was accomplished by producing phosphorus arrest lines in the bones of the fetus by feeding phosphorus to the mothers. The results of these experiments demonstrated that prenatal as well as postnatal longitudinal growth of the long bones takes place at the ends but that growth from the two ends is proportionately more equal before than after birth, particularly during the first portion of prenatal life.

THE IRON REQUIREMENT OF MAN

The necessity of iron for the formation of hemoglobin attaches considerable importance to the question of the amount of this element needed to satisfy the daily human requirement. Attempts to ascertain this value accurately were made more than thirty years ago by the use of the balance method, which involves the simultaneous daily determination of the amount of iron ingested in the food and the amount excreted in the feces and urine. When the quantity of iron ingested just equals the quantity excreted, the subject is said to be in "iron equilibrium", obviously, in the adult, such a state is a satisfactory one from a nutritional point of view and indicates that the diet employed contains a sufficient amount of the element in question. Moreover, the amount of iron that just suffices to maintain the subject in equilibrium represents the daily "iron requirement". If, however, the amount excreted exceeds the amount ingested, it is obvious that the diet does not contain sufficient iron to satisfy the requirement, and if the regimen should be continued a severe anemia may result. Such a situation is not uncommon in persons consuming a restricted type of diet.

Several early iron balance studies on man¹ demonstrated that equilibrium can be maintained in normal adult male subjects by diets providing as little as 10 mg of iron daily. In order to allow a margin of safety

for possible poor absorption or impaired utilization, the value of 15 mg a day was suggested as a satisfactory standard. Recently the problem has been reinvestigated in a somewhat more satisfactory manner, longer experimental periods being employed.² Two normal men were maintained on a diet of low iron content for 316 and 260 days respectively. During the latter part of the period the iron content of the daily food and excreta was determined quantitatively. The daily iron intake for one subject averaged 5.2 mg, the average daily excretion was about the same, 5.2 mg appearing in the feces and 0.02 mg in the urine. The other subject remained in equilibrium on a diet containing 7.8 mg of iron daily. The iron and hemoglobin content of the blood and the erythrocyte counts of these subjects remained within normal limits during the entire period of observation. Thus it appears that the actual daily iron requirement of the normal adult male is no greater than 5 mg. A similar recent study³ on two persons indicates that the requirement of the normal, nonpregnant adult female does not differ greatly from that of the male. However, it is possible that the amount may be slightly greater, for at least 12 mg of iron in the form of hemoglobin is lost during each menstrual period.²

Because of the added nutritional stress imposed by such factors as growth, pregnancy and lactation, it is reasonable to expect that a relatively larger amount of iron would be necessary to maintain a state of equilibrium in these conditions than in the normal adult. Indeed, studies on growing and pregnant subjects support this view. It has been demonstrated repeatedly⁴ that satisfactory equilibrium can be maintained in young children by diets providing 0.6 mg of iron per kilogram of body weight. During pregnancy, a daily iron intake of from 15 to 20 mg insures a satisfactory iron balance.⁵ Of this amount, from 2 to 6 mg daily is used to supply the demand of the growing fetus.

One point of considerable importance that has not been taken into consideration in iron balance studies is the proportion of the total iron ingested that is available for the formation of hemoglobin. If the food iron were in a form that could not be absorbed from the intestine, it obviously would appear in the feces and an apparent iron equilibrium would be maintained while in reality the subject would be experiencing iron "starvation" just as though this element were lacking in the diet. Both chemical and biologic studies⁶ have demon-

strated that the availability of iron for physiologic purposes varies widely in different foods. Less than one fourth of the iron present in oysters, spinach, alfalfa and blood is available for hemoglobin formation, whereas more than half of that present in beef muscle, liver, wheat, yeast, soy beans and oats is utilizable. The fact that the entire amount of iron in some foods is not available to the organism warrants the suggestion that the iron content of a satisfactory diet should exceed by a liberal margin the minimal amount actually found to satisfy the human iron requirement when the element is supplied in a readily available form.

Current Comment

CLIMATE IN RELATION TO PULMONARY TUBERCULOSIS

The role assumed by climate in the treatment of this case has been both interesting and puzzling.¹ The effect of individual variation on the course of a disease allows only one means of study of a factor such as climate, viz, the statistical. The problem with regard to tuberculosis has been recently studied from this angle by Cowles and Chapman.² The data used and the method of attack were carefully considered with regard both to the underlying figures and to statistical reliability. The final study was based on the records of more than 150,000 deaths from pulmonary tuberculosis among the white populations of forty-two states. In the analysis, nineteen elements were considered which, on the basis of a priori reasoning, might be expected to influence the tuberculosis death rate. These included both climatic and nonclimatic factors. By a series of highly technical statistical analyses, six primary variants were included in the final multiple correlation. There was thus conclusive evidence of the independent significance of the factors of (1) percentage of Negroes in the population, (2) percentage of the illiterate, (3) hours of sunshine, and there was strong evidence of the significance of (4) school expense, (5) altitude and (6) occupational index. There was no contention, however, that the probabilities involved afford conclusive evidence as to specific causes, since there is always the possibility that the elements identified as apparently significant may simply be correlated highly with the true etiologic factors. The results indicate that climatic factors are of independent significance, although less so than the nonclimatic. The percentage of Negro population appears to have a considerable direct relationship to the tuberculosis death rate for the white population in the case of thirty-three states with less than 19 per cent of Negroes. In the case of nine Southern states with more than 25 per cent of Negroes, a different relationship is indicated, which might be due to the stricter segregations in these regions. Educational factors, chiefly percentage of white population illiterate and, to a lesser extent, per capita expenditures

in elementary and secondary schools, represent in total importance a large part of the elements disclosed as significant. One climatic factor that seems to be definitely significant is hours of sunshine. Of additional possible significance are precipitation, daily temperature range, and altitude. The general conclusion is that, as far as the United States is concerned, higher standards of education and decreased risk of infection from Negroes, combined with life in a sunny, dry and high altitude climate seem to be more important than other climatic and environmental elements in reducing the white death rate from pulmonary tuberculosis.

Association News

ANNUAL CONGRESS ON MEDICAL EDUCATION, MEDICAL LICENSURE AND HOSPITALS

The Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago, Feb 17 and 18, 1936. The Federation of State Medical Boards of the United States will participate in the congress. The program follows:

MONDAY, FEBRUARY 17, 10 A M

Report of the Council on Medical Education and Hospitals

Ray Lyman Wilbur M.D. LL.D. Chairman Stanford University Calif.

The Accrediting of Higher Institutions

George F. Zook Ph.D., President American Council on Education Washington D.C.

Consistency Versus Chaos in Medical Education and Licensure

Walter L. Biering M.D. Secretary The Federation of State Medical Boards of the United States Des Moines Iowa

The State University and Professional Education

Arthur C. Willard S.B. LL.D. President University of Illinois Urbana

MONDAY, FEBRUARY 17, 2 P M

Swans Sing Before They Die

Elias P. Lyon M.D. LL.D. Dean University of Minnesota Medical School Minneapolis

Scope and Objectives of the Undergraduate Teaching of Obstetrics

George W. Hosmak M.D. New York

Charles B. Reed M.D. Associate Professor of Obstetrics Northwestern University Medical School Chicago

Robert H. Riley M.D. Director State of Maryland Department of Health Baltimore

TUESDAY, FEBRUARY 18 9 A M

The Personality of the Teacher

James S. McLester M.D. President American Medical Association Birmingham Ala.

Some Observations on the Social Background of Medical Practice in Great Britain

Richard E. Scammon Ph.D. LL.D. Distinguished Service Professor of the Graduate Faculty of the University of Minnesota Minneapolis

Instruction of Students and Interns in the Legal Social and Economic Influences Affecting Medical Practice

Stanhope Bayne-Jones M.D. Dean Yale University School of Medicine New Haven Conn.

Can the Present Medical Curriculum Achieve the Proper Aims of Medical Education?

Langley Porter M.D. Dean University of California Medical School San Francisco

TUESDAY, FEBRUARY 18 2 P M

Function of the Hospital in the Training of Interns and Residents

J. A. Curran M.D. Executive Secretary New York Committee on the Study of Hospital Internships and Residencies New York.

The Laboratory of Pathology in the Small Hospital

Howard T. Karsner M.D., Professor of Pathology, Director of the Institute of Pathology Western Reserve University and the University Hospitals Cleveland

Accur Points of View Concerning the Use of the Outpatient Department in Medical Education

W. McKim Marriott M.D. Dean, Washington University School of Medicine St. Louis

THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

MONDAY, FEBRUARY 17, 2 P M

The Federation and the Survey of Medical Schools

William D. Cutter M.D. Secretary Council on Medical Education and Hospitals American Medical Association Chicago

The Two-Year Medical School

George M. Williamson M.D. Secretary North Dakota State Board of Medical Examiners Grand Forks

Benjamin J. Lawrence M.D. Secretary North Carolina Board of Medical Examiners, Raleigh

Comments on National Board Examinations

J. Stewart Rodman M.D. Medical Secretary, National Board of Medical Examiners Philadelphia

Everett S. Elwood Executive Secretary National Board of Medical Examiners Philadelphia

Final Objective

Harold Rypins M.D. Secretary Board of Medical Examiners of the State of New York, Albany

MONDAY, FEBRUARY 17, 6 30 P M

FEDERATION DINNER

Address The Responsibility of a University in Medical Training

Eugene A. Gilmore LL.B. LL.D. President State University of Iowa Iowa City

Address The Art of Medicine

Irvin D. Metzger M.D. President The Federation of State Medical Boards of the United States Pittsburgh

Round Table Discussion—State Board Problems

TUESDAY, FEBRUARY 18, 1 30 P M

Enforcement Procedure

Thomas J. Crowe, M.D. Secretary Texas Board of Medical Examiners Dallas.

Herbert M. Platter, M.D. Secretary, Ohio State Medical Board Columbus.

Aggressive Versus Passive Attitudes of State Board Members

Arthur C. Morgan M.D. Member Pennsylvania State Board of Medical Education and Licensure Philadelphia

Foreign Medical Credentials

Charles B. Pinkham M.D. Secretary California Board of Medical Examiners, San Francisco

Experience with Basic Science Law in Nebraska

Henry J. Lehnhoff M.D. Secretary Nebraska Board of Examiners in Medicine Lincoln.

Narcotic Legislation

William C. Woodward M.D. LL.D. Director Bureau of Legal Medicine American Medical Association Chicago

Executive Session

RADIO BROADCASTS

The American Medical Association broadcasts over the Blue network and certain additional stations of the National Broadcasting Company at 5 p.m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers a toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The next three programs are as follows:

December 10 Hunting Accidents Morris Fishbein M.D.

December 17 Animal Diseases in Man W. W. Bauer M.D.

December 24 No broadcast

This program is broadcast also on the short waves through KDKA, Pittsburgh, over station W8XX, 11,870 and 12,210 kilocycles.

THE KANSAS CITY SESSION

Special Exhibit on Fractures in the Scientific Exhibit

The Committee on Scientific Exhibit of the Board of Trustees has announced that the special exhibit on fractures will be resumed at the Kansas City session under the direction of a committee composed of Kellogg Speed chairman Chicago, Frank D. Dickson Kansas City, and Walter Estell Lee, Philadelphia. For five years from 1927 to 1931 the fracture exhibit was carried on as a regular feature of the annual session but for the last four years it has been omitted.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Chamber of Commerce Honors Physician—A resolution was adopted by the Mobile Chamber of Commerce, October 3, in appreciation of the services of the late Dr. Herbert P. Cole, Mobile, and expressing regret over his recent death. Dr. Cole was a former president of the chamber of commerce.

Hookworm Survey—A survey of all the school children in Baldwin County was begun, October 1, under the direction of Dr. Stephen A. Durick, Bay Minette, county health officer, to determine the presence of hookworm. Specimens will be analyzed in the laboratory of the state health department and reports of the examinations will be submitted to the parents. Children showing a positive report will be given treatment for hookworm free of charge. Examinations of parents and pre-school children will also be made on request.

CALIFORNIA

Popular Medical Lectures—The fifty-fourth course of popular medical lectures for 1936 at Stanford University School of Medicine will be held on alternate Friday evenings, beginning January 3, with Dr. Edward C. Sewall as the first speaker, on "Sinusitis, Allergy and the Common Cold." Other lecturers in the series are:

Dr. Thomas Henshaw Kelly, January 17, Public Patient Physician and Health Insurance.
Dr. C. Frederick Fluhmann, January 31, Superstitions, Facts and Theories of Menstruation.
Dr. George H. Becker, February 14, Success of Control of Communicable Diseases in San Francisco.
Dr. Albert D. Davis, February 28, Value and Limitations of Plastic Operative Procedures.
Dr. Thomas G. Inman, March 13, Present Conceptions of the Nature of Mind.

CONNECTICUT

Changes in Health Officers—Dr. Thomas F. O'Brien has been appointed acting health officer for the city and town of Hartford, succeeding Dr. Charles P. Botsford, who retired after twenty-seven years' service. Dr. John A. Bucciarelli has succeeded Dr. Myron J. Brooks, retired, as health officer of New Canaan. Dr. Michael D. Riordan has been appointed health officer of the town of Windham for a term of four years.

Dr. Nicholas Named Professor of Comparative Anatomy—John S. Nicholas, Ph.D., associate professor of comparative anatomy, Yale University, New Haven, has been appointed Bronson professor of comparative anatomy. The appointment is the first to this chair since 1927, when Dr. Ross G. Harrison, the incumbent at that time, was named Sterling professor of biology in the medical school. Dr. Nicholas received the degree of doctor of philosophy from Yale in 1921. He was associated with his alma mater as assistant in biology from 1917 to 1919 and was instructor in anatomy at the University of Pittsburgh School of Medicine from 1921 to 1922, when he became assistant professor. In 1926 he returned to Yale, becoming associate professor of comparative anatomy in 1932.

DISTRICT OF COLUMBIA

Dr. Coulter Named Tuberculosis Coordinator—Dr. Archibald Barklie Coulter has been appointed tuberculosis coordinator of the District of Columbia. His first task will be to coordinate efforts being made by public and private agencies to locate persons unaware that they have tuberculosis and see that provision is made for their treatment. A campaign against tuberculosis was begun in the district, November 25, with funds made available by the Works Progress Administration.

Radio Advisory Board—An advisory board has been appointed for the radio broadcasts of the Medical Society of the District of Columbia with Drs. Roy Lyman Sexton, chairman, Harry Arnold McNitt, vice chairman, and Herbert P. Ramsey, member ex officio. Representatives on the board for the society at large are Drs. James A. Cahill Jr., Roger S. Cohen, Tomas Cajigas and Robert A. Bier, for the health department; Dr. Daniel L. Seckinger, deputy health officer, for the U. S. Public Health Service; Dr. Ralph C. Williams, assistant surgeon general and for the National Broadcasting Company, Mr. Stanley Bell, technical adviser.

FLORIDA

Personal—Dr. Ralph E. Stevens, assistant surgeon, Veterans' Administration Facility, Bay Pines, has been appointed city physician and superintendent of the municipal public health service.—Dr. Leon H. O'Quinn has been elected mayor of Hialeah.—Dr. Huston J. Banton, captain, U. S. Army Medical Corps, has been appointed a deputy district health officer of the state board of health of Florida.—Dr. Harry C. Galey Jr. was recently elected mayor of Key West.

Public Health Meeting—The Florida Public Health Association held its seventh annual meeting in Orlando, December 2-4, at the Colonial Orange Court Hotel. Speakers included:

Dr. Herbert L. Bryans, president, Florida Medical Association, Attitude of the Florida Medical Association Toward Public Health.
Dr. Halbert L. Dunn, chief statistician for vital statistics, U. S. Bureau of the Census, Washington, D. C., Importance of Vital Statistics to the Citizen.
Dr. Reginald M. Atwater, executive secretary, American Public Health Association, New York, Team Work in Public Health.
Dr. William W. Bauer, director, bureau of health and public instruction, American Medical Association, Coordination of Private Practice and Preventive Medicine.
Dr. Kendall Emerson, managing director, National Tuberculosis Association, New York, Tuberculosis in a State Health Department Program.

A public meeting was held Monday evening, December 2, with the following speakers: Dr. Edward S. Godfrey Jr., assistant commissioner of health of the state of New York, What the Public Should Know About the Control of Diphtheria; Conrad Van Hynning, commissioner of social welfare, Jacksonville, "Public Health Aspects in Social Work," and Dr. James P. Leake of the U. S. Public Health Service, Present Knowledge of Prevention and Control of Poliomyelitis.

GEORGIA

Officers of State Medical Board—Dr. Frank M. Rudley Jr., LaGrange, has been appointed for a term of four years to the state board of medical examiners to succeed Dr. Burr T. Wise, Americus. Drs. James M. Baird, Columbus, and Jesse L. Howell, Atlanta, were reappointed for four year terms. Dr. Baird is president of the board and Dr. Howell, vice president.

Society News—Dr. Alton V. Hallum read a paper before the Fulton County Medical Society, Atlanta, November 7, entitled "Eye Changes in Hypertensive Toxemia of Pregnancy (A Study of 300 Cases)," and Dr. James N. Brawner Jr. gave a clinical talk on "Hormone Treatment of Gonococcal Vaginitis in Children."—At a meeting of the Spalding County Medical Society in Griffin recently, speakers included Drs. Earl H. Floyd and James L. Pittman, Atlanta, on "Operation on the Single Kidney for the Removal of Calculi."

ILLINOIS

State Health Conference—The annual state health conference will be held in Springfield, December 10-11. The control of communicable diseases will be the theme of the two day session and the functions of diagnostic laboratories, essentials of sanitary supervision over milk supplies, practices in public health administration and methods of health education will also be considered. Speakers will include Drs. Logan Clendening, clinical professor of medicine, University of Kansas School of Medicine, Lloyd D. Felton, Baltimore, John P. Koehler, commissioner of health of Milwaukee, and Maud E. Watson, Ph.D., director, child guidance division, Children's Fund of Michigan, Detroit.

Chicago

Drive to Reduce Noise—A campaign against inadequately muffled exhausts of automobile, motorcycle and truck engines will be in force by the traffic division of the city police department during December, it is announced. A summons will be issued to all violators to enforce the city ordinance and state statute that require all motor vehicles to be equipped with adequate mufflers.

Premedical Requirements Raised to Three Year Minimum—Students entering Loyola University School of Medicine in October 1939 must present a minimum of three years of college (premedical) work, according to an announcement from the dean. Accordingly, all students enrolling in the premedical curriculum beginning in the fall of 1936 will be subject to the three year premedical requirement. The premedical requirement was raised from one to two years, to become effective in the fall of 1937.

Dr. Sevringhaus to Lecture at Psychoanalytic Institute—Dr. Elmer L. Sevringhaus, associate professor of medicine, University of Wisconsin Medical School, Madison, will lecture on "Clinical Pathology of Endocrine Disturbances" at

the Institute for Psychoanalysis, December 10 According to previous announcement Dr Solomon Strouse was to have been the speaker but illness has compelled him to leave Chicago for the winter Dr Sevringhaus will also lecture, January 10, when he will review the results of the clinical research of his group during the last few years on the mental and peripheral nervous disturbances associated with various irregularities in the menstrual cycle and during the menopause Those who wish to attend these lectures are asked to notify the institute in advance A luncheon will be held at the Tavern Club, December 10, in honor of Dr Sevringhaus

INDIANA

Outbreak of Food Poisoning in Prison—Seventy-two prisoners in the county jail in Indianapolis became ill immediately after the noon meal November 20, and five of them were taken to the city hospital suffering from food poisoning newspapers reported.

Society News—Dr Emil G Vrtak, Chicago, discussed arthritis before the Montgomery County Medical Society in Crawfordsville, November 21—At a meeting of the Fort Wayne County Medical Society in Fort Wayne, November 19, Dr Carroll S Wright, Philadelphia, spoke on the treatment of syphilis—The Kosciusko County Medical Society was addressed in Warsaw, November 19, by Dr Fred O Clark Syracuse, on sciatic pain A resolution was adopted at this meeting in memory of Dr C. Norman Howard, who died November 11—At a meeting of the Thirteenth District Medical Society, November 6, in Rochester speakers included Drs Aaron Arkin and George H Gardner, Chicago on "Differential Diagnosis of Organic Heart Lesions" and the unhealthy cervix, respectively, and Dr Orus R Yoder, Ypsilanti, The Psychological Management of the Patient—Dr Arthur E. Hertzler Kansas City, Mo., gave the banquet address on "Office Management of Stomach Complaints" Dr Arkin also conducted a heart clinic—The meeting of the Indianapolis Medical Society, November 19 was devoted to a discussion of diseases of the gastro-intestinal tract, the speakers were Drs Homer H Wheeler, Julius H P Gauss and Walker Stoeffler

LOUISIANA

Society News—A symposium on cancer was presented before the New Orleans Parish Medical Society, November 25 by Drs James T Nix, Curtis H Tyrone and Gilbert C Anderson—Dr Emil Novak, Baltimore, delivered a paper before the New Orleans Gynecological and Obstetrical Society, November 29, entitled "Ovarian Tumors"

A Record in Cancer Education—Louisiana has made a striking record in cancer education, according to the *Bulletin* of the American Society for the Control of Cancer Under the chairmanship of Dr John A. Lanford, New Orleans, of the committee on cancer of the state medical society, ninety-two radio talks have been given, 501 newspaper articles have been distributed and thirty-three public meetings with a total attendance of more than 7,400 have been held Seventeen study courses for nurses have also been held

MASSACHUSETTS

Dr Freeman Wins the Warren Prize—The Warren Triennial Prize of \$500 has been awarded by the general executive committee of the Massachusetts General Hospital, Boston to Dr Norman E. Freeman, a member of the staff, for an essay on The Physiology of Gangrene The prize was founded by the late J. Mason Warren in memory of his father and is awarded every three years Previous to 1934 there have been sixteen awards of this prize, thirteen going to men in this country and three to foreigners

Sanatorium Honors Memory of Founder—Sharon Sanatorium Sharon a tuberculosis hospital, has recently published a special edition of its 1929 annual report as a memorial to Dr Vincent Y Bowditch, founder of the institution who died in that year The report entitled "His Last Year" is the thirty-ninth issued by the sanatorium Dr Bowditch was a past president of the National Association for the Study and Prevention of Tuberculosis now the National Tuberculosis Association and at one time was medical director of the institution he founded Sharon Sanatorium was opened in 1891 and now has a capacity of fifty-one beds

Personal—Dr Charles Moline, Sunderland, was recently chosen president of the Franklin County Public Health Association—Dr Alice Hamilton, Boston, recently appointed technical adviser on industrial poisons U S Department of Labor was guest of honor at a luncheon meeting November 21 given by the Consumers League of Massachusetts—The recent retirement of Dr George Burgess Magrath Boston,

as medical examiner of Suffolk County on account of ill health will not interfere with his position as professor of legal medicine in the Harvard Medical School or with his functioning as a consulting medicolegal pathologist.—Dr Riley H. Guthrie, assistant to the commissioner in the department of mental diseases, has been named chief executive officer of the Boston Psychopathic Hospital

MICHIGAN

Dr Lavan Named Health Officer of Grand Rapids—Dr John L. Lavan, for four years director of the department of public health and welfare of Kalamazoo, has resigned to become commissioner of public health of Grand Rapids, effective December 1 Grand Rapids, which is Dr Lavan's home city, has a population of more than 168,000 The new commissioner is a graduate of the University of Michigan Medical School, Ann Arbor He was formerly epidemiologist with the Kansas City, Mo., health department and at one time was health commissioner of Toledo

Society News—At a meeting of the Eaton County Medical Society in Charlotte, recently, Dr Don V Hargrave, Eaton Rapids, discussed gastric hemorrhage.—Dr Frederick A. Collier, Ann Arbor, discussed gallbladder disease before the Oakland County Medical Society, October 20, in Pontiac—Dr Garner M. Byington, Battle Creek, medical director of the Kellogg Foundation was elected president of the Michigan Public Health Association at its annual meeting, November 7, in conjunction with the annual Michigan Health Conference—A symposium on anesthesia was presented before the Wayne County Medical Society, November 4 in Detroit, by Drs James E. Watson, Myra E. Babcock and Francis J. Murphy, all of Detroit

Dinner to Dr Warnshuis—Dr Frederick C. Warnshuis, formerly secretary of the Michigan State Medical Society and now holding a similar position with the California Medical Association, San Francisco was guest of honor at a dinner at the Wayne County Medical Society in Detroit, November 11 Among those present were seven former presidents of the state medical society Drs Andrew P. Biddle, 1917, 1918, Angus McLean, 1920, Guy L. Connor, 1923, Herbert E. Randall, Flint, 1927, Louis J. Hirschman, 1928, Carl F. Moll, Flint, 1932 and James Milton Robb, 1933 In addition, the present president Dr Grover C. Penberthy, attended Dr Warnshuis discussed "Medical Practice in California" before the medical section of the society, November 11, and Dr Hugh L. Stalker, Grosse Pointe, showed moving pictures of the mechanism of the heart beat and electrocardiography

MISSOURI

Pilgrimage to Beaumont's Grave—Members of the St. Louis Medical Society arranged a pilgrimage to the grave of William Beaumont in Bellefontaine Cemetery, November 21, the one hundred and fiftieth anniversary of Beaumont's birth Dr Beaumont was born in Lebanon, Conn., Nov. 21, 1785, and died in St. Louis, April 25, 1853 Wreaths were placed on Dr Beaumont's grave by representatives of the Southern Medical Association, Southern Association of Anesthetists, Missouri State Medical Association, International Anesthesia Research Society and the Midwest Association of Anesthetists and the St. Louis Medical Society

NEW YORK

New Medical School for Syracuse—Federal funds have recently been made available for the erection of a new building for the University of Syracuse School of Medicine, construction to begin December 15 The new building will be a new unit in a medical center that now contains the City Hospital, Syracuse Memorial Hospital and the Syracuse Psychopathic Hospital It will be three stories high and will cost \$1,250,000, according to the *Syracuse Herald* It is expected that the building will be completed within a year

Society News—Drs Leon E. Sutton and Frederick S. Wetherell, Syracuse, addressed the Oswego County Medical Society, Oswego October 15 on "Local Anesthesia in Minor Surgery" and "Present-Day Problems in Medical Economics," respectively—Dr Raeburn J. Wharton, Johnson City recently addressed the Schoharie County Medical Society, Cobleskill, on "Anorexia in Childhood"—Dr Emanuel D. Friedman, Cortland Cortland December 6, on "Encephalitis and Cerebral Vascular Accidents" Dr Peter G. Denker, New York, spoke, November 15, on "Diseases of the Spinal Cord and Peripheral Nerves"—Dr Hugh H. Young, Baltimore, addressed the Glens Falls Academy of Medicine, October 25, on cancer of

the prostate.—Drs Wardner D Ayer, Syracuse, and Joseph S Lawrence, Albany, addressed the Franklin County Medical Society, Malone, October 23, on intracranial hemorrhages and the work of county medical societies, respectively.—Dr Eldridge H Campbell Jr, Albany, gave a lecture on "Early Diagnosis of Brain Tumors" before the Fulton County Medical Society, Johnstown, in October

New York City

Eight Made Ill by Cream Puffs—Eight persons from the lower east side suffered from food poisoning within a few hours after having eaten cream puffs, November 11. All were taken to Bellevue Hospital.

Third Harvey Lecture—Dr Francis Peyton Rous of the Rockefeller Institute for Medical Research delivered the third Harvey Lecture of the winter, December 5, at the New York Academy of Medicine. His subject was "The Virus Tumors and the Tumor Problem."

The Welch Lectures—Dr George Hoyt Whipple, dean and professor of pathology, University of Rochester School of Medicine, Rochester, will deliver the William Henry Welch Lectures at Mount Sinai Hospital, December 12-13. Dr Whipple's subjects will be "Ways and Means of Hemoglobin Construction Within the Body" and "Plasma Protein Regeneration as Influenced by Various Factors."

Resolution Concerning New Hospitals—The Hospital Council of the City of New York at a meeting November 6 adopted a resolution taking the position that it is inadvisable for public or private hospital authorities to commit themselves to any major program of hospital construction without conferring with the council. In the opinion of the council no such project should be launched unless it can be shown to be necessary, timely, reasonably assured of support, and wisely located.

Personal—Dr Nathan Ratnoff, medical director of the Beth Israel and Jewish Maternity hospitals, was guest of honor at a dinner at the Waldorf Astoria, November 12, in celebration of his sixtieth birthday.—Dr Charles Walter Clarke, medical director of the American Social Hygiene Association, has been appointed temporary director of the bureau of venereal disease in the city department of health, a half time position.—Mr Henry C Wright, hospital consultant and for many years president of the Queensboro Tuberculosis and Health Association, died October 24.

Society News—Dr Michael Canick delivered an afternoon lecture before the Medical Society of the County of Queens, November 15, on "Common Rectal Diseases—Office Treatment." Dr Benjamin M Bernstein gave a lecture in October on ulcerative colitis.—Dr Charles F Geschickter, Baltimore, addressed the International Association of Industrial Surgeons, October 31, on "Bone Tumors in Their Relation to Trauma."—Dr Hermann Holthusen, professor of radiology, University of Hamburg, Germany, gave the Middleton Goldsmith Lecture of the New York Pathological Society, December 10, at the New York Academy of Medicine. His subject was "Biological Effects of Radiation on the Cells."—Dr William P Healy gave the fourth afternoon lecture of the New York Academy of Medicine, December 6, on "Significance of Uterine Bleeding in Later Life." Dr George Draper will give the fifth, December 13, on "Significance of the Human Constitution in Clinical Medicine."—Drs Harold J Stewart and Archibald G MacLeod were speakers at a scientific meeting of the New York Heart Association, the heart committee of the New York Tuberculosis and Health Association, December 3, on "Cardiac Output" and "The T Deflection of the Electrocardiogram," respectively.—Dr George F Chandler, Kingston, addressed the Society of Medical Jurisprudence, November 11, on "Causes and Treatment of Crime."—Dr Josephine B Neal addressed the Women's Medical Association of New York City, November 13, on "Newer Developments in Poliomyelitis."

PENNSYLVANIA

Society News—Dr John T Farrell Jr, Philadelphia, addressed the Northampton County Medical Society, Easton, November 14, on "Causes of Bronchial Occlusion and Their Importance in the Production of Respiratory Symptoms."—The Chester County Medical Society sponsored a public health meeting in Chester as its observance of state health day, November 19, speakers were Drs Martha Edith MacBride-Dexter, state secretary of health, on tuberculosis, and Arthur C Morgan, Philadelphia, on progress of medicine in the past fifty years.—Dr Jesse O Arnold, Philadelphia, addressed Washington County physicians at Hillsview Farms Sanatorium, Washington, November 13 on "More Rational Methods in Prevention and Control of Eclampsia," with discussion by Drs Paul Titus, Pittsburgh, and James R Bloss, Huntington, W Va.

Philadelphia

Seminars on Tuberculosis—The second series of graduate seminars sponsored by the Philadelphia County Medical Society, dealing with clinical application of laboratory methods in tuberculosis, began November 29, with the following lecturers: Drs William P Belk, on "Variations in the Blood Count and Their Significance", Jacob W Cutler, "The Sedimentation Rate", Abraham Cantarow, "Blood Sugar and Blood Cholesterol Significance of Variation", Frederick William Sunderman, "Minerals in the Blood and Their Significance." Speakers, December 6, were Henry L Bockus, "Interpretation of Gastric Analysis", Louis H Clerf, "The Gastroscope," and B B Vincent Lyon, "Biliary Drainage." Coming lectures are

December 13 Drs Charles C Wolferth Laboratory Examination of the Heart—Electrocardiographic Interpretation, Isaac Starr Jr, Circulation Time and Minute Volume Studies, Alexander Margolies, Heart Sounds—The Stethograph, Charles L Brown Blood Pressure and Its Variation.

December 20 Drs Joseph B VanderVeer, The Basal Metabolic Rate—A Discussion of Its Determination, Edward L Bortz, Variations in the Metabolic Rate and Their Practical Significance and Francis F Borzell, X Ray and Its Clinical Application.

Research Laboratories Transferred.—The Cancer Research Laboratories of the Graduate School of Medicine of the University of Pennsylvania have been transferred to the Franklin Institute and will be continued under the name of Biochemical Research Foundation. Dr Ellice McDonald will continue as director, with forty-two research workers on the staff. Thomas S Gates, president of the university, explained in his annual report that the change was made because Mr Irene du Pont, who provided funds for the research, could not agree with the university's policy on the question of rewards for scientific research. Last year the university formally adopted the policy that all discoveries should be made available to the public without any profits accruing to the individuals or the institution responsible. Mr du Pont is said to have expressed the opinion that greater progress would be made if some definite form of financial reward was held forth. He also felt it would be well for the foundation to patent discoveries with the intent of using profits or income to pay for further research. Mr du Pont established the cancer research department anonymously in 1927.

Pittsburgh

Research Chemist Honored—Edward R. Weidlem, director of Mellon Institute for Industrial Research, received the Chemical Industry Medal for 1935 at a joint meeting of the New York section of the American Chemical Society and the American section of the Society of Chemical Industry in New York, November 8, at the Chemists Club. Dr Weidlem is a graduate of the University of Kansas, from which he received the master of arts degree in 1910. He received the honorary degree of doctor of science from Tufts College in 1924 and doctor of laws from the University of Pittsburgh in 1930. He joined the staff of Mellon Institute in 1912 and became director in 1921. His investigations in the field of medicine include epinephrine and recently, in cooperation with Western Pennsylvania Hospital, treatment of pneumonia and allied pulmonary diseases.

TENNESSEE

Physicians in Attendance at Births—Eighty six per cent of births reported to the state health department in 1934 were attended by physicians, according to a recent report. In cities the percentage was 98, while it was 82 in rural districts. There were ten counties in which less than half the births were attended by physicians. In 1934 physicians signed 93.3 per cent of the death certificates. Including certificates signed by health officers and coroners, the percentage of certificates correctly signed was 95.6, compared with 93.3 the previous year.

Society News—The Chattanooga Surgeons Club was recently organized with Dr William J Sheridan as president.—Drs John H Musser, New Orleans, and James B McElroy, Memphis, were guest speakers at a meeting of the third color district medical society in Chattanooga in October, on disease of the gallbladder and heart disease, respectively.—Drs Russell A Hennessey and Conley H Sanford, Memphis, addressed the Gibson County Medical Society, Trenton, October 28 on "Treatment of Gonorrhea in the Male" and "Further Experience with Mechanical Drainage of the Lung in Pneumonia," respectively.—Dr John Roberts, Kingston, addressed the Roane County Medical Society, Harriman, October 15, on induced pneumothorax.—Dr James Leslie Bryan and J H Phillips, D D S, Nashville, addressed the Robertson County Medical Society, Springfield, October 15, on "Acute Suppurative Mastoiditis" and "The Middle Ground Between Medicine and Dentistry," respectively.—Dr Robert L Sanders, Memphis was guest speaker at the annual meeting of the East

Tennessee Medical Association in Elizabethton in October Dr Estill L. Caudill, Elizabethton, was elected president.—Drs Charles A. Bender and Frank D. Linn, Memphis, addressed the Memphis and Shelby County Medical Society, Memphis, October 15, on "Ileus" and "Fractures Through the Ethmoid Sinuses," respectively.—Drs Stanton S. Marchbanks and Buchanan S. Wert addressed the Chattanooga and Hamilton County Medical Society, Chattanooga, October 24, on hyperparathyroidism and peptic ulcer.

TEXAS

Changes at University of Texas—At the beginning of the fall term at the University of Texas School of Medicine, Galveston, Dr Jarrett E. Williams, formerly of Durham, N. C., succeeded Dr Jesse Morris Horn as adjunct professor of pathology, Dr William B. Sealy, instructor in anatomy, succeeded Dr Francis J. L. Blasingame as adjunct professor of anatomy. Dr Horn moved to Fort Worth and Dr Blasingame to Detroit. In the department of biologic chemistry, Felix Paquin, Galveston, succeeded Marion Fay, Ph.D., associate professor, Dr Fay resigned to become professor of physiologic chemistry at the Woman's Medical College of Pennsylvania. Dr William S. Carter, who returned to the school as dean to succeed the late Dr George E. Bethel, was guest of honor at a banquet arranged by alumni and former students. Dr Carter was dean seventeen years ago.

New Home for State Medical Association—The Texas State Medical Association has bought a two-story brick residence in Fort Worth as a home for the association and

New home of Texas society

its library. It is near the Medical Arts Building and five hospitals, as well as the business district, the railway stations and the postoffice. The house is said to be in such good condition and so arranged that no alterations will be necessary for immediate occupancy. It has a spacious lawn with trees, flowers and shrubs and has also a garage building which will provide a large storage space. For some time the association has recognized the necessity for larger quarters, especially for the development of its library. It is hoped that with permanent quarters the library will receive endowments not only from members of the profession but from laymen as well. The new address is 1404 El Paso Street, Fort Worth.

WASHINGTON

Personal—Dr Arthur E. Wade, Seattle, has been appointed school physician of the city to succeed Dr Ira C. Brown who occupied the position for twenty-two years.—Dr Roger Anderson, Seattle, was chosen president-elect of the Western Orthopedic Association at the annual meeting in San Francisco in October.

Society News—Drs Delmar F. Bice, Yakima and Frank J. Clancy, Seattle, addressed the Walla Walla Valley Medical Society, Walla Walla, November 14 and the Pierce County Medical Society, Tacoma, November 12, on social medicine.—The Washington State Radiological Society was organized in October with Dr Harold E. Nichols, Seattle, as president and Dr Terence T. Dawson, Seattle, as secretary.—Drs Roger Anderson and Robert D. Forbes, Seattle, addressed the King County Medical Society, December 2, on "Ambulatory Method of Treating Fractures of the Shaft of the Femur" and "Appendicitis," respectively.

WISCONSIN

Memorial Lecture—The University of Wisconsin Medical Society and the Phi Chi medical fraternity sponsored a memorial lecture, November 26 for the late Dr Charles R. Bardeen, dean of the medical school for many years. Dr Anton J. Carlson, professor of physiology, University of Chicago, gave the address on "Science, Medicine and the Common Life."

Society News—Dr Edward F. Barta, Milwaukee, gave an illustrated talk on "Malignancies of the Skin" before the Brown-Kewaunee-Door Counties Medical Society at Alaska, October 25.—Drs Charles K. Maytum and Edwin J. Kepler, Rochester, Minn., addressed the Chippewa County Medical Society, October 23, Chippewa Falls, on "Allergy" and "Syndromes Associated with Diseases of the Pituitary Body and the Suprarenal Glands," respectively.—Drs Frank A. Boeckman, Marshfield and Waldo W. Stiles, Arpin, among others, addressed the Wood County Medical Society, Wisconsin Rapids, October 15 on "Prevention of Scarlet Fever" and "Multiple Myeloma," respectively.

GENERAL

Alpha Omega Alpha Lecture—Dr Anton J. Carlson, professor of physiology, University of Chicago, will deliver the annual Alpha Omega Alpha lecture at the Kansas City session of the American Medical Association, May 14.

Grants Available—The committee on grants-in-aid of the National Research Council announces that it will meet next in March 1936. Applications for grants to be considered at this meeting must be on file with the secretary, Clarence J. West, before February 15. The address is 2101 Constitution Avenue, Washington, D. C. Additional information and application blanks will be furnished on request.

Society News—The Eastern Interstate Medical Economics Conference held a meeting in New York, October 13. Thirty-six representatives attended from seven state medical societies: Indiana, Maryland, Michigan, New Jersey, Pennsylvania and the District of Columbia. Dr Frederic E. Elliott, Brooklyn, is president of the conference and Dr Francis F. Borzell, Philadelphia, secretary.—Dr Walter H. McNeill Jr., New York, was elected president of the New York Central Surgeons' Association at the annual meeting in Columbus, Ohio, October 28.

Medical Supplies for Ethiopia—Medical supplies and equipment, including a truck and half a ton of bandages and other necessities, were recently presented to the Ethiopian government through John M. Shaw, Ethiopian consul general, in New York. The gift was made possible through the work of American Aid for Ethiopia, a national organization of which William Jay Scheffelin, Ph.D., New York, is chairman. Haile Selassie recently appealed for volunteer American physicians, nurses and hospital supplies. In a letter transmitted through the New York Times the emperor advised volunteers to communicate with Dr Thomas A. Lambie, American physician who is secretary general of the Ethiopian Red Cross at Addis Ababa.

Prevalence of Poliomyelitis—One hundred and fifty-three cases of poliomyelitis were reported throughout the United States for the week ended November 2, as compared with 109 for the similar period of 1934. During this weekly period the largest number of cases (twenty-eight) was reported in Massachusetts, while the next highest number (twenty-three) occurred in New York. Pennsylvania came third, with a total of nineteen. For the corresponding period of 1934, Washington had the highest number (fourteen). California and Texas were second with eleven cases each. There were 9,992 cases of the disease tabulated in the first forty-four weeks of 1935, compared with 6,759 for the corresponding period of 1934.

'Fight Cancer with Knowledge'—The American Society for the Control of Cancer, in its November bulletin, announces a nation-wide campaign to educate the public on the subject of cancer. The bulletin points out that the society has spent most of its time surveying and recording basic facts concerning cancer diagnosis and therapy because it wished to make certain that the profession was prepared to care for the increase in work which a campaign of lay education would bring about. The directors of the society have now unanimously agreed that existing facilities are entirely adequate for more patients than are now availing themselves of the opportunity of early diagnosis and treatment. The society's slogan, 'Fight Cancer with Knowledge,' will be the theme of the campaign.

Examinations in Obstetrics and Gynecology—Written examinations and review of case histories of group B applicants for certification by the American Board of Obstetrics and Gynecology will be held in various cities, March 28. Applications for group B must be filed not later than February 28.

The oral clinical and pathologic examination of all candidates for certification will be held in Kansas City, May 11-12, 1936, immediately prior to the scientific session of the American Medical Association. Applications for group A candidates must be received not later than April 1. The annual informal dinner and general conference of diplomates of the board will be held Wednesday evening, May 13, at the Hotel Kansas Citian. For further information apply to the secretary, Dr. Paul Titus, 1015 Highland Building, Pittsburgh.

Southern Surgical Association—The forty-eighth annual session of the Southern Surgical Association will be held in Hot Springs, Va., December 10-12, with headquarters at the Homestead. Among speakers announced on the program are

Dr. Parke G. Smith Cincinnati Anatomical and Mechanical Factors Involved in Nephroptosis
Dr. Waltman Walters Rochester Minn. Successful Plastic Operations for Hypospadias
Dr. Burr N. Carter Cincinnati Technic of Thoracoplasty for Pulmonary Tuberculosis
Dr. Joseph E. J. King New York Brain Abscess
Dr. Bradley L. Coley New York Surgical Treatment of Giant Cell Tumor

At the annual dinner, Wednesday evening Dr. Harvey B. Stone, Baltimore, will be toastmaster, and speakers will be Drs. James Tate Mason, Seattle, President Elect of the American Medical Association, and Robert L. Payne Norfolk, Va., president of the surgical association.

Government Services

Stoner Violates Food and Drugs Act

A fine of \$2000, the maximum penalty, was imposed on 'Dr.' George DeWitt Stoner, Lakeland, Fla., in federal court at Tampa in November for violating the federal Food and Drugs Act. Stoner was placed on probation for two years. In November 1934, Stoner was sentenced for a similar violation and was placed on probation. The recent investigation disclosed that Stoner's wife was continuing the sale of 'Dr. Pene's Uterine Tablets' and 'Regulator Pills' (Compound Pills-Tansy Pennyroyal) to former customers under labels from which the false claims had been removed. The court considered this to be a violation of his probation. Stoner claims graduation from the Curtis Physio Medical Institute of Marion, Ind., in 1896. The institution was said to be a poor excuse for a medical school and the American Medical Association has had no opportunity of checking up the record, since it has been unable to find that there were any records. Stoner also claims to have attended Wichita Medical College and the Hahnemann Medical College. The former had no graduates. The Hahnemann school was closed by its board of trustees. In 1904 this college absorbed the Chicago Homeopathic Medical College. There is no record that Stoner was licensed in Indiana in 1897, as claimed.

Positions for Interns and Residents at St. Elizabeth's Hospital

The U. S. Civil Service Commission announces competitive examinations for positions as junior medical officer at St. Elizabeth's Hospital, Washington, D. C. It is expected that there will be two vacancies July 1, 1936, and two Oct. 1, 1936 for internships and about five vacancies for psychiatric residents July 1. The internship consists of a two year rotating service of four months of surgery, four months of acute medical service, four months of chronic medical service, six weeks each of obstetrics and pediatrics (affiliation), three months of laboratory work and six months of psychiatry. Candidates will not be required to report for examination at any place but will be graded on their education and experience. Applicants for the internship must be senior students in a grade A medical school and applicants for the residencies must have been graduated from a grade A medical school not prior to Jan. 1, 1934 and must have completed an accredited internship. Applicants must not have reached their fortieth birthday on the date of the close of receipt of applications. They must be in sound physical health. Application forms may be obtained from the secretary of the Board of Civil Service Examiners at any first class post office from the commission at Washington, D. C., or at any district office of the commission in the following cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, C. Z., and San Juan, Puerto Rico. Applications must be filed not later than December 16.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 9, 1935

The Right to Die

The formation of a society to promote legislation to render legal the termination of life in painful and incurable disease, at the request of the patient, has been reported in a previous letter. The story of a kindly, elderly family doctor who said he has broken the law and taken life and would do it again if need be is given in the *Daily Mail* by "a special correspondent." Details are not given of the cases, but they were evidently instances of incurable patients dying from cancer, to whom an overdose of morphine was administered. The physician had the patient write a request for release from suffering, which was signed not only by himself but by his wife and family. The act was certainly illegal.

These revelations have given rise to correspondence in the *Daily Mail*. A London consultant writes that no matter how regrettable many aspects of the disclosures may be, the fact remains that in all countries physicians, actuated by the highest humanitarian motives, do at times take what amounts to a sacred judgment into their power. Such actions are jealously guarded, even within the ranks of the profession. Even the nursing staff would generally not be aware of them. Dr. C. Killick Millard, secretary of the newly formed Voluntary Euthanasia Legalization Society, writes that other physicians have told him stories similar to that related. Lord Listowel, one of the founders of the society, states that, while it is impossible to encourage action contrary to the law, the new society has been formed to get the law altered, so that it will be possible to shorten the agony of incurable disease. The society does not think it right that one physician should have the responsibility of such a decision. There should be at least two to decide whether it is impossible for medicine to alleviate suffering.

Some contrary views are expressed. Dr. Estelle Cole, medical psychologist, writes: "When in general practice, I had several cases in which I thought it would have been only humane to end the patient's sufferings. Of course I did not do so and never have heard of any other physician doing so." The *Daily Mail* publishes a cablegram received from Oklahoma City stating that following its disclosures by a physician who had killed five persons suffering from incurable disease a meeting of specialists of international repute was held and ended in condemning "mercy killings." The meeting held that no physician had the right to take a patient's life, since there is no way of being certain that a case is incurable.

In a further instalment of the correspondence, a physician writes: "The vast majority of doctors would be opposed to taking life in any circumstances, ignoring the fact that in their secret hearts they know that on rare occasions cases arise when decisions have to be taken on this supreme matter. What they will strongly oppose is any effort to legalize such a course of action, and for this reason. There is only a comparatively small fraction of cases which one can say with certainty are incurable. The employment of passive euthanasia by the use of pain-relieving drugs is a very different thing from active euthanasia—the deliberate taking of life. The vicar and rural dean of Tonbridge, vice president of the Guild of Health writes: "I feel that doctors cannot be allowed to take the decision on themselves. It would lead to all sorts of complications in the social order."

So far euthanasia has provoked little discussion in the medical press. In the *British Medical Journal* a London practitioner, Mr. Redmond Roche, says that the profession is all out for

"easy dying," but "easy death" is a different matter. It is a claim never made before, and one that he hopes will never be made legal, for physicians to act as executioners. "The claim of this society is against the moral principles of the sanctity of human life. It cuts right across the principles of every school of ethics and the whole hippocratic tradition. It is no part of a physician's duty to decide what is the value of life for his patient, even a life of suffering and apparently hopeless outlook. What is aimed at by this society would eventuate in giving a helping hand to the would-be suicide and allowing sentimentality to overrule our moral and ethical standards." The Roman Catholic press condemns voluntary euthanasia as contrary to religious teaching. Thus it is evident that the movement will have to run the gauntlet of strong opposition from various quarters.

Tragic Fire in a Surgeon's House

London was shocked by the news of the loss of five lives in a fire at a house in Wimpole Street, the second street in importance of the area in the west end, occupied by the medical consultants. The house belonged to Mr. Philip Franklin, an American who has been practicing laryngology in London for some years. The fire broke out at 6.30 a.m. on Sunday while he was away in the country for the week end. All the inmates—his wife, her niece and three servants—perished. They were trapped in their bedrooms on the upper floors when the fire broke out on the ground floor. It was traced to the fusing of an electric cable. It was extinguished by the fire department in forty minutes.

Ambulance Service for Ethiopia

The British Ambulance Service in Ethiopia has organized an expedition which is about to start from London under the direction of a London surgeon, Mr. A. J. M. Melly, who has had considerable experience in Ethiopia. There are five other medical men, of whom one is a Dane. Besides these the unit will consist of three transport officers, six British noncommissioned officers and twenty-four native dressers, who have been recruited from the medical missions in Kenya and Uganda. The project originated some time ago in the formation of a committee that had a personal knowledge of Ethiopia and was appalled at the prospect the Ethiopian troops would have to face when exposed to the destructive effects of the latest engines of war. The expedition is financed by funds raised in England with the cooperation of the British and Scottish Red Cross societies. The estimated cost of maintaining an expedition in the field for three months is \$175,000. Of this only \$95,000 has been raised as yet. It was decided rather than to wait until all the money was collected to send out as soon as possible a smaller unit. Should the funds be available, the unit now sent out will be duplicated. In order to reduce expenses the members of the unit will travel second class. The Swedish Red Cross Ambulance Service has already sent out two detachments to Ethiopia, including six doctors of whom two are bacteriologists. A Swedish aviator has placed his own airplane at the service of the mission.

Health Study Tour of the United States

Dr. R. M. F. Picken, professor of preventive medicine in the Welsh National School of Medicine, has been appointed by the Health Organization of the League of Nations as representative of Great Britain on an American study tour. Six countries are represented. Each member represents various interests in the field of preventive medicine. The tour was to begin at Washington November 4 and end in New York December 7. The health services generally of the United States will be discussed. The places visited will include Baltimore, Knoxville, Nashville, St. Louis, Chicago, Cincinnati, Columbus, Detroit, Philadelphia, Boston, Cattaraugus County and New Haven.

Street Accidents to Pedestrians

The total number of persons killed in the streets of London in the forty-three weeks ended October 26 was 893 and the number injured was 48,377. In the past week fourteen pedestrians were killed. Of these eight were over the ages of 55 and five over 69. In the forty-three weeks ended October 19, 262 pedestrians over the age of 55 were killed, 143 between 10 and 55 and 114 under 10. It is evident that the proportion of persons of advanced years and of children killed is much greater than for the intermediate period of life.

PARIS

Negative Skin Reactions in the French Army

A large number of individuals develop a primary tuberculosis in adolescence or even later in life, as Troisier, Barety and Nico showed in papers published in 1934 in the *Annales de médecine*. At the July 9 meeting of the Académie de médecine they reported a statistical study of the skin reactions of 132 soldiers in apparent good health, the majority from 20 to 21 years of age. Thirty-three of the 132 (25 per cent) had markedly negative, four had doubtful and fifteen had delayed reactions. Only 60.6 per cent had a positive reaction. Of the 132 soldiers fifty-seven came from villages of 2,000 or less inhabitants. Twenty-three of the fifty-seven, or 40.4 per cent, had negative, eleven, or 19.2 per cent, had doubtful or delayed, and only twenty-three had positive reactions. For the seventy-five soldiers born in cities, the percentages are nearer those considered typical, viz., fifty-seven (76 per cent) had positive, eight doubtful or delayed and ten negative reactions. In the discussion Debre emphasized the necessity of a widespread use of the tuberculin skin reaction. Too many physicians take it for granted that it is always positive in older children and adults. Lereboullet stated that, in the children's hospital of Paris, only after the age of 12 years does the positive reaction reach a percentage of 50, and then it rises to 75 at the age of 13 years. Sergeant has observed from 18 to 20 per cent of negative reactions in medical students working in his tuberculosis service. The majority of these students came from rural districts and should be carefully watched.

Prevention of Tuberculosis in Medical Students with BCG Vaccine

Scheel of Oslo (Norway) reported his observations from 1926 to June 1935 with the Pirquet and Mantoux tuberculin skin tests on 1,225 students who worked in the tuberculosis wards. The report was read at the July 25 meeting of the Academy of Medicine by Professor Guérin of the Pasteur Institute. The students may be grouped as follows: Group 1 includes 361 students having a positive skin test before and two months after entering the ward service. In this group the positive reaction antedates any possible hospital contamination. Group 2 includes 207 students with negative tests prior to entering the wards. Group 3 includes 295 with negative tests before beginning their service and who had been given the BCG vaccine. Group 4 includes 262 students whose tests were positive two months at least after and also during their entire service in the wards. It is impossible to ascertain whether the positive tests existed before their ward work began. Group 5 includes 100 who had evidences of tuberculous infection before entering the wards. All had positive tests with one exception. For the first four groups not having presented evidences of tuberculosis before their ward work, the occurrence of positive tests shows a gradual rise from the age of 16 (34 per cent) to that of 22 years (54 per cent) and a sudden rise between 22 and 25 years to 72 per cent. The ward work was usually begun at 25.

In the case of the nurses in the tuberculosis wards, the percentage of positive skin tests rises from 50 to 100 during the first three years of their service

The average annual morbidity (tuberculous) in the different groups was noted in the case of 1,024 students. Group 1 (262 students), students with positive skin test before entering the wards 135 per cent. Group 2 (144 students), negative test before ward work 46 per cent. Group 3 (295 students), negative test before service but given BCG vaccine 195 per cent. Group 4 (237 students), test found positive during ward service without any knowledge as to result of tests before 238 per cent. Group 5 (eighty-six students), with signs of tuberculosis before beginning service 280 per cent. These figures show that the morbidity is higher among students doing work in tuberculosis wards than among the population of Norway in general, hence students working under these conditions must be protected against contracting tuberculosis. Those having negative skin tests show a morbidity three times as high as that shown by those with positive tests. The benefits of BCG vaccination are evident in group 3 the 295 students had negative skin tests on entering the service and were then given the BCG vaccine with a resultant morbidity of only 195 per cent.

Of the 355 vaccinations given to those in the third group and to others not in the group, 321 were given subcutaneously thirty-four by mouth. The initial dose of the latter was 50 mg

Recent Developments at German Universities

Some time ago reference was made to the marked reduction in the number of students studying at German universities. The reduction was much greater than the authorities had anticipated and led soon to the abolition, or at least the toning down, of restrictions. It seems now, from an examination of statistics of German universities, that the reduction has been considerable. For the summer semester of 1932 the total attendance at the German universities was 129,606 for the winter semester of 1934-1935 it was only 86,865, a decrease of about one third. The number of new entrants for the study of medicine dropped from 4,900 for the school year 1931-1932 to about 1,500 for the school year 1933-1934. (Some subjects, however, showed an increase. Catholic theology, training course for teachers in the public schools, agriculture, forestry and mining engineering.) The shifting in the social strata finds expression in the fact that, of the new entrants for the summer semester 1934 a higher percentage of students belong to the classes represented by minor officials, small land owners, peasants and workmen than has ever previously been the case. On the other hand, the percentage of children of middle-rank officials has declined. By reason of the lowered birth rate during the war, it is thought that the next few years will bring a further reduction in the number of students. Not until 1940 is it anticipated that there will be any considerable increase.

By reason of this great reduction in the number of students, the maximal number of students allocated to the various universities has in some instances been increased. The University of Berlin has been allowed 6,900 students in place of 5,600, a number of other universities located in large cities have had their allocation increased. Requests for admission will be considered in the following order: (a) "veterans" of the national-socialist party, (b) members of the defense forces, provided they are pursuing studies at the command of their military service centers, for later use in the army service, and (c) students who have studied at the two eastern universities Königsberg and Breslau (these two universities, as being frontier centers of German thought, are shown some preference). These provisions do not apply to foreigners.

The general aspect of the student body has changed greatly. Characteristic is the official declaration "Hitler youth and the student body of the universities are the natural supporters of the political struggle of our youth." Especially sharp was the struggle for the preservation of the student "corporations," or corps, which have been for many years a characteristic feature of German universities. A few months ago, this struggle, to which reference has been made in previous letters, was brought to a near close when the League of Corps Students, the so-called Kösener Senioren-Konvent, declared publicly its adherence to national socialism and took the oath of fidelity and loyalty. This occurred in June of this year. On September 25 an order was issued forbidding *fuehrer* and members of the Security League to belong to a chapter of the Kösener SC "because the Kösener SC has publicly refused to carry out the principle of Aryanism." In other words, no one would be allowed to belong to an SC corps or to a league of alumni composed of former members of a given corps, on pain of dismissal from the *Sicherheits-Abteilung*.

Soon after publication of this order, developments were rapid. October 1 the Kösener SC was dissolved of its own free will. No doubt this step was taken in anticipation of compulsory orders to be issued by the central government or the ruling party. The upper strata of German society, the nobility, the bureaucracy, big industry and the bench are permeated with former corps students. It is evident that this opposition, which has continued now over two years, was directed primarily against the "upper classes." The bone of contention, however, was the Jewish problem, for several student corps had steadily refused to eject their non-Aryan members. Pure-blood Jews were seldom involved but rather offspring of mixed marriages. Now that the Kösener SC has been overthrown, the individual student corps at the universities will have rough sledding. In fact, some universities have suspended the student corps. From the standpoint of the present government one can understand that the student corps were a thorn in the flesh. It might be recognized that they brought out many good qualities in their members, yet their esprit gave rise to many things that were not so desirable, for example, their exaggerated exclusiveness, by reason of which an old corps student would often assist a corps brother along the path of life irrespective of whether or not he was deserving of aid. The result of this overemphasis on "connections" has sometimes been that good positions have not gone to the "worthiest and best" but rather to corps brothers. The more serious members of the SC league have often observed and regretted this fact. On the whole, it must be admitted that the class pride displayed by some of the corps students was exaggerated and objectionable. With this league there has disappeared an eighty-year-old tradition, which had accomplished much in the way of character building and had contributed a great deal toward the development of a spirit of camaraderie.

A few days after the dissolution of the Kösener SC, the other large student league, the "Deutsche Burschenschaft," followed suit. In contrast with the student corps, however, whose views formed a sharper contrast with those of the national socialists, the burschenschaften have acquiesced submissively and have thereby turned their backs on their liberal past. Their 110 chapters have been united with the *Nationalsozialistischer Studentenbund*. The bright cap and other insignia of the burschenschaften, which have helped to give a colorful aspect to the German universities, will disappear. Ever since the World War the burschenschaften have shown a tendency to sacrifice their traditions of a hundred years ago, when they were leaders in their support of liberal democratic ideas, and to embrace the newer ideas of the national socialists. It is evident that the leveling process is making rapid headway in the fraternity life of German university students.

The federal minister of public instruction has issued new regulations concerning the admission of students to the "Reichs-schaft der Studierenden an den deutschen Hoch- und Fach-schulen." Without exception, only such students may be admitted to local student bodies as "can prove, in accordance with the regulations of the national-socialist party, that they are of Aryan origin and of true German stock. In case of doubt, documentary evidence back to the year 1800 may be demanded." An official announcement has been published to the effect that "the decree constitutes another forward step in the application of the principle of Aryanism."

Of the 91,480 German students (exclusive of foreigners) attending German universities during the summer semester of 1934 (the last semester for which complete statistics are available) 656, or about 0.71 per cent, were of the Jewish faith. In addition there was a group of non-Aryans who cannot be identified on the basis of statements as to their religious faith but who are known from the fact that they are not admitted to the German student body. The total number of non-Aryans (exclusive of foreigners but including the pure-blood Jews) is 1,316, or 1.44 per cent of the total number of students of German citizenship. Hence it may be concluded that there are twice as many students of Jewish race as there are open adherents of the Jewish faith. In the summer semester of 1934 there were only twenty-four Jews among the first-semester entrants out of a total of 6,189 (excluding foreigners). Of the 4,350 foreign students, 364 were found to be of the Jewish faith, of this number, 208 were studying medicine or dentistry.

New regulations pertaining to examinations given non-Aryan medical students have likewise been announced. If these began their studies before the summer semester of 1933, they will be admitted to examinations in the scheduled manner. But passing of their examinations does not entitle them to a license to practice. If, however, they began their study of medicine or dentistry in the summer semester of 1933, they can be admitted to examinations "only in exceptional cases and that only with the special consent of the minister of the interior. Foreigners will be admitted to the examinations without being obliged to furnish evidence of Aryan origin. The following citation from the regulations is revealing: "The licensure (the right to practice medicine or dentistry) will not be granted to non-Aryan physicians or dentists until further notice. Only in a few exceptional cases, which must be presented to the minister for his decision, will a license to practice be granted. An exception will usually be made if the candidate fought at the front in the World War, or if only one of his four grandparents was Jewish (thus having only a quarter Jewish blood), or if his bearing and appearance are unobjectionable."

ITALY

Sept 30, 1935

Society of Anesthesia and Analgesia

The Società di anestesia e analgesia held recently its first meeting at Turin, jointly with the Società Piemontese di chirurgia, in which many foreign physicians participated. Papers were presented that dealt with the use of carbon dioxide in surgery. According to Bogetti, the administration of carbon dioxide during anesthesia suppresses the initial state of excitement and in addition increases the depth of inspiration and prevents respiratory syncope. It combats also hypotension and inhibits nausea and vomiting.

Peracino reported the results secured in the Ospedale Mauriziano in Turin over a period of three years from the administration of carbon dioxide during and after anesthesia. It has always aided the respiration during anesthesia. The reawakening is more rapid and is without nausea or vomiting.

Coronedi pointed out that, following acute poisoning due to barbituric compounds grave symptoms involving the broncho-

pulmonary apparatus are observed. This is due to the fact that, because of the intoxication, the respiratory movements are extremely limited. The inhalation of carbon dioxide-oxygen mixture is an excellent prophylactic means and an auxiliary remedy in combating intoxications of this nature.

Another series of papers dealt with the treatment of pain. Foa pointed out that ultraviolet irradiation with long waves has an immediate but not an enduring action, whereas ultraviolet irradiation with short waves gives more permanent results. In some cases the application of roentgen rays, he has observed, effects a cure of neuralgic disorders, which is permanent in about 60 per cent of the cases.

Segre spoke on posttraumatic spinal algias, emphasizing the importance of a thorough radiologic examination. In cases that he treated he brought about a permanent cure of peripheral algias by means of subarachnoid alcoholization of the posterior roots, thereby blocking the central nerve paths that transmitted the pain sensation.

Trueta of Barcelona discussed splanchnic anesthesia, which he used in interventions on the stomach, combined with local anesthesia applied to the stomach wall. In 771 cases he obtained excellent results, securing absolute anesthesia in 96 per cent. The number of complications in the form of bronchial pneumonia was reduced two thirds, as compared with the number recorded for ether anesthesia.

Giordanengo reported that in the surgical clinic at Bern, during the previous twenty years, in goiter operations local anesthesia was applied to the subcutaneous tissues and to the superficial cervical plexus by means of very dilute anesthetic solutions. With this method one avoids the blocking of the vagus and the recurrent nerves, together with the consequent complications.

Giorelli discussed the problem of anesthesia as applied to dentin and pointed out that all the preparations that produce insensibility in dentin exert a destructive action on the tooth pulp, as was demonstrated in a number of photomicrographs that he presented, which revealed changes in the tooth pulp due to the application of anesthetic substances to the surrounding dentin.

Roccia spoke on infection as a complication of local anesthesia in stomatology. He holds that in the majority of such cases the local infective process is due to the introduction of bacteria with the needle, during the injection. Local anesthesia has no drawbacks if its use is confined to inflammatory processes without suppuration but it should not be used in the treatment of purulent foci. It exerts a harmful action on the defense mechanism of the tissues.

According to Ruspa, local anesthesia and nerve blocking supply the deficiencies of all the systems of dentin and pulp anesthesia and give excellent results also in devitalization of the teeth.

Pejrone explained the technic of anesthetic injections in dental medicine and emphasized the importance of the degree of pressure applied in injecting the fluid, and the temperature of the fluid injected.

Kirschner of Heidelberg illustrated, in a film, his method of spinal girdle anesthesia induced by means of air. He injects into the dural sac a certain quantity of air, a total of about 22 cc, and an anesthetic solution that has the properties of being lighter than the spinal fluid and of not becoming readily diffused. Several different strata are formed, in the lowest strata is the spinal fluid, in a second strata above is the anesthetic, and above that is a strata of air. By regulating suitably the position of the zone with the anesthetic, the zone of insensibility can be shifted at will. Three thousand cases have demonstrated the value and the advantages of the method.

Figueras of Barcelona uses epidural anesthesia, employing procaine with epinephrine. He secures complete anesthesia in about 85 per cent of the cases, without grave incidents. He

recommends the method especially for interventions on the kidney and on the biliary tracts

Pescarmona secured good results with nupercaine in 500 cases of spinal anesthesia, with rare and transitory untoward incidents. It is necessary, however, to establish the exact indications, to prepare the patient carefully for the anesthetic, and to apply the exact technic of spinal anesthesia.

Ceremonies in Memory of Francesco Folli

Physicians from nineteen countries met recently at Poppi (Arezzo province) to honor the memory of Dr. Francesco Folli, who was the first to employ blood transfusion. Born at Poppi in 1624, this learned physician, in his publications "Recreatio physica" (1665) and "Dialogo sulla cultura delle vite" (1670) explained his idea of transfusing the blood of young and healthy persons to old or sick persons and described the instruments needed for the intervention.

The commemorative address was delivered by Professor Pazzini of the University of Rome.

Professor Cerletti Called to the University of Rome

The faculty of medicine of the University of Rome has asked Prof. Ugo Cerletti, formerly director of the university clinic in Genoa, to accept the chair of nervous and mental diseases at the University of Rome. After finishing his course of training in Rome, Cerletti continued his studies in German and French clinics. His works on the diseases of the cerebral blood vessels and of the meninges, and on the lesions of the cells and of the nerve fibers, are original in thought and classic in mode of expression. His new conception of the structure of the neuroglia, which has been accepted by many leading authorities, changes radically the old conception of Weigert.

BUDAPEST

(From Our Regular Correspondent)

Oct. 18, 1935

The Ninth International Dermatologic Congress

Prof. Louis Nékám of Budapest University, president of the ninth International Dermatologic Congress, opened the congress in the parliament building in Budapest. The Hungarian parliament reaches back to the beginning of the eleventh century. The foundation of the capital city took place, under the name of Aquincum, almost 2,000 years ago. Our scientific academy as at present organized dates back 110 years and our university 300 years. He said that the task of our congress is to further dermatology. Development in dermatology proceeds in the form of waves every fifty to sixty years. In the last 150 years three such waves have passed and the fourth is now under way. The approximate date of the first one was 1780, of the second 1835, and of the third 1880. In the first wave, two thoughts awakened the stagnating dermatologists. One of them carried the names of Plenck of Budapest, Lorry of Paris and Willian of London, who first emphasized the importance of pathologic symptoms and demanded the thorough examination of the patient. The second thought was presented in the method of Hunter, who said that in case of doubt one should appeal to experiments.

The second wave began 100 years ago. In 1834 Renucci demonstrated the mite of scabies, it was then discovered by Bassi and Balsamo that fungi are capable of killing the silk-worm. In 1835 appeared Alibert's great monograph and Rayner's manual on the diseases of the skin. Dermatologic knowledge advanced to such an extent that Cazenave thought of editing a dermatologic magazine. During this time the question was not "what?" but "why?" Dermatologists saw the changes and wanted to know their causes. One after the other entered the arena: the Frenchman Bichat, the Austrian Rokitan-sky, the German Virchow and the Italian Morgagni. Gradually

scientific morphology evolved. Every day new discoveries were made. People saw with amazement what immense importance attaches to the most minute living things. Conditions a hundred years ago must have been very primitive. When Hebra took over his hospital section in 1844, 2,173 of his 2,723 cases were diagnosed scabies. But could it be otherwise? Nothing was yet known about the function of the spleen, bone marrow, lymph glands, internal glands, sympathetic nerves or the reticulo endothelial system. The present laboratory tests had not been discovered. Today every assistant is making analyses with much more exact results than did Laënnec and Shoda.

In the year 1880 came the third wave—bacteriology. Pasteur and Koch founded many new conceptions, such as virulence, vaccination and immunity. Hand in hand with this went in the next fifteen or twenty years recognition of the fact that, besides the etiologic agent, the attacked organism itself is an important determining factor of the pathologic process, and that its reaction or counter attack was also of great influence.

With this a new age was reached in which it appeared that there are still much tiner things than bacteria, than the ultra microscopic beings, these are emanations and rays, which may attack the organism. In this age protection against diseases will be reached not by isolation or quarantine but by training, panimmunity and insusceptibility. Of course this requires a higher realization of the ideals of medical sciences. These perspectives have been a guide in preparing the program of the congress. The most important questions were considered: the correlation of functions, the filtrable viruses, the disturbances of metabolism, heredity, tuberculosis, venereal diseases, lepra, lymphogranulomatosis, industrial diseases and cancer. These were chosen to be dealt with from the scientific point of view and discussed also at separate conferences from the social and hygienic points of view. Besides special committees were organized which should endeavor to make terminology systematic and to frame definitions and basal conceptions. In 1896 Hutchinson said that it would be the greatest blessing if terminology and classification might be improved and that the start had to be made by dermatology. "Names are good servants but bad masters," he said.

Committees were named to deal with the training of dermatologists and with the discussion of the ethical, technical and economical conditions of dermatologic practice. The reports of these committees will appear in a separate volume. Many instructive preparations, historical exhibits, the results of research and technical instruments were shown.

JAPAN

(From Our Regular Correspondent)

Oct. 10, 1935

The Average Size of Japanese Students

About thirty years ago the height of schoolboys at the age of 7 was 107 cm and of schoolgirls 105.8 cm, at present the corresponding measurements are 108.5 and 107 cm. At the age of 13 when they finish the six years course of the primary school the height of the boys was 133.6 cm thirty years ago and of the girls 133.6 cm, the corresponding measurements now are 137.1 and 138.5 cm. This shows that girls grow taller than boys during these years by 1.5 cm on an average. At the age of 21, when they usually enter the university, boys were 160.7 cm in height but now are 163 cm, that is, they become about 55 cm taller than they were at the age of 7. When the girls are about 19 years old they were 147.5 cm in height but at present are 151.2 cm. They are shorter than boys by 12.5 cm but they become 44 cm taller than they were at the age of 7. According to their respective ages, the boys grew 3.9 cm every year on an average, and they have their best yearly growth of 3.6 cm to 8.5 cm at the age of 14 or 15. With the girls the average increase of height is 3.67 cm and the

best growth is seen when they are 13 or 14 years old, the average increase being 53 cm to 58 cm. As for their weight and the circumference of the chest almost the same tendency is observed. The average increase of the weight of boys during their school life is between 36.2 and 37.3 Kg. of the girls between 27.9 and 28.8 Kg. The girth of boys increases by 27.9 to 28.8 cm., of the girls between 24.4 and 25.6 cm. Boys in the first year class in modern primary schools are heavier than the former boys by 0.5 Kg and the girls by 0.4 Kg. As for the girth of the chest, the boys have an increase of 0.5 cm but a decrease is found in the girls.

The Board of Medical Inspectors

The Board of Medical Inspectors met September 19 at the bureau of education, to discuss the problem of how to support private medical educational institutions. The inspectors required that the bureau of education grant these institutions financial assistance. The regular examination made by the inspectors is reported as having brought good results. Another subject discussed was a medical course to be opened for foreign students to this country. There are many Chinese, Filipinos and Siamese who want to finish their medical training in Japan within a comparatively short time. The board agreed that the new course should be satisfactorily adapted to the needs of students who come from foreign countries. There should be two years' preparatory study, chiefly for training in the language, and after that four years of medical training. The six year course is expected to be established by some private medical colleges as the government medical colleges are not authorized to receive foreign students as regular students. At the same time, Manchukuo is in urgent need of more practitioners in the interior of the country. Unfortunately Manchukuo does not have a medical school but must send students to Japan to be educated. Those two needs are to be met by private schools. Another subject discussed was the amalgamation of some medical schools that are in financial difficulties. This is of course desirable, but most of the medical men concerned do not desire amalgamation.

The Health of High School Students

After a year's investigation a report on the health of the pupils of the middle grade schools was issued by the sanitary section of the educational department. These schools are attended by boys and girls from 14 to 18 years of age. In 1934, of a total of 736,500 pupils 2,092 died 3,766 were obliged to leave school on account of sickness 9,734 were compelled to stay away from school a long time through sickness and 47,884 were absent from school for more than a week on account of sickness. The sickness for the most part was tuberculosis. One of the main causes of so much tuberculosis must be competitive examinations. Even the children in the primary schools are forced to prepare themselves in order to enter any good schools. The lack of proper sanitation in the schools must also be a cause and is due to the poverty of the local government. Private bodies of various kinds such as the parents association in the primary schools, are organized to provide needed equipment.

Personals

Prof. Dr. N. Hayashi, famous for his lifelong devotion to research on tsutsugamushi disease, has closed his research laboratory in the prefecture of Nagata where he has rendered such great services in prevention of the disease. The mayor of Nagaoka held a farewell meeting in his honor and decided to give a subsidy of 1,500 yen a year to have his research continued at Nagoya.

Dr. Yutaka Tateki has been appointed chief professor of the Nagasaki medical college, to succeed the late Prof. Dr. Komuro. In the general election of members of the prefectural assemblies, held in the latter part of September throughout the coun-

try, 126 medical men were candidates and sixty-six were elected. This fact shows that medical men are much interested in the politics of the local government and are leaders in their own districts.

Marriages

JOHN E. HARTSAW, Cristobal, C. Z., to Miss Hannah Washington of Guayaquil, Ecuador, at Balboa, October 16.

IRMA CARLENS HENDERSON to Mr. William E. Smathers, both of Asheville, N. C. at Hendersonville, November 3.

JOHN M. BRAND, Spencer, W. Va., to Miss Mary Colebank of Morgantown, in Huntington, November 2.

SAMUEL BUTLER GRIMES, Baltimore, to Miss Elizabeth Brawner of Washington, D. C., October 19.

DONALD C. WILKINSON, Oconomowoc, Wis., to Miss Ruth Halloran of Des Moines, Iowa, October 12.

ADOLPH E. DREVEL, Palatka, Fla., to Miss Charlotte Leah Shapps of Wilkes-Barre, Pa., November 6.

PAUL D. MCCARTY, Ely, Minn., to Mme. Delphine Sames-Schacht of Virginia, in Chicago, recently.

HERMAN HARRISON BRAYTON, Chase City, Va., to Miss Ann Norfolk Grimm of Baltimore, recently.

MARTIN CARL LINDMAN, Rockford, Ill., to Miss Alice Dorothy Port of Youngstown, Ohio, March 31.

SAMUEL LINN GROSSMAN, Harrisburg, Pa., to Miss Mary Quinn of Bayonne, N. J., October 19.

WILLIAM B. BURLISON to Miss Amanda Elizabeth Godfrey, both of Plumtree, N. C., August 29.

FRANK KELLS BOLAND JR. to Miss Octavia Norfleet Riley, both of Atlanta, Ga., November 14.

JAMES J. GWIN, Hartsville, Tenn., to Miss Elsie Evins of Culleoka, at Carthage, October 18.

JACOB JOSEPH SILVERMAN, Staten Island, N. Y., to Miss Myn Reich of Orange, N. J., October 3.

FRANK KARSTENS DEAN, Madison, Wis., to Miss Gladys Paust of Columbus, September 30.

EDGAR MARVIN LANCASTER, Shady Dale, Ga., to Miss Jewel Moats of Fairburn, September 14.

FRANK E. DREW, Milwaukee, to Miss Irene Wollaege, at Pine Lake, Wis., September 7.

WILLIAM D. BURKHALTER to Miss Alice Novella Graves, both of Nashville, Tenn., October 3.

CLIFFORD O. MCCREEDY, Alledo, Ill., to Miss Permella Donaldson of Monmouth, October 24.

BENJAMIN HALPORN, Oberlin, Pa., to Dr. MIRIAM REWALT Polk of Harrisburg, July 11.

HENRY KIRVIN SPEED JR., Sayre, Okla., to Miss Ruth Armstrong of Norman, recently.

ARTHUR J. ROSER, Arcola, Ind., to Miss Lillian Kluger of Indianapolis, September 8.

NORRIS EDWARD LENAHEAN to Miss Ernestine Little, both of Columbus, Ohio, recently.

ARMER H. STOLPESTAD, St. Paul, to Miss Evelyn K. Gordon of Minneapolis, recently.

WILLIAM H. ROE Patchogue, N. Y., to Miss Alice Ongaro of Astoria, September 7.

GLENN R. STAUFF, Green Bay, Wis., to Miss Mildred Witters of Hilbert, October 11.

DAVID E. MARKSON to Miss Esther N. Anderson, both of Chicago, October 12.

MARTIN G. ERICSSON to Miss Martha E. Anderson, both of Chicago, October 26.

THOMAS C. GUTHRIE, Smithville, Ark., to Mrs. Ora Ashburn of Imboden, recently.

CHARLES A. LEBERTHART, Atlanta, to Miss Avis Barr of Bowdon, Ga., August 31.

JAMES H. CARSON, Martins Ferry, Ohio, to Miss Esther Horswell, recently.

GEORGE W. JOHN to Miss Pauline F. Poudrier, both of Beloit, Wis., October 15.

DAVID H. SMELTZER, Youngstown, Ohio, to Miss Florence Buehrle, recently.

PAUL J. LEAHY, Tiffin, Ohio, to Miss Mary Quinn of Erie, Pa., recently.

DEATHS

Deaths

Edward Starr Judd of Rochester, Minn., President of the American Medical Association in 1931-1932, died of pneumonia, after a few days' illness, in the Presbyterian Hospital, Chicago, November 29. Dr Judd was on his way to address a meeting in Philadelphia when he was taken ill. Born in Rochester, Minn., July 11, 1878, he graduated from the University of Minnesota School of Medicine, Minneapolis, in 1902 and then became an intern in St. Mary's Hospital in Rochester. In 1903 Dr Judd became first assistant to Dr Charles H. Mayo, and in 1904 he was appointed head of a section in the division of surgery at the Mayo Clinic, later he was appointed surgeon at St. Mary's Hospital in Rochester and professor of surgery in the graduate school of the University of Minnesota, positions which he has filled with distinction for many years. Dr Judd served during the World War as director of the school of instruction for officers and enlisted men of the medical corps in Rochester. Since the war at times he had given of his talent and experience in the training of medical reserve officers. He contributed much to the advance of surgery, having long been recognized as a foremost leader and teacher, especially in surgery of the abdomen. Attesting his great work and ability are his numerous scientific articles in the periodical medical literature and textbooks, numbering more than 200. One of the latest papers published in THE JOURNAL, November 23. Dr Judd was a favorite lecturer and traveled thousands of miles during his career to address medical groups and societies. He was from the beginning of his career an indefatigable worker in organized medicine in county, state and national medical societies. He served as president of the Minnesota State Medical Association, was secretary of the section on surgery, 1913-1916, and chairman, 1917-1918, and in 1918 was elected second vice president of the American Medical Association. He was also a member of the Council on Scientific Assembly of the American Medical Association from the time it was created in 1915 until the conclusion of the annual meeting in Washington, D. C., in 1927. While President-Elect he was chosen to give the first address of the Mayo Lecture-ship in Surgery at Northwestern University Medical School in Chicago in April 1931, a lectureship that was endowed by Dr Charles H. Mayo for the advancement of learning in surgery. Dr Judd was a member of the Minnesota Academy of Medicine, the Minnesota Pathological Society, the American College of Surgeons, the Surgical Association, the Southern Minnesota Medical Association, the Association of Resident and Ex-Resident Physicians of the Mayo Clinic, Sigma Xi, and an honorary member of several scientific societies of foreign countries. Dr Judd was married to Miss Helen Berkman of Rochester in 1908. Among his five children is a son who is a senior at Rush Medical College. Surgeons everywhere have spoken of the surgical mastery of E. Starr Judd, calling him a surgeon's surgeon and the greatest of the great. Men came from the four corners of the world to witness him at his routine work. He was modest, sincere and earnest—a man with beauty of character and greatness of spirit. His death fell on those who knew him like an overwhelming blow.

George Elgie Brown of Rochester, Minn., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909 associate professor of medicine, Mayo Foundation, University of Minnesota Graduate School of Medicine, in 1921 came to the Mayo Clinic as first assistant in one of the sections in the division of medicine and was appointed associate in 1922,

served with the Rockefeller Foundation in France in 1918 and 1919, member of the Central Society of Clinical Research and the American Society for Clinical Investigation, fellow and formerly regent of the American College of Physicians, consulting physician and head of a section on medicine of the Mayo Clinic, author of numerous articles, aged 50, died, November 28, of pneumonia.

Henry Joseph Fitzsimmons, Boston, Harvard University Medical School, Boston, 1908, member of the Massachusetts Medical Society, fellow of the American College of Surgeons, instructor in orthopedic surgery at his alma mater, assistant surgeon to the Children's Hospital, orthopedic surgeon to the Newton (Mass.) Hospital, orthopedic surgeon to the St. Mary's Infant Asylum and Hospital, consulting orthopedic surgeon to the Quincy (Mass.) Hospital, the Providence Hospital, Holyoke, and the Choate Memorial Hospital, Woburn, aged 55, died, October 5, of arteriosclerosis.

Charles Thaddeus Souther, Cincinnati, Medical College of Ohio, Cincinnati, 1902, member of the Ohio State Medical Association and the Western Surgical Association, fellow of the American College of Surgeons, past president of the Cincinnati Academy of Medicine, served during the World War, aged 59, president of the staff of St. Mary's Hospital, on the staffs of the Bethesda Hospital and the Deaconess Hospital, where he died, October 11.

Ralph Gates Cressman of Stockton, Calif., Bennett College of Eclectic Medicine and Surgery, Chicago, 1905, served during the World War, at one time medical examiner for the United States Veterans' Bureau, aged 55, died suddenly, October 18, in St. Joseph's Hospital, of ulcer of the stomach with perforation and carcinoma of the pancreas.

Waller Hunn Nardin of Anderson, S. C., New York University Medical College, 1897, fellow of the American College of Surgeons, past president of the Anderson County Medical Society, formerly member of the school board and city council, on the staff of the Anderson County Hospital, aged 59, died, October 7, of coronary thrombosis.

William A. Ferguson, Moncton, N. B., Canada, McGill University Faculty of Medicine, Montreal, Que., 1884, past president of the Council of Physicians and Surgeons of the New Brunswick, fellow of the American College of Surgeons, American College of Hospital

EDWARD STARR JUDD, M.D., 1878-1935

for many years on the staff of the Moncton General Hospital, aged 74, died, October 2, of pneumonia.

Herbert Arthur Breyfogle, Kansas City, Mo., Rush Medical College, Chicago, 1905, member of the Missouri State Medical Association, served during the World War, at one time member of the state board of health, on the staff of St. Luke's Hospital, aged 57, died, October 11, of coronary sclerosis.

Charles Jefferson Simmons of Lawrence, Kan., Bellevue Hospital Medical College, New York, 1885, formerly lecturer on principles of surgery and adjunct professor of general surgery, University of Kansas School of Medicine, aged 77, died, October 20, of peritonitis following a ruptured appendix.

George Marven Cady of Owego, N. Y., University of the City of New York Medical Department 1887, since 1891 trustee and since 1920 on the staff of the Robert Packer Hospital, Sayre, Pa., since 1921 member of the board of visitors of the Elmira Reformatory, aged 70, died, October 10.

Thaddeus Louis Szlapka, Shorewood, Wis., University of Pennsylvania Department of Medicine, Philadelphia 1914, served during the World War, formerly assistant clinical professor of medicine, Marquette University School of Medicine, aged 44, died, September 29, of pneumonia.

Jethra Hancock, Louisville, Ky., Hospital College of Medicine, Louisville, 1905, member of the Kentucky State Medical Association, served during the World War, director of the bureau of venereal diseases, state board of health, aged 60, died, October 4

Charles George Koehler, Brooklyn College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882, member of the Medical Society of the State of New York, aged 77, died, October 30, of chronic myocarditis and bronchitis

Frank Albert Phillips, Pasadena, Calif., Bennett College of Eclectic Medicine and Surgery, Chicago, 1886 College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1891, aged 69, died, September 10, of tuberculosis

Nathan M. Friedman, Boston Medizinische Fakultät der Albertus-Universität, Königsberg, Prussia, 1906, Tufts College Medical School, Boston 1909, member of the Massachusetts Medical Society, aged 51, died, October 3, of carcinoma of the right lung

Albert Durham, Tuxedo N. C., University of the City of New York Medical Department, 1891, served during the World War, for many years on the staff of the Bloomingdale Hospital, White Plains, N. Y., aged 71 died October 27, of heart disease.

Philip Reginald Fox * Madison, Wis., Rush Medical College, Chicago, 1890, fellow of the American College of Surgeons, on the staffs of St. Mary's and Madison General hospitals, aged 68, died, October 2, of carcinoma of the rectum

Frank Llewellyn Durgin, Winnebago Minn., Western Reserve University Medical Department, Cleveland, 1882, member of the Minnesota State Medical Association aged 83, died, September 23, of chronic myocarditis and arteriosclerosis

Julius Morris Abelio, Los Angeles, College of Physicians and Surgeons of Chicago, 1892 formerly on the staff of the Mount Sinai Hospital, Chicago, aged 72, died, November 8 in the Cedars of Lebanon Hospital, of bronchopneumonia

Francis John Higgins * East Providence, R. I., Tufts College Medical School Boston, 1921, on the staffs of St. Joseph's Hospital and the Homeopathic Hospital, Providence, aged 41, died, October 3, of cerebral hemorrhage

John F. Hargan, Mound City, Ill., University of Louisville (Ky.) Medical Department, 1891, member of the Illinois State Medical Society, aged 71, died, September 29, in St. Mary's Infirmary, Cairo, of cerebral hemorrhage.

William J. Gundelach * St. Louis, Washington University School of Medicine, 1890, University of Pennsylvania Department of Medicine, Philadelphia, 1891 aged 67, died, September 29, of chronic interstitial nephritis

Harry Kepler Gorsuch, Baltimore, College of Physicians and Surgeons, Baltimore, 1889, member of the Medical Surgical Faculty of Maryland, for many years city coroner, aged 66, died, October 9, of angina pectoris

William Hampton Matchett, Greenville, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899, aged 58 died, October 3, in the Greenville Hospital, of chronic nephritis and hypertension

Hazleton H. Stallard, Pikeville, Ky., Columbus Medical College, 1890, member of the Kentucky State Medical Association aged 70, died, September 24, in the Methodist Hospital, of diabetic gangrene.

Frank Gale Renshaw, Pensacola Fla., University of Louisiana Medical Department, New Orleans 1879 member of the Florida Medical Association, aged 79 died September 11, of acute leukemia

Adolph Herman Nahman * San Francisco Northwestern University Medical School, Chicago 1909 fellow of the American College of Physicians, aged 58 died, September 21, of spongioblastoma.

Jacob B. Spangler, Mechanicsburg, Pa., Jefferson Medical College of Philadelphia, 1886 member of the Medical Society of the State of Pennsylvania, aged 72 died October 7 of arteriosclerosis

Leonida Olivieri, Stockton, Calif. Regia Università di Genova degli studi Facoltà di Medicina e Chirurgia Italy, 1884 aged 73, died, September 10, in St. Joseph's Hospital of arteriosclerosis

Charles J. Fazenbaker, Western Port, Md. National Normal University College of Medicine Lebanon, Ohio, 1896, aged 68 died September 22 near Laurel, Md., of chronic myocarditis and epilepsy

George White Griswold, Alma Center, Wis., Milwaukee Medical College, 1910, served during the World War, aged 49 died, September 17, of angina pectoris, arteriosclerosis and pyelitis

Ward Irving Huber, East Cleveland, Ohio, Western Reserve University Medical Department, Cleveland, 1912 aged 51, died, October 3, of chronic nephritis, myocarditis and pneumonia.

Fred Xenophon Lilly, Jumping Branch, W. Va., University of Louisville (Ky.) Medical Department, 1910 aged 49, was killed, September 21, when he was struck by an automobile

Willard Daniel Arnold, Spokane, Wash., Rush Medical College, Chicago, 1895, member of the Illinois State Medical Society aged 63, died September 17, of cerebral hemorrhage.

Morton Harley Lee, Bearden, Tenn., Southern Medical College, Atlanta, 1889 past president of the Knox County Medical Society, aged 79, died, October 3, of angina pectoris

James Henry Barry, Boston Tufts College Medical School, Boston, 1896, member of the Massachusetts Medical Society, aged 65 died, September 23, of arteriosclerotic heart disease.

Susan Sharpe Waddell, Tsinan, Shantung, China, University of Pittsburgh School of Medicine, 1919, medical missionary, aged 40, was killed, October 15, presumably by bandits

Arthur Humphrey Wood, Providence, R. I., New York Homeopathic Medical College and Hospital, 1889, aged 74, died, September 28, of angina pectoris, and arteriosclerosis

John Lavell Reeve, Lake Nebagamon, Wis., Queen's University Faculty of Medicine, Kingston, Ont., Canada 1882, aged 74, died, August 15, of myocarditis and coronary sclerosis

William Wallace Carleton, Waterloo, N. Y., University of Buffalo School of Medicine 1901, served during the World War, aged 56, died, October 15, of coronary thrombosis

Samuel Floersheim * Los Angeles, Bellevue Hospital Medical College, New York, 1898, aged 58 died, October 4, in the California Hospital, of ruptured ulcer of the sigmoid

Joseph Edward Clagett, Hamilton, Va., Maryland Medical College, Baltimore, 1910, member of the Medical Society of Virginia, aged 55, died, October 26, of angina pectoris

Duncan Aeneas MacGregor, Barry's Bay, Ont., Canada University of Bishop College Faculty of Medicine, Montreal, Que., 1904, aged 58, died, October 15, of septicemia

Howard Roeder Swayne, Pittsburgh, Jefferson Medical College of Philadelphia, 1889, aged 72, died, September 29, in the Mercy Hospital of chronic cardiovascular disease

Robert Scott Dinsmore, Walla Walla, Wash., College of Physicians and Surgeons, Keokuk, Iowa, 1878, aged 81, died, August 28, of coronary sclerosis and angina pectoris

Bransen Kemper De Voe, Albany, N. Y., Albany Medical College 1904, member of the Medical Society of the State of New York, aged 63, died, October 3, of myocarditis

Tillman Wesley Gee, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1932, aged 30, died, October 9 of hypertensive cardiovascular disease.

Albert Edward Patterson, Plymouth, Mich., Detroit College of Medicine 1901, served during the World War, aged 65 died, September 13, of cerebral hemorrhage.

Howard Messenger Shaw, Ashland Ore., McGill University Faculty of Medicine, Montreal Que. 1895, aged 64, died, September 12, of carcinoma of the lung

Thomas Frederick Madden * Fresno, Calif., Cooper Medical College, San Francisco, 1904, aged 55, died, September 8, of streptococcal cellulitis of the face

James Robert Lockhart, Sherard, Miss., University of Nashville (Tenn.) Medical Department, 1899, aged 63, died, October 5, of carcinoma of the stomach

Ella Welch Ashley, Ohio, Toledo Medical College, 1894, for many years member of the county board of health, aged 72, died, September 23, of arteriosclerosis

Charles William Stolz, New Albany, Ind., Central College of Physicians and Surgeons, Indianapolis, 1904, aged 73, died, October 14 of arteriosclerosis

Paul F. Deford, Pasadena, Calif., University of Maryland School of Medicine, Baltimore, 1889, aged 67, died, September 21 of coronary sclerosis

John Lemuel Thornton * Warrenton, Va., Jefferson Medical College of Philadelphia, 1924, aged 40, died, October 7, of pulmonary tuberculosis

M. Hugo Rosenheimer, Milwaukee Milwaukee Medical College, 1908, aged 50, died, September 29, in Rochester, Minn., of hypertension and uremia.

Correspondence

THE COMMITTEE AGAINST INFANTILE PARALYSIS AND THE GEORGIA WARM SPRINGS FOUNDATION

To the Editor—In its simplest definition, the Georgia Warm Springs Foundation, Inc., is an organization engaged in "fighting infantile paralysis" in the United States.

Any comprehensive campaign directed to the problems created by this disease is naturally divided into three main subdivisions, namely, (1) research toward successful methods of prevention of and immunization against infantile paralysis, (2) after-treatment, to do everything possible to raise the general standard of methods and facilities used in the after-treatment of infantile paralysis for those who have been left with muscle impairment or deformities, following the acute stage, and (3) rehabilitation and employment. Supplementing and following the work of the orthopedic surgeons and hospitals in bringing about whatever physical restoration is possible, there comes the vital problem of giving to those with a residual handicap such specialized education and training as will enable them to hold a useful place in life and to become economically independent.

Of equal importance is the problem of educating those who employ large numbers of persons to the philosophy of giving an equal opportunity, in appropriate occupations and without prejudice or favoritism, to those who have visible handicaps (orthopedic cripples). It has been proved repeatedly that a physical disability is a minor matter whenever there is real ability, and yet there is all too often an almost automatic ruling out of consideration of persons who use crutches or braces. It has not been sufficiently brought home just what modern transportation does to open the door of opportunity to the crippled workman or executive in the present age, as contrasted to what the disability might have meant 100 years ago. A self-respecting person with the crippling handicap asks or wants no pity. A crippled person is in exactly the same position as a golfer who has to accept a handicap to play in a foursome. It may even make the game of life more interesting, as indeed it does for many of the golfers. The truth is that every member of the golf foursome has some kind of a handicap, if not the one on his score. The same is true of the relationship of people to life, but the crippled person often has to face an unreasonable prejudice, solely because his handicap is visible, whereas the next person who applies for the job may have a much more serious handicap, which is not visible and therefore goes, for the time being, unnoticed.

It is the purpose of the Georgia Warm Springs Foundation to cooperate with those existing agencies—medical and lay—which as a part of their programs contribute directly to the fight against infantile paralysis. It is the purpose of the foundation to approach this in a broad educational manner, without any attempt at centralized control or bureaucratic methods. The name "Georgia Warm Springs Foundation, Inc.," has its origin in the fact that the beginning of the work of this organization was the creation of an institution or hospital at Warm Springs, Ga., devoting its energies to the after-treatment phase of infantile paralysis for a limited number of patients. Out of this small beginning and through public interest and support, as well as through private donations, it has been possible to create a broad program intended to be helpful to the whole cause. Perhaps today the work of the foundation would be better defined under the title "Infantile Paralysis Foundation." It is possible that some day the name of the organization will be changed. In the meantime it is simply a heritage from the manner in which the present program obtained its origin.

A brief outline of the two birthday balls for the President may be in order. The National Committee for the Birthday Ball for the President, under the chairmanship of Mr. Henry L. Doherty, organized parties in a great number of communities in all parts of the United States on the President's birthday, Jan. 30, 1934, with the purpose of presenting the resulting funds to the Georgia Warm Springs Foundation for the furtherance of its program of fighting infantile paralysis. The committee, under the same chairman, conducted a second ball, Jan. 30, 1935, with a program calling for 30 per cent of the funds to be allocated to preventive research and 70 per cent to remain in the local communities for the furtherance of their own programs of after-treatment of infantile paralysis.

On May 9, 1934, there was received from the National Committee for the Birthday Ball for the President the sum of \$1,003 030 08.

It is to be noted that, out of this fund, half of the beds at Warm Springs (which total 100) are being supported in full or in part in order that a substantial proportion of the registration may be made up of charity and semicharity patients.

It is not part of the present purpose of the trustees to enlarge the capacity of the institution at Warm Springs, it is felt that the funds which have been entrusted to us through the generosity of the public and private donors can better be utilized in emphasis on a coordinative educational program. The objective is to have the 100 patients at Warm Springs represent a geographic distribution of the whole country and be a cross section of the problem presented by poliomyelitis as to age, sex, economic condition and degree of physical impairment. The Orthopedic Advisory Committee is assisting in the selection and admission of these 100 patients for treatment and furtherance of the educational and coordinative work of the institution at Warm Springs.

The 1935 birthday ball enabled the national committee to turn over, through the President, the sum of \$242,286.82 for medical research work in prevention and immunization. The disbursement of this sum is the responsibility of a special body created for that purpose, namely, the President's Birthday Ball Commission for Infantile Paralysis Research. This lay commission is assisted in its decisions as to the research projects to be supported by a medical advisory board of three doctors, none of whom are themselves engaged in research work in anterior poliomyelitis.

There are a total of six subdivisions of the foundation's work, which are creations or outgrowths of the work of the Georgia Warm Springs Foundation. They are the President's Birthday Ball Commission for Infantile Paralysis Research, the National Committee for the Birthday Ball for the President, the Employment and Rehabilitation Advisory Committee, the Committee for Public Information, the Orthopedic Advisory Committee and the foundation's institution at Warm Springs, Ga. Two of these, the Employment and Rehabilitation Advisory Committee and the Committee for Public Information, are new and in the process of formation. Four medical groups, between which and these subdivisions there exists a coordinative relationship, are playing a most important part in fighting infantile paralysis. These are (1) the American Medical Association, (2) the American Orthopedic Association and the American Academy of Orthopedic Surgeons, (3) the American Pediatric Society and the American Academy of Pediatrics and (4) the United States Public Health Service and the National Institute of Health.

ARTHUR CARPENTER, New York.

Executive Director, The Committee Against Infantile Paralysis, sponsored by the Georgia Warm Springs Foundation, Inc.

MORTALITY RATE IN TUBERCULOSIS

To the Editor—What is the present mortality rate of tuberculosis in the United States compared with twenty years ago? How does it rank as to the cause of death compared with heart disease and cancer? Please omit name
M D Ohio

ANSWER.—The latest available 'Mortality Statistics' of the United States Bureau of the Census are those for the year 1932 which give the mortality rate per hundred thousand of estimated population in the registration area of continental United States for tuberculosis of the respiratory system as 56.4, and for other forms of tuberculosis as 6.4. For the year 1910 the mortality rate of tuberculosis of the respiratory system is given as 136, and for other forms of tuberculosis as 24.3. The mortality rate per hundred thousand of estimated population in the registration area in continental United States for the year 1932 for diseases of the heart is given in this volume as 209.2 and for cancer and other malignant tumors as 102.2.

USE OF PERIODIC TUBERCULIN TESTS

To the Editor—The pediatrician who cares for my children always gives them a tuberculin test twice yearly. They object strenuously to this and I wonder whether it is necessary. Please omit name
M D Oregon

ANSWER.—The pediatrician who administers the tuberculin test twice yearly for the children under his care has the modern point of view of tuberculosis control. He has two objects in mind: the first is to learn whether the child has become associated with any open case of tuberculosis during the previous six months. He is aware of the fact that there are still many persons who have tuberculosis in a communicable form who are unsuspected of having the disease and that any child may come in contact with such a case and take tubercle bacilli into the body. He also knows that the positive tuberculin test is the first evidence of a tuberculous lesion which any phase of the examination will reveal and that in most cases this is the only evidence available over a considerable period of time and that it may remain the only evidence of the presence of tuberculosis in the body during the lifetime of the individual. Since it is true that a single contact with an open case of tuberculosis may result in a positive tuberculin reaction, one must keep in mind that the association with the open case may have continued. The first and the most important step in the treatment of tuberculosis of the child, even though it is manifested only by the positive tuberculin reaction, is to stop further exposure, that is, to prevent at the earliest possible moment any more tubercle bacilli from entering the body. Convincing evidence has accrued to support the view that the longer exposure to tubercle bacilli is allowed to continue the greater the chances of the child's falling ill from a clinical form of tuberculosis at some later time in life. The pediatrician is desirous of protecting the children under his care from such occurrence, and therefore he administers the tuberculin test periodically to make sure that such exposure is not occurring.

The second object which the pediatrician has in mind is to detect tuberculosis as soon as possible after it develops. There is a small percentage of infants and children who develop primary tuberculosis, tuberculous pneumonia or meningitis soon after the first infection is established. Wallgren (*J Pediat* 5:291 [Sept.] 1934) has shown that these very destructive forms of tuberculosis occur most frequently within three months from the time the first infection type of disease results in sensitization of the tissues. While they are reinfection forms of tuberculosis of endogenous origin there is no way to prevent them after the first infection type of disease is established and they usually do not respond well to treatment. Even though they occur in only a small percentage of all infected infants and children, the pediatrician must constantly keep these conditions in mind in all children who have recently become infected and who react positively to the tuberculin test. The knowledge that the tuberculin test has been positive may aid him greatly in establishing an early diagnosis if such a child falls acutely ill since as primary disease, tuberculous pneumonia and meningitis progress the tissues may become so desensitized that they no longer react positively to the tuberculin test.

Moreover the pediatrician is aware of the remote dangers from the tuberculous infection that results in the positive tuber-

culin test. He knows that the sensitization of the tissues to tuberculo-protein is a liability; he also knows that, while the first infection foci of tuberculosis usually do not cause any significant illness, they usually harbor living and virulent tubercle bacilli over long periods of time and that if such bacilli are set free into the adjacent tissues or into the blood stream they are likely to produce reinfection, clinical forms of tuberculosis in the bones and joints, kidneys, lungs and other parts of the body. Moreover he knows that exposure to exogenous sources is dangerous, and therefore he is in a position to instruct the parents to keep such children, so far as it is possible, from contact with open cases of tuberculosis.

The pediatrician who administers the tuberculin test periodically among the children of his clientele and constantly instructs the parents concerning the prevention of the first infection type of tuberculosis and recommends the proper procedures for those who have already become contaminated with tubercle bacilli is practicing the best method of tuberculosis control. In fact, Sir Robert Philip (*Brit M J* 1:43 [Jan 10] 1931) of Edinburgh has used this procedure for more than three decades with excellent results. Tuberculin administered in the proper dosage every six months to children reacting negatively to the test results in no harm, nor does it sensitize the tissues. Therefore it is an excellent procedure and the physician who administers it is practicing the most modern phase of diagnosis in tuberculosis. Since the children in this particular case object strenuously to the test, it might be well to substitute the percutaneous method of administration as described by Beatrice R. Lovett (*The Percutaneous Tuberculin Reaction Am J Dis Child* 37:918 [May] 1929) or the tape test described by Ernst Wolff (*Am Rev Tuberc* 27:308 [March] 1933). These tests do not require the use of a needle or any instrument and are about as accurate as the epidermal test of Pirquet or the intradermal test of Mantoux. In any event, the pediatrician should be permitted to continue the periodic testing of the children.

INTERPRETATION OF TUBERCULIN TEST

To the Editor—The other day I attempted a tuberculin test on a patient whom I suspected of having tuberculosis. As there was some of the solution left and being curious I tried the test on myself. I used the tablets Tuberculin P P D put out by Sharpe & Dohme. Much to my surprise the next day I showed a four plus skin reaction together with a marked systemic reaction. I am 40 years of age and have always been perfectly healthy and have never suspected that I might have tuberculosis. I should like to know your opinion of this positive reaction of the tuberculin test on myself. I should also like to know your opinion as to its value in making a diagnosis in suspected cases of tuberculosis. Please omit name
M D, Nebraska

ANSWER.—From the description of the reaction, one wonders whether it was due to tuberculin or pyogenic micro-organisms that entered the skin through the needle puncture. The tuberculin reaction is not interpreted as four plus unless there is evidence of necrosis, which is usually followed by sloughing of the tissues. Such evidence usually is not available in such a short period of time. If the directions for administering Purified Protein Derivative were carefully followed when the first dose was administered there should have been no systemic reaction and no necrosis and sloughing at the site of injection. If the first dose has caused no reaction, the second dose almost never results in necrosis and sloughing or a systemic reaction. Therefore if the reaction described was due to tuberculin, it would seem that a larger amount was administered than is usually prescribed.

A positive tuberculin reaction at any age provides one with two facts: first that the reactor has been exposed either directly or indirectly to a person or an animal suffering from tuberculosis or acting as a carrier or disseminator of tubercle bacilli, second that tubercle bacilli have gained entrance to the body and have set up at least one primary focus. Among persons who have reached the age of 40 years, one must expect to find a rather high percentage reacting positively to the tuberculin test. When such persons were infants and children little was done in any community to protect them against tubercle bacilli of both the bovine and the human type. Tuberculin testing of cattle had not reached significant proportions, nor was pasteurization of dairy products extensively practiced. Tuberculous patients for the most part remained in their homes and communities with little or no attempt at isolation and almost no successful treatment; thus they transmitted tubercle bacilli to infants and children. Therefore, the wonder is that any infant or child escaped contamination.

The tubercle bacilli that resulted in the first infection of tuberculosis may have entered the body and set up this disease forty years ago. Again they may have entered as recently as

as from three to seven weeks before the test was administered or at any intervening time. Regardless of the age in life that tubercle bacilli enter the body, the defense mechanism, consisting of neutrophils, monocytes, lymphocytes, connective tissue cells and so on, quickly focalize and surround them. A fibrous capsule usually is thrown up around these foci of bacilli, and lime may be deposited in the small caseous center of the tubercle. This may later extend into the capsule, and thus a true limestone wall surrounds the bacilli. In fact, in about 25 per cent of the cases a wall of true bone develops around the foci of tubercle bacilli. All this transpires in the bodies of human beings who become infected without causing significant illness, and therefore the individual whose body possesses such lesions usually is not aware of their presence until some special examination is made that detects them. Within about three to seven weeks after tubercle formation begins, the tissues of the body have become sensitive to tuberculinoprotein, and this sensitization probably persists as long as the tubercle bacilli remain alive in the body.

Thus the positive reaction indicates the presence of foci of the first infection type of tuberculosis somewhere in the body. Unfortunately, it does not determine whether the reinfection destructive type of disease has developed but since this type usually occurs only in the bodies of persons who react positively to the tuberculin test, every person with such a reaction should have adequate examination to determine whether the disease exists in a destructive form.

One usually looks first to the chest for the tuberculous lesions, whether they are of the first infection or the reinfection type. The x-ray film is far superior to any other phase of examination in detecting the location of such foci, but in the first infection type tuberculosis the lesions are often so small that they do not cast shadows that can be visualized on the film. Therefore, when the film shows no evidence of the location of the lesion it does not in any way invalidate the tuberculin test since this test detects microscopic lesions as well as gross ones, whereas the x-ray film detects the location of only macroscopic lesions. However, when the chronic reinfection type of tuberculosis develops in the lungs to such an extent that it jeopardizes the health of the individual, it is usually sufficiently large to cast a shadow that can be seen on the x-ray film. Such shadows can usually be detected two or three years before the lesions cause any significant symptoms or abnormal physical signs.

The fact that a person who reacts positively to the tuberculin test appears well and has experienced no symptoms is insignificant. Such an individual may have definitely progressive reinfection type tuberculosis. Indeed all persons who suffer from moderately or far advanced pulmonary tuberculosis passed through such a stage when their health was good and their disease could have been detected by tuberculin and roentgen examination.

The great success of the veterinarian in controlling tuberculosis among the cattle of this country is due to the fact that he recognized the specificity of the tuberculin test and that he sought tuberculosis among animals that appeared healthy. It is not until tuberculosis is sought among human beings who appear healthy and treated before it causes illness that significant further strides will be made in the control of tuberculosis in human beings.

The fact that the age of 40 years has been attained does not offer any assurance that clinical tuberculosis may not develop in the body. Although there is a popular belief that after middle life tuberculosis is a rare disease, the truth is that for the number of persons living beyond the age of 50 years the incidence of tuberculosis in a communicable form is higher than during any other age period in life.

In suspected cases of tuberculosis the tuberculin test is of great value. The degree of reaction probably is of no significance, but the test informs one with a high degree of certainty as to the presence or absence of foci of tuberculosis in the body. Whether these foci have anything to do with the symptoms or conditions causing one to suspect clinical tuberculosis must be determined by further examination, including x-ray films of the chest.

SCHOOL CHILDREN AND TUBERCULOSIS

To the Editor—When should children diagnosed as having pulmonary tuberculosis be excluded from school? Please omit name and address
M D Ohio

ANSWER.—In several states, laws exist that provide for the exclusion from school of children with tuberculosis. Formerly, tuberculosis was known to exist only when symptoms were present and abnormal physical signs could be elicited, for example, tuberculosis of the spine was not detected until knock-

ling or some other abnormal physical sign was evident and considerable pain was present. Likewise, pulmonary tuberculosis was not detected until symptoms, such as hemorrhage, cough, expectoration and weight loss, were present and abnormal physical signs, such as rales, could be heard over the area of disease. Such patients with pulmonary tuberculosis were nearly always spreaders of tubercle bacilli, and the individual was in need of drastic treatment when the disease was detected.

Modern methods of diagnosis now make it possible to detect pulmonary tuberculosis long before any symptom or any abnormal physical sign is present and long before the disease is communicable. Obviously, laws designed to exclude communicable cases of tuberculosis from the schools should not be applied in such cases.

While a good many school children, particularly in large cities, have the first infection type of tuberculosis, as indicated by a positive tuberculin test, and occasionally have deposits of calcium, which cast shadows on the x-ray film, it is particularly fortunate that school children who have not reached the high school age rarely have the reinfection form of tuberculosis. The first infection type of tuberculosis usually is not communicable in school children younger than the high school age. While it is true that, when the first infection type of disease is seen in the pneumonic stage, one may recover tubercle bacilli from the gastric contents in a fair percentage of the cases (Poulsen, Valdemar, Jensen, K. A., and Husted, E. The Demonstration of Tubercle Bacilli in Small Children with Pulmonary Tuberculosis, *Am J Dis Child* 37 900 [April] 1929; Willis, H. S. *Tr Nat Tuberc A*, 1933, p 135; Nalbant, J. P. *Am Rev Tuberc* 29 481 [April] 1934; Gourley, Ina, *ibid* 29 461 [April] 1934). It is also true that such children rarely cough or raise sputum. Therefore bacilli are usually eliminated from their bodies through the intestinal tract, and where the sanitary conditions are good there is little or no danger of disseminating bacilli to others. Moreover, the first infection type of tuberculosis is seen in the pneumonic stage much more frequently in infants than in school children. Searches made for tubercle bacilli even in the gastric contents from children with calcifications in their lesions are rarely successful, therefore between the ages of 5 and 12 years the human body is unusually free from pulmonary tuberculosis of a destructive form and rarely do children of this age disseminate tubercle bacilli to others. Children with the first infection type of tuberculosis in this age period require no treatment other than to protect them against open cases of tuberculosis in their homes and elsewhere. Therefore there is no need to enforce the law that provides for the exclusion of tuberculous children with the first infection type.

If the term "tuberculous" were carried to the logical conclusion and the law were rigidly enforced, every child reacting positively to the tuberculin test would be excluded from the schools. While in some rural sections of the nation not more than 5 or 6 per cent of the school children react positively to the tuberculin test, at the same time in our cities, for example Chicago, approximately 30 per cent of the high school children have the first infection type of tuberculosis. Overenthusiasm in the exclusion of children from school because they react positively to the tuberculin test and have evidence of calcium deposits in the lungs or ribs is capable of great injustice to the children and serious harm to the cause of tuberculosis control in general.

In one small city where the tuberculin test was administered and the positive reactors had x-ray films made of the chest, approximately seventy children were excluded from school, of whom not more than one had the reinfection type of disease requiring treatment and was a menace to the other children. The remainder of the children excluded had the noncommunicable first infection type of disease with no treatment indicated. With such action taken against these children, it will become increasingly difficult to secure consent of parents to examine children at any age. Although the reinfection type of disease in a communicable form is extremely rare between the ages of 5 and 12 years, it does occasionally occur, and therefore examination of all school children with tuberculin, x-ray films and so on should be carried out, in order to detect this occasional case, as well as the first infection type.

As adolescence approaches, and thereafter, some of the children who have previously been known to have the first infection type of tuberculosis begin to show evidence of the reinfection type of disease. While this may develop in any part of the lung, it most often makes its appearance just beneath the shadow of the clavicle in one or both lungs. Usually such lesions do not cause cough, expectoration or any other symptom for a year or more after they can be detected by the x-ray film, so that their disease is not communicable. However, if by serial x-ray films or by other laboratory procedures, such

as the differential leukocyte count and the red cell sedimentation test, the disease is found to be progressive treatment should be instituted at once.

Exclusion from school should depend on the communicability of the disease and the necessity of treatment for the individual. This measure is rarely indicated before the high school age is reached but during this period the reinfection type of disease is more frequently seen. Therefore great care should be exercised to find children who have this type of disease in a progressive form, to isolate them before they spread bacilli to others, and to treat them while treatment is of some avail.

HAY FEVER POLLENS IN PENNSYLVANIA

To the Editor—In reading literature of various concerns manufacturing pollen extracts for use in hay fever I am not able to find two lists that agree as to which are the possible causes of August to frost hay fever in Pennsylvania. A composite of all the lists is as follows: short ragweed long ragweed redroot (pigweed) Russian thistle corn goosefoot (lamb's quarters) cocklebur mugwort, sunflower goldenrod burweed marsh elder sheep sorrel careless weed dock hemp plantains spiny amaranth and wormwood. Is it necessary to test a patient for all these pollens in a persistent case of hay fever? Please omit name.

M D Pennsylvania

ANSWER.—It is true that the literature regarding the various pollens that may cause August to frost hay fever in Pennsylvania seems somewhat confusing. However, careful reading of the literature of the various firms that manufacture pollen extracts for use in treating hay fever will bring out the unanimous fact that the main cause of August to frost hay fever in Pennsylvania is the ragweed family consisting chiefly of short or dwarf ragweed (*Ambrosia artemisiifolia*) and the giant or high ragweed (*Ambrosia trifida*). These two constitute the main cause of fall hay fever not only in Pennsylvania but throughout most of the section of the country east of the Rockies and including a large part of Canada. These ragweeds do not grow in Europe.

All the other weeds mentioned in the query are of distinctly minor importance or of no importance at all. However in cases in which relief does not follow the proper injections of ragweed pollen extract or the symptoms do not coincide definitely with the time of pollination of the ragweeds, it is well to search for some local weed other than the ragweeds as a possible or even probable cause of these unusual cases.

Next to the two ragweeds in Pennsylvania come cocklebur (*Xanthium commune*) and burweed marsh elder (*Iva xanthiifolia*). These two give off some pollen but not nearly as much as do the ragweeds. Marsh elder (*Iva ciliata*) blooms from July to September and is not important.

Pigweed belongs to the Amaranth family, which is very important in the Southern and Western states but of minor importance in Pennsylvania. The members of this group are rough pigweed (*Amaranthus retroflexus*) spiny amaranth (*Amaranthus spinosus*), tumbleweed (*Amaranthus graecizans*) and careless weed (*Amaranthus Palmeri*). These pollinate chiefly from July to September.

The wormwoods pollinate from the end of July to October and constitute the main cause of hay fever west of the Rockies, where they are as important in causing hay fever as are the ragweeds east of the Rockies. They are of practically no importance in Pennsylvania although they are found scattered in most parts of the United States.

The goosefoot family (*Chenopodiaceae*) is a very important cause of hay fever in the Middle West especially in the Dakotas and Colorado. This family includes *Chenopodium Kochia Atriplex* and *Salsola* whose most important member is Russian thistle (*Salsola pestifer*). Of these the lamb's quarter (*Chenopodium album*) may be of some importance in Pennsylvania.

The Plantain family is a minor cause of hay fever all over the United States and most of Canada. Its chief member is English plantain (*Plantago lanceolata*).

The Rumex genus of the buckwheat family is also of some importance in hay fever work. Sheep sorrel (*Rumex acetosella*) and yellow or curl dock (*Rumex crispus*) throw out a moderate amount of pollen. They are probably insect pollinated to some extent.

The hemp family is also of minor importance. It consists of hemp (*Cannabis sativa*) and hop (*Humulus lupulus*). These pollinate from July to August. Sunflower and goldenrod are insect pollinated at least for the most part and are unimportant. The pollen of corn is heavy and carried by the wind for only short distances for that reason. It therefore is important only to those who are in close contact with such pollen.

It will be seen from the foregoing that one will get the best results in the average case by injecting an extract of equal parts of giant and short ragweed. When this extract fails, search for some other pollen should be instituted.

THE VON RUCK VACCINE

To the Editor—A young woman patient of mine with tuberculosis has been recommended to the von Ruck Memorial Sanatorium at Asheville, N. C. What is their treatment? Is it approved by the A. M. A.?

M D, Kansas

To the Editor—I have had an inquiry concerning the use of von Ruck's serum in the treatment of tuberculosis. I have been unable to find any reference either in my quackery files or in the literature on this subject. Please give me any information that you have on the subject.

M D Texas

ANSWER.—From these and other inquiries that have come to THE JOURNAL, it would appear that the von Ruck vaccine is in for another period of exploitation. The treatment was first given publicity in 1912 by Dr. Karl von Ruck of Asheville, N. C., who was born in 1849 and was graduated in medicine in 1879. Dr. von Ruck died in 1922. In the period 1912-1915 Dr. von Ruck received wide publicity for his alleged discovery of a "tuberculin" which he asserted would produce immunity from tuberculosis in both man and animals. A preliminary announcement by Dr. von Ruck entitled "A Practical Method of Prophylactic Immunization Against Tuberculosis" was published in THE JOURNAL, May 18, 1912. Through political influence the United States Public Health Service was called on to investigate the von Ruck vaccine, and the newspapers published columns of laudatory matter on the subject. The results of the investigation were published in THE JOURNAL, June 21, 1913, in an article entitled "Animal Experiments With von Ruck's New Tuberculoproteins" by R. S. Cummings, M.D. The sum and substance of the investigations made under government supervision were that immunity was not produced by the vaccine but rather that the vaccine increased the susceptibility to tuberculosis. The newspapers gave practically no publicity to these unfavorable findings. The government studies were begun in Asheville at Dr. von Ruck's laboratory but were later transferred to the Hygienic Laboratory in Washington because Dr. von Ruck would not concede the right of the government's physicians to conduct an independent and controlled investigation and summarily interrupted their investigation in Asheville. It seemed apparent that Dr. von Ruck did not have sufficient confidence in his method to be willing to be investigated unless he supervised and controlled the investigation. These facts were discussed editorially in THE JOURNAL, Jan. 23, 1915. Further political attempts were made to boost the vaccine by printing at government expense as a Senate document a mildly favorable article by two physicians. Time has obviously sustained the findings of the Public Health Service physicians for, if the von Ruck vaccine possessed the virtues that were claimed for it, the scientific world would long since have adopted it.

SEDIMENTATION TEST IN TUBERCULOSIS

To the Editor—A colored woman aged 19 entered a hospital September 12 with unilateral tuberculosis apical with caseation and cavitation. As part of the routine examination a determination of the sedimentation time was attempted. Immediately after having been mixed with fresh 2.5 per cent sodium citrate solution the blood clotted. The attempt was repeated with the same results. Three control tubes were run on other patients with the same solution and these did not clot. The bleeding time of the patient is two minutes and the clotting time seven and one-half minutes. Her blood pressure is 105 systolic and 75 diastolic. Please inform me how this difficulty can be overcome and what effect it will have, if any, on the prognosis. The patient's hemoglobin is 60 per cent and red blood cell count 4,900,000. There is marked and rapid retraction of the clot. Aside from this and the tuberculosis the patient seems to be normal. Please omit name.

M D Tennessee

ANSWER.—The conditions reported seem to indicate an unusually high fibrin content in the blood plasma. Perhaps there is also a high globulin content and a proportionate decrease in albumin. Such a shift in the protein quotient with a high fibrin content is usually indicative of a poor prognosis. The fibrin content at any one time represents approximately the tissue destruction going on at that moment. In this case it is the acute caseation and is both acute and extensive. A subacute or a fibroid lesion although extensive in size, will not show a proportionate rise in fibrin.

The only way to perform this sedimentation is to try a more concentrated solution of citrate or use a smaller quantity of blood for the amount of citrate until a point is reached at which clotting will not result. A correction will have to be

made for the dilution by comparing it to the speed of cells falling in pure citrate. There is no other way to handle it. No doubt the results will be high, irrespective of the method used.

BRONCHITIS WITH BRONCHIECTASIS

To the Editor—I am reporting a case of probably a fetid chronic bronchitis with perhaps a mild degree of bronchiectasis. A man aged 57, had measles at the age of 18 and as a result of early exposure developed a heavy cold followed by prolonged coughing and with every symptom of an active tuberculosis for a few years following. Since that time the patient has enjoyed the average health and has lost no weight or time from work but has had a chronic cough with more or less of a gray brownish expectoration which varies according to the season of the year. The tonsils were removed years ago but more or less chronic throat and laryngeal trouble persists in association with the bronchitis. The teeth have been kept in good condition. The general condition is otherwise negative except for a chronic myocarditis which has developed in the last ten years and in my opinion is a result of the chronic infection of the chest. Beginning about five years ago a very fetid disagreeable odor of the breath developed and no remedy that I have tried has been of any avail. It is a very disagreeable condition with which I have to contend and evidently is quite repulsive to those about me (the patient being myself). I feel reasonably certain of the correctness of the diagnosis and my principal reason for writing you is to ask for any information concerning the treatment or at least some method by which I may be able to control or mask this condition. I have exhausted all information that I have with no avail. Since my breath is sufficient advertising I will ask that you withhold my name.

M D Nebraska

ANSWER—The information available does not permit of a complete diagnosis, without which suggestions as to treatment are apt to be of little value. Chronic bronchitis with a mild degree of bronchiectasis seems likely from the history. Clinically, this condition is often associated with a secondary to chronic sinusitis. It is assumed that pyorrhea is absent. Additional information required includes a special nose and throat examination to rule out ozena, and sinus roentgenograms to rule out chronic sinus infection. If these conditions are present, appropriate treatment should be of benefit. Special examinations directed to the lungs are important, particularly if ozena and chronic sinusitis are absent, these should include chest roentgenograms and aerobic and anaerobic cultures of fresh sputum apparently coughed up from the lungs.

DIET SENSITIVITIES

To the Editor—I have had two patients tell me that a doctor in this district has forbidden them drinking highballs made with ginger ale, advising them to substitute a club soda. Both patients are in excellent health. Is there any scientific medical opinion published on this subject?

ELLA A COUGHLAN M D, Orange N J

ANSWER—The physician who gave this advice is probably sensitive to ginger ale or else knows of some one who is. More and more physicians are now learning to fit the diet to the patient and not to hand it out ex cathedra. There is nothing truer than that one man's food is another man's poison, but a corollary of this is that because of food or a drink is poison to some unfortunate individual it is not necessary to tell ninety-nine other persons that they must not partake of it. The physician may ask a patient to watch and see whether some substances are toxic for him, but if they do not prove to be toxic why should the man go on depriving himself? If any diet fails to bring results in a few days or weeks, it should be discontinued.

TUBERCULIN TESTS

To the Editor—With reference to a tuberculin test in which the purified protein derivative was used intradermally what is the significance of elevation and central necrosis at the site of injection occurring after the prescribed limit of forty-eight hours? This condition appeared on the seventh or eighth day. The dose was 0.00002 mg.

ROBERT E. LEE M D Chicago

ANSWER—The correspondent does not state whether there occurred the usual reaction to tuberculin at the end of forty-eight hours, followed by the elevation and central necrosis at the site of injection on the seventh or eighth day. If the usual reaction occurred first, the later development probably represents a four plus reaction. In persons whose tissues are extremely sensitive to tuberculinoprotein, necrosis may result and evidence of it persist for many days or weeks. The necrotic tissue may slough out the reaction being comparable to the formation of a cavity in the lungs when a new focus of tuberculosis develops in the sensitized tissue.

However if there was no reaction at the end of forty-eight hours and the elevation and central necrosis were the first evidence on the seventh or eighth day there are two possibilities. One is the delayed reaction, which Pirquet described as a

"torpid" reaction (Frequency of Tuberculosis in Childhood, THE JOURNAL, Feb 27, 1909, p 675). While Pirquet's torpid reactions resulted from the epidermal test, they have been observed also when the intradermal test has been employed. However, the particular type of reaction described by the correspondent has not been reported by any one who has used purified protein derivative. The other possibility is that infection with pyogenic micro-organisms may have occurred through the needle tract.

LATENT SYPHILIS

To the Editor—A white man aged 29 contracted syphilis nine years ago. One month after the appearance of the chancre treatment was begun consisting of daily mercury inunctions for eighteen months and neosarsphenamine once weekly for eight weeks at a time over a period of two years with alternating rest periods varying between two weeks and a month. I am unable to ascertain the dosage of neosarsphenamine. The patient became Wassermann negative after several months, and about eight subsequent tests taken for the following two years remained negative. The first Wassermann reaction since then taken recently was 3 plus. What therapy would you advise? Please omit name.

M D New York

ANSWER—If a repetition of the Wassermann test still proves positive, the case should be treated as one of latent syphilis. Iodides and bismuth or mercury compounds should be administered first, followed by one of the arsphenamines. Treatment will depend on the results of subsequent serologic tests and a spinal fluid examination.

FRACTURE OF THE TIBIA

To the Editor—Kindly tell me the best way to treat a fracture of the tibia which extends into the knee joint. There is no displacement. When should passive movements be started? When active movements? When weight bearing?

M D Minnesota

ANSWER—If there is no displacement, fracture of the tibia extending into the knee joint should be treated by balanced traction and overhead suspension, with early active motion. There should be no hurry for passive motion. Adequate immobilization should be continued until union has occurred and it is probable that movement will take care of itself. Protective weight bearing with the use of a caliper brace and crutches may be started usually at the end of from eight to ten weeks. Böhler's clamp and the Forrester clamp and open operation are evidently not required in the case described.

ARTIFICIAL PNEUMOTHORAX IN TUBERCULOSIS

To the Editor—In an answer to a query on the treatment of tuberculosis (THE JOURNAL, September 7 p 818) the following statement is made: "In every case of minimal progressive pulmonary tuberculosis which is unilateral artificial pneumothorax should be instituted, since it is the only method of bringing about adequate rest of the diseased part. Lying in bed gives the lung but little rest. Lying in bed for a long enough time however will give the lung enough rest and increase the bodily resistance sufficiently to heal the disease in most incipient cases. This is no argument against the proper use of artificial pneumothorax which I have found most valuable in many cases but I do not believe that any one is justified in making the dogmatic statement that pneumothorax should be used in every case of minimal, progressive unilateral pulmonary tuberculosis."

Although artificial pneumothorax is a comparatively safe procedure, many complications occur even in the best equipped tuberculosis hospitals, and if this treatment should be attempted everywhere, often without x-ray control it is very likely that more harm than good would be done.

The patient under discussion was given only three months of rest treatment an entirely inadequate length of time for the healing of any active progressive tuberculous lesion though it is granted that if the patient must get up in three months the danger of relapse is less with a good pneumothorax than without it. It is probable that roentgen examination would have shown that the disease was in a more advanced stage than was suspected from the physical signs and that pneumothorax was indicated. Nevertheless the fact remains that some of the best cures of tuberculosis are made with the old fashioned rest treatment continued for a sufficient length of time. To determine what constitutes a sufficient length of time in the individual case is one of the most difficult tasks of the physician and the roentgen observations, physical examination, symptoms and laboratory tests are all to be taken into consideration. After the activity of the disease has apparently subsided a few extra months of at least partial rest should be allowed for good measure.

It is true that general rest without pneumothorax or other effective collapse therapy is futile in many cases but the point to be emphasized is that it takes years to heal any definite tuberculous disease completely either with or without pneumothorax and the man who counts on pneumothorax to heal his tuberculous patients in a hurry is going to be disappointed. In the last analysis the recovery of a patient from tuberculosis, as from any other infectious disease depends on his forces of resistance. Rest together with proper food, good climate and so on is the best method available of increasing the patient's resistance to his disease and no doubt the good results obtained from rest treatment are due more to the raising of resistance than to the lessened movement of the lungs.

LEROY ELRICK, M D Denver

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Written examination for Group B applicants will be held in various cities throughout the country March 14. Book Notices

Policies and Procedures in Public Health Proceedings of the Annual Conference of the Advisory Council of the Milbank Memorial Fund Held on March 27 and 28 1935 at the New York Academy of Medicine Paper Pp 115 New York Milbank Memorial Fund 1935

This brief report of the proceedings of the annual conference of the advisory council of the Milbank Memorial Fund consists of summaries setting forth the principal points in discussions of round-table groups dealing with public health problems with health education, with tuberculosis, with population studies and with venereal disease. In addition, it contains a speech by Albert B Milbank one by Surg Gen Hugh S Cumming one by Dr Simon Flexner, and one by Hon Josephine Roche, assistant secretary of the treasury. Dr Cumming's address on public health and the medical profession will be of particular interest to physicians and so will the remarks of Miss Roche on economic security and health. Dr Flexner's remarks on scientific discovery and the public health constitute a dissertation on the theme taken from Dr William H Welch 'While public health is the foundation of the happiness and prosperity of the people and its promotion is recognized as an important function of government, how wide is the gap between what is achieved and what might be realized.' Miss Roche's remarks are largely in support of the social security program, which at the time this discussion took place was pending but which has since been enacted in the Social Security Act.

In view of the impression which has prevailed among physicians that the Milbank Fund has been committed to socialization of medicine, an impression that gained currency perhaps largely through the activities of Mr John Kingsbury, certain statements in this report are of particular interest. In the report of the round-table discussion on public health problems under the chairmanship of C E A Winslow, DPH, the following statement occurs as a part of the discussion of rural service for the promotion of maternity and infancy health in Cattaraugus County 'The operation of medical services under lay direction is never satisfactory. It was the belief, therefore of the members of the round table that the provision of medical care for maternity and infancy at public expense should be placed under the direction of a county health department.' Physicians will readily agree with the first sentence in the

excerpt just quoted but are much less likely to agree that it leads necessarily to the conclusion which immediately follows. Wise health officers who have learned that the public cannot be educated to distinguish between prevention and treatment will be exceedingly reluctant to have their departments thrust into the practice of medicine.

Perhaps the greatest interest of all attaches to the remarks of Mr. Albert Milbank, who has given evidence, since certain representations were made to him by the medical profession, that closer relationship between himself and the activities of the Milbank Fund may be reflected in a changed attitude on the part of the fund, as shown in the following excerpts from his remarks:

"You are doubtless aware, in a general way, of the experiments that are being conducted in various parts of the country under the auspices of professional groups and of medical societies to bridge the economic gap between those in need of medical care and those equipped to supply that care without however, resorting to compulsory contributory health insurance. Some of these activities are reaching a stage where their effectiveness may be profitably studied and evaluated."

"It is my hope that, after the new Medical Advisory Committee which your Chairman has been authorized to form has been organized, some way may be found for our Fund to cooperate with one or more of these professionally conducted experiments."

"There are other subjects, not related to medical economics, which can also be explored in collaboration with physicians whose primary interest is in the private practice of medicine but who have as well a very real interest in preventive measures. This common interest will form a natural point of contact between the Fund and the profession in the future as it has in the past and will serve to dissipate the erroneous impression that our Fund is chiefly, if not exclusively, concerned with the subject of the cost of medical care."

"Our Board of Directors has not endorsed compulsory contributory health insurance or any other plan to distribute the costs of medical care."

We have not sponsored any form of legislation, Federal or State, bearing upon this subject nor have we given, directly or indirectly, any financial support in furtherance of such legislation.

"The studies made by the members of our staff on this or any other subject in the field of public health, as broadly defined, will be made available to the various groups interested in that field but the Fund will not assume the role of advocate either in favor of or against specific solutions of the problems which are the subject matter of such studies."

"We will cooperate with the groups operating in the broad field of health—whether they be doctors, dentists, hospital managements, nurses, welfare organizations, or governmental agencies—to the extent that our cooperation is desired and to the extent that a basis of mutual helpfulness can be established within the resources at our disposal."

The large influence which voluntary foundations heavily endowed have acquired in the field of health makes them a real factor which must be reckoned with. The evidence that the point of view of the medical profession is gaining increased consideration at the hands of the Milbank Fund might be observed with profit by the directors and the executives of certain other foundations.

Apparatus and Technique for Roentgenography of the Chest. By Charles Weyl and S. Reid Warren Jr. Moore School of Electrical Engineering University of Pennsylvania. Cloth. Price \$5. Pp. 186 with 39 illustrations. Springfield Illinois & Baltimore Charles C. Thomas 1935.

The authors, feeling that the roentgenologist, being busy with the practice of his profession and keeping abreast of medical developments, has little time for a thorough study of physical principles, discuss the physical problems of chest roentgenography. The book is divided into four chapters and an appendix. The first chapter consists of a review of the physical phenomena underlying the production of chest roentgenograms. Available roentgenographic apparatus is discussed in chapter II with a presentation of the advantages and disadvantages of the various types. The quality and interpretability of the finished

film depends on the roentgenographic densities, contrast and sharpness. The effect of varying the controllable roentgenographic factors is discussed in chapter III. The experienced roentgenologist in most instances passes judgment on the quality of roentgenograms. The authors feel that a more accurate method of judgment can be carried out by the use of a densitometer. Chapter IV consists of a discussion of the scientific analysis of roentgenograms by means of various physical tests. For such analysis every roentgenogram should have impressed on it a roentgenographic record of a standard aluminum ladder and timing disk. A comparative densitometer and a standard density table are used in measuring the roentgenographic densities. An appendix on basic and elementary electrical principles has been added to the volume. Much of the material covered is common knowledge to experienced roentgenologists, who will probably find it cumbersome and time consuming to employ the rather complicated method of judging the quality of a roentgenogram recommended by the authors.

Traitement des fractures et luxations des membres. Par Jacques Leveuf, professeur agrégé à la Faculté de médecine de Paris, Charles Glrode et Raoul Charles Monod, chirurgiens des hôpitaux de Paris. Préface du Professeur Pierre Delbet. Second édition. Paper. Price, 30 francs. Pp. 447 with 314 illustrations. Paris: Masson & Cie 1935.

This treatise on fractures and dislocations is of an eclectic nature, as the authors confine themselves to a description of methods used by them, hence a bibliography and references to other methods have been omitted.

The first part of the book deals with fractures. The first chapter offers a discussion of general principles of treatment, including first aid, temporary immobilization of fractured limbs, final conservative or surgical therapy, and after-care. The advice to use sheets as hammocks in which patients with broken hips are suspended during transportation will probably not meet with approval in this country, where a board is preferred for efficient immobilization. Local anesthesia is advocated for reduction of fractures, but its technic is not described. In children, tribrom-ethanol anesthesia is being used. Spinal anesthesia is recommended for reduction of hip fractures. The technic of open reductions is described briefly, avenues of approach are discussed in general terms. Accompanying pictures are numerous but inadequate and without details. Many methods and splints popular in the United States are not mentioned such as Russell traction, Hodgen's leg splint, the Jones humerus splint and the well leg countertraction splint. Skeletal traction appliances are recommended but the technic has not been described. The ensuing thirteen chapters describe the treatment of fractures of various bones. The therapy of skull fractures has been entirely omitted. The treatment of dislocation has been allotted only sixty pages, forming the second part of the book. The scope of this book is the technical side of the treatment of fractures and dislocations. It may serve as a valuable manual for French students, better books are available in the English language.

Anesthesia in Dental Surgery. By Sterling V. Mead, D.D.S., M.S.-B.S. Cloth. Price \$6.50. Pp. 482 with 144 illustrations. St. Louis: C. V. Mosby Company 1935.

This is a good book and should prove valuable, particularly to undergraduate students and practitioners of dentistry. There are thirty-two chapters. The chapters on the history of general and local anesthesia are well written and will be useful for purposes of reference.

Anesthesia is essentially a clinical subject, and, while a foundation of general medical training is of prime value, one learns the art of anesthesia by practical experience. The author properly emphasizes the necessity of ample knowledge and experience before assuming the responsibility of administering either local or general anesthetic agents. Under the heading "Legal Responsibility" he says: "The right to administer an anesthetic, whether by a physician or a dentist, depends entirely upon the possession of the requisite knowledge, skill and experience. A dentist undoubtedly has the right to administer anesthetics in his practice if he is competent to do so. But a dentist has not the right to administer anesthetics unless he is familiar with their effects and can show his proficiency in this respect." In line with this declaration one may properly ask

two questions Should any one not competent to make an intelligent physical examination administer anesthetics? Or, again, Should any one administer a general anesthetic in his office, with only a nonmedical assistant, except perhaps, in cases of emergency? The rather widespread practice of dentists administering nitrous oxide in the office without a full knowledge of the patient's general condition and without the knowledge or means of meeting accidents incident to anesthesia, may be questioned In these times of good hospitals and expert anesthetists, the dentist may relieve himself of moral and legal responsibility by employing them It is no more a hardship on the patient to pay the ordinary fee for this service than the fee for other minor surgical operations

In skilful hands local anesthesia should reduce the use of nitrous oxide in dental practice to an irreducible minimum Except in cases of certain acute infections, young children and highly nervous individuals, who prefer a general to a local anesthetic, local anesthesia in oral surgery is simpler, safer and much more satisfactory, viewed from any angle In short the use of local anesthesia is advised only in the office, and general anesthesia only in the hospital

The use of sedatives preceding a general anesthetic is merely a part of the problem of responsibility The author meets these facts in a fair and honest manner One is compelled to disagree with the author in advising the use of nitrous oxide for children, especially young children surgeons and anesthetists will largely agree that ether is the anesthetic of choice for children On page 62, 93 per cent nitrous oxide and 7 per cent oxygen is recommended for children during the period of induction this is high even for an adult Attention is called to 'bridging' This is due to a lack of oxygen and should be regarded as a sign of danger

Chapters 18 to 32 cover the subject of local anesthesia in a comprehensive and satisfactory manner The entire text has been prepared with a good sense of fidelity to principles and details and should meet with a wide circulation

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern Die theoretischen Grundlagen und Möglichkeiten der röntgendiagnostischen Weichteiluntersuchung Von Dr. Adolf Zuppinger Assistent am Röntgeninstitut der Universität Zürich Fortschritte auf dem Gebiete der Röntgenstrahlen Ergänzungsband XLVIII. Herausgegeben von Prof. Dr. Grashey Paper Price 16 marks Pp. 99 with 46 illustrations Leipzig Georg Thieme 1935

The authors have made an elaborate study of the photographic and other physical bases underlying the possibility of demonstrating soft tissue detail in the roentgenogram The discussions on photographic emulsions the spectrum of diagnostic rays and the quantitative factors in the choice of diagnostic radiation are carefully elaborated The various other factors such as the choice of tubes, use of compression focus skin distance, use of filters for eliminating secondary radiation and the back fire radiation from the film mounting receive adequate attention Examples are given of roentgenograms of esophageal varices the soft tissues of the pharynx, the hypopharynx and the epipharynx A few pages are devoted to roentgenography of the mammary gland. Probably at this time the most important field for soft tissue radiography is the larynx and hypopharynx. The book is essentially technical and the explanations employ free use of higher mathematics Most radiologists have a practical experience in soft tissue demonstration and succeed to a degree. No doubt a thorough understanding of the principles put forth in this book will considerably amplify the field of soft tissue roentgenography

Disorders of the Blood Diagnosis, Pathology Treatment and Technique By Lionel E. H. Whitby C.V.O. M.C. M.D. Assistant Pathologist the Bland Sutton Institute of Pathology London and C. J. C. Britton M.D. Assistant Pathologist the Christchurch Hospital New Zealand Cloth Price \$7 Pp. 543 with 65 illustrations Philadelphia P. Blakiston's Son & Co. Inc. 1935

This book is a thoroughly up to-date presentation of hematology in both its scientific and its practical aspects It is lucid and simple in its manner of presentation and yet comprehensive enough in its scope to meet demands of almost any physician who should be interested in the blood and blood-forming organs It is adequately illustrated both in black and white and in colored plates It is well organized and exceedingly well

balanced Each subject is concisely but adequately treated and the important phases of the subject are well outlined The recent medical literature has been digested and assimilated and the reader will find a representative bibliography after each chapter The chapter on anemias in infancy and childhood is particularly well done Although it is a short chapter it is one of the most rational discussions of the subject that can be found in any textbook of hematology It is highly recommended as well balanced and authoritative and it should meet the needs of most physicians and students

Medicolegal

Silicosis Liability of Employer for Silicosis and Tuberculosis Contracted by Employee—Curtis operated a rock crushing machine for the Allen Gravel Company from April 1 to November 1930 During the dry times when the machine was being operated, large quantities of dust were created by the crushing of the rock, and employees who worked around this machine had their eyes, mouths, and noses affected thereby After Curtis had been working there a few months he developed a cough and experienced pains in the chest He finally procured medical attention and abandoned the particular employment However, he gradually grew worse, and the physician diagnosed his condition as tuberculosis brought on by silicosis Curtis sued his employer and obtained judgment, from which the employer appealed to the Supreme Court of Mississippi, division B

The rule is, said the court, that the employer must use reasonable care to provide a safe place for his employees to work. He is not an absolute insurer of the safety of the place, nor is he required to use the highest degree of care, but he should take reasonable precautions to make the place of work reasonably safe. The medical testimony, continued the court, was ample to show the dangers incident to the inhalation of silica dust and the general recognition of such dangers by the medical profession The public is interested in the preservation of health, and when others engage in business for profit which is dangerous to the health of employees, reasonable care should be taken to minimize the dangers The employer in this case, apparently, did not furnish his employees with respirators or other appliances to reduce the hazards incident to the employment. Where simple devices may be obtained, the court said, at a reasonable cost, the employer should procure them for the protection of his employees While the employer does not have to use all the latest devices that may be obtainable, he should exercise care to make the place safe, using reasonable care as a standard The jury was warranted, in the opinion of the court, in finding that there was negligence on the part of the employer The judgment for the employee was therefore affirmed—*Allen Gravel Co. v. Curtis (Miss.)*, 161 So. 670

Occupational Diseases Combined Sclerosis Attributed to Zinc Poisoning Not an Occupational Disease—The plaintiff in the course of his employment in the defendant's chemical plant was exposed to dust incident to the manufacture of zinc stearate dusting powder Attributing a combined sclerosis from which he subsequently suffered to the inhalations of zinc stearate dust, he sued his employer The trial court overruled the defendant's demurrer to the evidence and entered judgment for the plaintiff

On appeal, the Supreme Court of Missouri said that the question to be determined was whether there was evidence tending to prove that combined sclerosis—a degenerative process of the spinal cord—from which the experts testified that the plaintiff was suffering was an occupational disease under the Missouri occupational disease act An occupational disease, said the court, within the meaning of the act, as well as at common law, is one that is "peculiar" or "incident" to the work or process carried on. "Such a disease is defined to be a disease contracted in the usual and ordinary course of events, which, from the common experience of humanity, is known to

be incidental to a particular employment. It ordinarily results from long-continued work in the particular employment." *Lovell v Williams Bros* (Mo App) 50 S W (2d) 710. In the case here abstracted, the plaintiff testified that he was in good health when he went to work for the defendant. During the last six months of his employment he was engaged in making zinc stearate dusting powder. He coughed a great deal, 'emitting white stuff 'like talcum powder'." His throat and lungs were sore, his arms hurt, and his hands "were without feeling." His stomach became swollen and he could eat very little. He walked with difficulty and, after he left the defendant's employment, he could not move for a time. He was in a hospital twice for treatment and, according to the medical testimony, while there he was treated for locomotor ataxia. A physician specializing in mental and nervous diseases, called by the plaintiff, testified that the plaintiff was suffering from a nervous disorder consisting of a degeneration of the posterior columns of the spinal cord and known as combined sclerosis, which "could be due to absorption of zinc." He further testified, however, that he had never had a patient who had contracted combined sclerosis from zinc poisoning and did not know what amount of exposure or absorption would be necessary to produce the condition. He further testified that certain abnormalities which he found in the plaintiff and on which he rested his opinion that the plaintiff had combined sclerosis were cardinal symptoms of locomotor ataxia, such as an absence of the knee jerks, slight reaction of the pupils to light, and an ataxic gait. Another specialist in mental and nervous diseases testified that the plaintiff was suffering from combined sclerosis but did not definitely attribute the condition to any particular cause. Medical witnesses testifying for the defendant denied that the plaintiff had combined sclerosis and attributed his condition to locomotor ataxia.

In reviewing the evidence, the Supreme Court could find no testimony to the effect that combined sclerosis is an illness or disease peculiar or incident to the work or process carried on. In substantiation of this conclusion drawn from the evidence the court pointed out that in the report of the Committee on Standard Practices in the Problem of Compensation of Occupational Diseases of the Industrial Hygiene Section of the American Public Health Association (1931), containing a history of the extension of the workmen's compensation laws to include occupational diseases, there are many schedules of occupational diseases, but combined sclerosis is not listed in any schedule of any state or country. In the opinion of the Supreme Court, therefore, the trial court should have sustained the demurrer to the evidence because there was no testimony that the disease which the plaintiff contracted was peculiar or incident to his work. The judgment of the trial court was therefore reversed and the cause remanded for a new trial.—*IVolf v Mallinckrodt Chemical Works* (Mo) 81 S W (2d) 323

Workmen's Compensation Acts Strangulation of Pre-existing Hernia Attributed to Strain—The employee had suffered from an irreducible hernia for several years but had worked regularly and had experienced little trouble from his condition. He was employed as a craneman and during the process of repairing a broken crane he strained or twisted himself, a strangulated hernia developed and he died eleven days later. His widow instituted proceedings under the workmen's compensation act of Maryland. The state industrial accident commission denied compensation and from a judgment of the circuit court reversing the order of the commission the employer and its insurance carrier appealed to the Court of Appeals of Maryland.

The main controversy involved whether the injury was accidental within the meaning of the workmen's compensation act. A twist of a part of the human body, said the court, while engaged in the performance of some physical labor implies a sudden, unforeseen and unnatural bodily position or movement or muscular distortion that generally occurs without anticipation. The twist that was inflicted on the employee in the course of his work was not a natural result that could fairly be assumed to have been intended or expected. It was produced by a sudden, unintended movement of a heavy chain he was holding which caused the affected parts of his body to be forced or thrown from a normal state into a hurried unexpected and

unnatural or distorted position. If the lifting and holding of a heavy chain under difficult, insecure and unusual conditions should cause a rupture, the injury would, in ordinary acceptance, be described as an accident. The conclusions that the strangulated hernia, the court said, was the result of an accidental injury is supported by a number of decisions. *Schneider's Workmen's Compensation* (2 Ed) Sections 200, 335. The old hernia with which the employee was suffering for some years before the accident was not the hernia for which compensation was claimed. The compensable injury was a strangulated hernia which did not exist before the accident but which was directly caused by the accident. This strangulated hernia caused the employee's death and, where death ensues, there is no basis for the determination of the proportionate disability attributable to an old hernia and to the later strangulated hernia.

The court, therefore, affirmed the judgment of the circuit court for the claimant.—*Ross v Smith* (Md), 179 A 173

Dental Practice Acts Revocation of License Without Personal Service on Nonresident Licentiate—The board of dental examiners of West Virginia revoked the license of a dentist, presently residing in Ohio. The circuit court, on the ground that no notice of the revocation hearing was personally served on the dentist, set aside the revocation order on the condition that the dentist appear before the board on a certain day to defend the charges against him. Both the dentist and the board appealed to the Supreme Court of Appeals of West Virginia.

A revocation proceeding, said the Supreme Court of Appeals is in effect an in rem proceeding, and personal service on a nonresident is not requisite to jurisdiction, service of notice by publication is sufficient. The circuit court, therefore, erred in its ruling to the contrary. But, continued the court, the record in this case certified by the clerk of the circuit court contained no copy of any sort of notice to the defendant. The record did contain a recital that the hearing before the board was had "at the time and place appointed in the notice." The recital does not show to whom, or the manner in which, that notice was given. While the presumption arises that the members of the board, being public officers, performed their duty and that the notice referred to in the record was the notice required by the dental practice act, the Supreme Court of Appeals thought that the ends of justice would be better met by returning the case to the circuit court to afford the board an opportunity to supply for the record a copy of the notice referred to in the recital. The judgment of the circuit court was therefore reversed and the cause remanded.—*Board of Dental Examiners v Hedrick* (IV Va) 179 S E 809

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Clinical Experience with Derivative of Squill—Carr and Mayer studied the effect that a derivative of squill (scillonin) had on 104 patients having cardiac decompensation. They observed that the drug will produce the usual therapeutic and toxic effects of digitalis in the treatment of cardiac decompensation. In their experience, cardiac irregularities are likely to be the first signs of dangerous intoxication. Nausea does occur and may precede the appearance of cardiac irregularities. The nausea of scillonin intoxication is significant in that it appears to signify a more advanced grade of intoxication than that associated with the nausea of digitalis. When nausea and cardiac irregularities occur in the course of treatment with scillonin, the drug should be discontinued. Slowing of the cardiac rate to 60 or below is frequent with the successful use of scillonin. The onset of a rate as low as 60 is significant of the full therapeutic dose and calls for temporary discontinuance. A dose of from 8 to 12 mg of scillonin of standard potency as now provided, depending on the weight of the patient, may be given within four days to patients who are known to have taken no drug of the digitalis group within two weeks. If a prior course of scillonin or of some other drug of the digitalis group has been used with full therapeutic effect, the maximal dosage of scillonin should not be repeated within a month, but small doses may be given daily until the effect appears. The maintenance dose of scillonin is approximately 0.5 mg daily, but it must be adapted to the needs and response of the individual patient. A few patients have been kept on a small daily ration for three years or more. For small patients the daily maintenance dose is as low as 0.33 mg. Scillonin therapy is of advantage to certain persons who take digitalis with difficulty because of gastric distress early in the course of medication. It is not a substitute for digitalis in the presence of frank digitalis intoxication. Scillonin retains its potency over a long period. A supply in the authors' possession for about seventeen months proved as effective at the end of that time as the lots assayed recently.

Pulmonary Abscess and Pulmonary Gangrene—During the last ten years at Mount Sinai Hospital, Kline and Berger observed fifty-five cases of pulmonary spirochetosis (Miller-Vincent's infection of the lung) including thirty-nine cases of pulmonary gangrene, as well as twelve cases of bronchogenic pulmonary abscess and twenty-three cases of embolic pulmonary

abscesses. The embolic pulmonary abscesses were associated with areas of suppuration elsewhere in the body and were manifestations of generalized pyemia or bacteremia. Of the local bronchogenic pulmonary lesions, gangrene was observed more than three times as frequently as abscess. Although all the cases presented the clinical picture of so-called typical abscess of the lung, usually they were readily recognized by distinguishing characteristics as cases of gangrene and abscess, respectively. Of the thirty-nine cases of gangrene, thirty-two were in adults and seven in children. Of the twelve cases of bronchogenic abscess eight were in children and four in adults. Twenty-two cases of pulmonary gangrene followed an operation, usually performed under general anesthesia. Half the operations were on the oral cavity. This incidence emphasizes the danger of aspiration of infective material from the oral cavity. Of the patients with embolic pulmonary abscess, 96 per cent died. The mortality in cases of bronchogenic abscess was 58 per cent. In twenty-five cases of pulmonary gangrene with cavitation, the mortality was only 32 per cent. Mortality was 49 per cent in the whole group of cases including fourteen in which there was no treatment with arsenic or only one treatment when the patient was practically moribund (within four days of death).

Pyothorax Due to Fusospirochetal Infection—Flack reports three cases in which pyothorax accompanied severe pulmonary infection and in which fusospirochetal organisms appeared to constitute the important etiologic factor. The clinical course indicated that pyothorax associated with large numbers of fusospirochetal organisms causes certain clinical signs not encountered in the more common types of pyothorax. Diagnosis of this type of pyothorax should receive particular attention as the treatment should be directed along lines different from the medical and surgical treatment of the more common types of pyothorax. The establishment of a diagnosis of pyothorax resulting from fusospirochetal infection may precede the proper identification of the underlying infection involving the parenchyma of the lungs and may be of great value in the true estimation of the prognosis of the case. The diagnosis in the three cases was established only after the presence of fusospirochetal organisms in the empyema fluid was observed. Attention is called to the severity of the pleural pain and to the fact that the pain persists after the development of pleural effusion. The fetid odor of the pus obtained from the pyothorax in this type of infection is considered of diagnostic importance. The author believes that this type of acute pulmonary infection is much more common than a survey of the medical literature would indicate. In the differential diagnosis of cases of acute pulmonary disease, more consideration should be given to this type of infection.

Microcytic, Hypochromic Anemia in Childhood—Faber and his associates observed ten patients between the ages of 7 months and 2 years with anemia of the "nutritional" or "iron-deficiency" type, in whom gastric analysis after histamine

demonstrated a marked secretory defect free acid was absent in six and low in the other four, total acidity and volume were low in all cases. The blood showed marked hypochromia and microcytosis before treatment was begun. When soluble iron was administered in adequate amounts, there was a striking immediate response with reticulocytosis and increased size of red cells (transient macrocytosis) accompanying an increase in hemoglobin. This was followed by a decline of reticulocytes, by a return to an approximate distribution of cell sizes and by a continued rise in hemoglobin. A certain number of microcytes tended to persist. Twins who at the age of about 8 months had anacidity and anemia were reexamined seven years later. One still had nearly complete anacidity and a mild degree of anemia. The other was able to produce a moderate amount of acid (though probably less than the normal minimum) and still had microcytosis, but without hypochromia. On the basis of a comparison with the normal values for later childhood and adult life, the average presumptively healthy child in the latter half of the first year and for a few years thereafter has a mild hypochromic anemia. Available figures show that at least during the first and second years children secrete small amounts of gastric juice containing a relatively small amount of acid. It is probable that in this period of life the absorption of iron from ordinary diet is difficult and might be improved by administering soluble iron as a routine measure and by taking into account the acid-absorbing (buffer) effect of milk in regulating diet. The close resemblance between "iron deficiency" anemia of infancy and childhood and the hypochromic, microcytic anemia of adults is noted.

Lactic Acid Milk in Prevention of Summer Diarrhea—Scheuer reviews the incidence and mortality rate of summer diarrhea at the New York Foundling Hospital during the past twenty-five years (1910-1934). He observed that there was a persistence in the number of cases of summer diarrhea despite an adequate supply of clean milk with a low bacterial count. Because of the large number of marasmic cases resulting from summer diarrhea, powdered whole lactic acid milk mixtures containing only a total carbohydrate content of 7 per cent, 0.3 per cent lactic acid and a caloric value of less than 50 calories, per pound of body weight were fed to 403 infants during the summer months of 1931 to 1934. These infants were malnourished and were less than 6 months of age. Summer diarrhea did not occur among the 403 infants who were fed this type of lactic acid milk mixture.

Treatment of Trichomonas Vaginalis Vaginitis—The form of treatment that Smith has been using for several months and seems to give the most satisfactory results, with no failures to date, is the following. The vagina is wiped dry of all discharge and is painted with a 1 per cent aqueous solution of gentian violet. After this has dried for a few moments, an amebicide powder mixture, suggested by Gellhorn, is blown into the vagina by means of a powder blower. The powder mixture consists of acetarsone and equal parts of kaolin and sodium

bicarbonate. The average dose is 1 teaspoonful of the mixture, containing $7\frac{1}{2}$ grains (0.5 Gm.) of acetarsone, and this dosage is usually doubled when treatment is given during the menstrual period or a pregnancy. The powder blower is so designed that it causes a ballooning out of the vagina, and thus the powder is deposited in all the crevices and folds of the vaginal mucosa. The treatments are given every second day and the number has varied from four or five to a dozen or more. Douches, baths and coitus are not permitted. Several stubborn cases treated by other agents have responded readily to this more recently tried method. For patients who for some reason cannot take the treatment, lactic acid is usually prescribed for douching, but vinegar is just as effective, and the author has one poor patient who completely eliminated the infection by the use of vinegar douches.

Etiology of Degenerative Vascular Disease—Sprague states that it is impossible to differentiate clearly intimal and medial processes, or to subdivide hyaline, fatty, fibrous and calcific changes from one another. Vascular disease has been attributed to the following factors: material voluntarily ingested, material involuntarily ingested, inhaled or acquired parenterally, toxic products endogenously elaborated in the body, such as occur in metabolic disorders, general strain on the vascular tree from hypertension or excessive bodily activity or local strain on special vessels from their anatomic situation or structural peculiarities, as in the pulmonary or coronary circulation, acceleration or exaggeration of the changes normally occurring in old age, chiefly dehydration, loss of muscle cells, elastic tissue and power of regeneration, deposit of lipoids and calcium salts in the cells and changes in the colloid state of the tissues, endocrine influences through hypo-activity, hyperactivity or dysfunction, influence of psychic factors and speed of modern life on vascular irritability, and climatic factors. The cause of degenerative vascular disease is unknown, but the boundaries of the problem are being progressively narrowed by the study of experimental arteriosclerosis of chemical analysis of vessels, of the properties of colloidal gels and of human biology. No theory of etiology is wholly satisfactory to explain premature death from disease of the blood vessels. Acceleration of the normal changes of age seems to be inherent in certain familial or racial groups and can be abolished only by a wide, and probably impossible, application of human genetics. Enough evidence exists to make it probable that there are controllable factors of environment, which in some cases can be altered in such ways as to delay the process of aging or change its manifestations.

Allergy as Cause of Agranulocytosis and Purpura—Hunter cites the arguments that the agranulocytic and purpuric syndrome is a manifestation of allergy, and those which have been advanced to show that it is a result of primary injury to the liver. Agranulocytosis occurs in susceptible individuals following the ingestion of aminopyrine, but in less than 10 per cent of the reported cases this drug has been proved, by further ingestion tests, to be the causative factor. Typical clinical

agranulocytosis may result from injections of arsphenamine, gold salts or foreign protein or from the ingestion of dinitrophenol. Agranulocytic purpura has been attributed to arsphenamine and to quinine, thrombopenic purpura and aplastic anemia, to arsphenamine and to gold salts, but many of these cases have been incorrectly referred to as pure agranulocytosis. In view of the difficulty of drawing definite dividing lines between various blood dyscrasias, and since arsphenamine can produce any of them, they may be manifestations of a physiologic mechanism similar to allergy, which, in turn, may be dependent on injury to the liver. There is not enough evidence in the literature or in the author's twenty-seven cases to justify the statement that injury to the blood-forming organs from the use of drugs or foreign protein occurs more frequently in allergic patients than in normal individuals, or more often in patients presenting evidence of past liver injury than in those without it. The author concludes that agranulocytosis is a syndrome rather than a clear cut clinical entity of established etiology and may be occasioned by a number of substances, such as aminopyrine, arsphenamine, gold salt, dinitrophenol and foreign protein. It, together with some allied blood disorders, probably belongs in the category of allergic phenomena and may even be conditioned by functional damage to the liver.

Mineral Constituents in Fresh and Canned Milk.—Hermano and Claravall analyzed forty-five samples of milk for their calcium, iron, phosphorus, fat and ash contents. The results for evaporated whole milk, powdered whole milk and sweetened condensed milk agree, in general, with the data given by the associates of Rogers for these products. Fresh cow's milk gave a higher percentage of ash and calcium than the natural sterilized milk. Milk from carabaos had the lowest ash content (0.64 per cent), but the ash had the highest amount of calcium (27.99 per cent). Carabao milk also had more fat and protein than the other natural fresh milks. The Toggenberg breed of goats gave milk with a higher calcium content than any other breed of goats. Whole powdered milks gave the highest percentage of fat.

Treatment of Arthritis with Colloidal Sulfur.—Woldenberg employed colloidal sulfur in the treatment of 231 cases of atrophic and five of hypertrophic arthritis and in fourteen cases of muscular rheumatism. Every case showed excellent clinical improvement, and the results were obtained in a much shorter period of hospitalization than previously known. All these patients except six were discharged from hospitalization with a complete arrest of the active symptoms of the disease. Great care was exercised in each case in establishing the diagnosis of arthritis. The familiar symptoms were confirmed by a thorough examination of the nature of the inflammation and the tenderness complained of in the affected joints. In addition, the diagnosis was confirmed by roentgen studies of each joint in which any change had occurred, and in every case of arthritis in this series abnormal shadows showed extraordinary joint alterations. Coexisting diseases were found in many of these patients. All foci of infection when present were cleared up as far as possible. The routine eradication of teeth and tonsils was not done unless it was apparent that they were factors in the causation of the arthritic process. Protective and corrective treatment was carried out whenever indicated. Chronic constipation, an extremely common condition among these patients, was corrected. While anemia, as shown by low hemoglobin and a slight reduction of the red cells, was mostly mild, the best nutritional state possible was secured for each patient. Generally they were placed on a high vitamin, low carbohydrate, low caloric diet, with 50 or 60 Gm of protein and the necessary amount of fats according to the patient's caloric requirements. Exercises gradually increasing in vigor were given daily throughout the treatment. The colloidal sulfur used was supplied in 2 cc. ampules said to contain 10 mg of colloidal sulfur disbursed in a protein-free aqueous medium for intravenous medication and in 2 cc. ampules containing 20 mg of colloidal sulfur suspended in an acid-free olive oil for intramuscular medication. In the severe type and long standing cases, showing a low cystine content of fingernail clippings and a high sedimentation rate, 30 mg of sulfur was

given every day until a course of ten injections had been completed. The more satisfactory results were obtained from the intravenous medication. The majority of the patients were free from pain after the fifth or sixth injection and the spasticity of muscles began to disappear. The effusion in the joints gradually became less, and after about three or four weeks of treatment it was practically gone. Great care was taken when giving colloidal sulfur intravenously to inject it slowly, to prevent any leakage into the soft tissue, as the latter causes excruciating pain and sometimes sloughing of the soft part at the vicinity of the point of injection. In the most recent cases, the cystine and sedimentation tests, supported by the clinical observations, have enabled the author to treat very acute cases with doses as high as 30 mg of colloidal sulfur intravenously daily for a full course, and as a result completely ridding the patients of the intense pain they were suffering within thirty-six hours of the first injection. It is his opinion that the larger doses administered at more frequent intervals are the most important factor in the beneficial results obtained with sulfur therapy in arthritis.

Chronic Atrophic Dermatitis of Vulva—Adair and Davis state that the present terminology—kraurosis, leukoplakic, vulvitis, leukokraurosis—is unsatisfactory, as it describes only certain phases of this condition. It leads to failure in making a diagnosis of the early stages of the disease prior to the development of the shrinkage of kraurosis or the white areas of leukoplakia. Chronic atrophic dermatitis of the vulva is a simple and descriptive term for the entire process in its various manifestations. In a period of five years the authors have encountered twenty-three patients with typical chronic atrophic dermatitis of the vulva, an incidence of 0.24 per cent. Vulvectomy was done in nine cases with uniformly good results. Various types of treatment were given, including irradiation in the majority of the cases with only temporary relief. The disease is progressive and does not tend to regress spontaneously, although there may be periods of quiescence. Surgical removal of the involved tissue is the only safe, logical and effective treatment in alleviating the symptoms and arresting the progress of the disease. The condition is to be regarded as a precancerous lesion with an incidence of carcinoma in more than 50 per cent of the cases. Vulvectomy is further justified as a prophylactic measure against carcinoma of the vulva.

Experimental Peptic Ulcer—Blanck shows that gastrointestinal ulceration can be prevented in dogs with biliary exclusion by the adequate feeding of fresh bile obtained from dogs. Gastric changes were observed in the pyloric region in three dogs. Another characteristic of the associated gastritis as observed in man and in the animals was the patchy distribution of the pathologic areas. The destruction of the epithelium of

the surface and necks of the pyloric glands constituted the earliest type of alteration in these glandular structures. Cystic dilatation of some of the glandular structures was noted in the necks of pyloric glands of one dog and in Brunner's glands of the duodenum in another dog. In the fundus mucosa of one dog an increase in the amount of interstitial tissue resulting in a forcible separation of the closely packed gland tubules was observed. There was also a destruction or atrophy of the glandular cells manifested first in the necks of the glands and then in the fundus portions. In the regions in which the process had progressed sufficiently to destroy entire tubules, there often could be seen one or more nests of from one to six parietal cells lying as vestiges in the path of the destructive process. These cells presented intact cell outlines and perfectly normal appearing nuclei. In the changes observed in the duodenums of the animals there was chiefly a loss of epithelium covering the villi. In some areas there was in addition a beginning erosion of the tips of the intestinal villi. The sections stained in muchematein solution, as long as any portion of the cell cytoplasm remained, continued to give the characteristic staining reaction, confirming the work of Whitlow that mucus laden and mucus covered cells are more resistant to acid pepsin digestion than other cells. Although these cells possess a natural power of protection they finally succumb to the influences of the destructive process. Of the changes occurring on both sides of the pyloric ring, those on the stomach side are progressive and constitute chiefly a loss or atrophy of the gland structures, and on the intestinal side of the pyloric ring the changes are manifested by a continual loss of tissue. The author believes that this fact explains why there is a preponderance of the duodenal lesion over the gastric lesion in peptic ulcer disease.

Surgical Treatment of Joint Tuberculosis—Cleveland believes that tuberculosis of the joint as a distinct entity does not exist. Manifestations of tuberculosis in the joints must be considered as tuberculosis with a primary focus in the lungs, lymph glands or tonsils, in which the joint has been secondarily invaded. The condition of the lungs, upper respiratory tract, gastro-intestinal tract and genito-urinary tract is of paramount importance in these cases, which must be studied as a whole in relation to the tuberculous infection. Until each series of cases reported with joint tuberculosis is so studied, exact knowledge of the problem of treatment or prognosis cannot be arrived at. In the author's 210 patients the average age of onset was 22 years. The mortality was 28.5 per cent and will undoubtedly be higher as time goes on and the number of deaths is augmented from the list of cases that he considers uncertain. In the first decade of life the mortality in this group was only 14.8 per cent, but in the third decade the mortality mounted to 46 per cent. Patients with positive sputum and caseous pneumonic lesions, and those with pulmonary disease and negative sputum, but with metastatic spread to other organs, have shown a mortality of 52 per cent. On the other hand, patients with inactive pulmonary disease and no metastatic spread to other organs and those with no evidence of pulmonary disease have shown a mortality of only 9 per cent. A factor that adversely influences the end result is prolonged suppuration from sinuses with resulting amyloid disease. The only joints that tend to fuse spontaneously are those of the spine. This occurs in only 22 per cent of the cases and then only after many years and the development of tremendous deformity. A study of the end results of the 224 joints treated shows that the joints of the upper extremities and the tarsal and ankle joints had the highest percentage of excellent results, 70 per cent or better. The knee joint cases showed 61 and the spine cases 54 per cent of excellent results. The percentage of excellent results fell to 44 in the hip joint cases and to 37.5 in the sacro-iliac joint cases. As the excellent results declined, the mortality rose. The sacro-iliac joint with a mortality of 43.5 per cent is, in the author's experience, the gravest form of joint tuberculosis, while the knee joint and joints of the upper extremities offer the best prognosis. The operative treatment aimed at eliminating the surgical focus by putting the joint or joints involved at complete rest, by operative fusion. If a joint of an extremity was overwhelmingly involved and any attempt to save it endangered the patient's life, amputation was resorted to.

Experimental Removal of Cerebral Hemispheres—

Lebedinskaja and Rosenthal removed the cerebral hemispheres of a young male dog by two successive operations carried out without great loss of blood and without damaging the subcortical matter. They found that a small portion of cerebral cortex is sufficient for the establishing of simple conditioned reflexes. Motor disturbances pass away almost completely in the course of time. The sleep is deeper and sounder than that of normal dogs, owing to the absence of the cerebral cortex, which is a more sensitive mechanism to internal and external stimuli than the subcortical matter. The internal functions of the organism (metabolism, temperature regulation) depending on the subcortex remain satisfactory. The dog lost sight and smell. Taste remains more or less normal. Cutaneous sensibility to mechanical and thermal stimuli is lowered. The unconditioned orientation reflex to sounds and noises is preserved. Explorations (investigatory movements of the head) are preserved and can be easily mistaken for olfactory reactions, which in reality are absent. The mating (sex) instinct may be preserved but incompletely. The dog was unable to find his food without assistance. Fits or convulsions of the tonic type were not observed. The dog lived without cerebral hemispheres for one year and two days after a third fit of convulsions. At necropsy, the dura mater was found adhering closely everywhere to the remnants of the brain tissue. It was very much thicker than normal, especially at the posterior part near the tentorium cerebelli, as well as along the middle line above the fissura cerebri magna, where the thickness of the scar exceeded 1 cm. On its internal surface the dura mater adhered closely to the surface exposed by the removal of the cerebral hemispheres. Scars were found in front, in the region of the olfactory lobes, which were destroyed by the operations. All the nerves of the base of the brain were intact and were not adherent to scar tissue. Transversal sections made from the medulla oblongata to the front end of the tractus olfactorius at a distance of from 2 to 3 mm. from one another have shown that: 1 The lower posterior horn of the left lateral ventricle was absent to the middle of the thalamus. 2 In that part the dura mater modified by the scar adhered directly to the subcortical matter. 3 Owing to the secondary scar formations the cornu ammonis on the left was hardly discernible. 4 In front of their middle parts both lateral ventricles were intact and descended together with the fornix toward the front part of the base of the brain. 5 The right gyrus pyriformis was intact the left was damaged. 6 Near the right gyrus pyriformis a well preserved portion of the auditory area of the cortex-gyrus compositus posterior was found.

Agranulocytosis with Purpura Haemorrhagica Following Gold Therapy. Note on Prevention of Complications P Ellman and J S Lawrence. —p 622

Agranulocytosis Following Gold Therapy—Ellman and Lawrence present a fatal case of hemorrhagic purpura with agranulocytosis following gold therapy. They divide the complications of gold therapy into effects on the skin, the mucous

membrane the liver and kidneys and the hematopoietic system. They emphasize that, apart from a few cases of degenerative hepatitis, accidents due to gold therapy have proved fatal only when the hematopoietic system has been involved. Émile Weil and Bousser consider the causation of toxic manifestations due to a sensitivity to gold. The most effective treatment of agranulocytosis is blood transfusions repeated as often as is found necessary. Subcutaneous injections of blood have also been used and epinephrine and liver by mouth. Dextrose intravenously, sodium thiosulfate or magnesium and sodium nucleinate are also recommended. Before starting gold therapy the patient should always be questioned with regard to a personal or family history of purpura or bleeding. Gold salts should not be given to patients with such a history. They should likewise not be given following substances that affect the bone marrow such as thorium. Blood counts should be carried out frequently during the treatment in order to detect an incipient agranulocytosis, aplastic anemia or thrombocytopenia. The necessity for this in the gold treatment of rheumatoid arthritis cannot be overemphasized. If the eosinophil count rises above 5 per cent the injections should be discontinued temporarily. As erythema is a sign of intolerance to gold, the authors discontinue the injections when it occurs. On recommencing half the previous dose is employed.

Electrocardiogram of the Normal New-Born—Hori and his associates examined the electrocardiograms of 126 mature new born infants and thirty-four premature infants. Irrespective of the maturity or prematurity of the new-born, the preponderance of the right ventricle was proved in all the cases and every wave was lower than that in the suckling, infant or adult. The abnormal electrocardiogram was observed more frequently in the premature new-born infants, especially in those electrocardiographed on the first to the third day after birth than in the mature infant.

Carotid Sinus in Pulmonary Edema—The carotid sinus is situated in the enlargement of the internal carotid after the bifurcation of the common carotid and consists of a plexus rich in nerve fibers which connect with the bulbar nuclei and the vagus centers. According to Salmon, the functional relations of this sinus with the bulbar respiratory nucleus is also interesting. It has been shown that mechanical excitation of the sinus modifies constantly the amplitude and rhythm of respiratory movements. Thermal stimulation of this organ produces an acceleration of the same movements. Depression of the sinus results in apnea, which ceases after the removal of the depressive agent. These and other factors have value in explaining the pathogenesis of acute pulmonary edema. The connection between the sinus and the bulbar nuclei does much to explain the fact that these crises of pulmonary edema having all the characters of bulbar vagotonic phenomena are usually produced by agents affecting the sympathetic, by injections of epinephrine and by emotions, hypertensive crises, strongly painful sensations, experimental excitation of sympathetic ganglions, brain lesions resulting in irritation of the nuclei of the third and fourth ventricle and similar stimuli.

Treatment of Fracture of External Malleolus—According to Winterstein fractures of the external malleolus are especially frequent in ski runners. He shows how a fracture can be differentiated from a distortion and thinks that roentgenoscopy is usually unnecessary. In discussing the treatment, he says that some recommend small bandages and early mobilization and that others advise a plaster-of-paris cast, which remains in position for from two to six weeks and is then followed by mobilization. He concedes that the plaster-of-paris cast gives satisfactory results in most fractures but shows that prolonged functional impairment and weakened muscles are frequently the result of this treatment. With other surgeons he is of the opinion that the plaster-of-paris cast goes beyond the aim. Since 1919 his clinic has followed Clairmont's suggestion in that it employs the so called Gradl bandage for the fractures of the external malleolus in which there is no dislocation. As soon as a definite diagnosis has been reached, a strong linen bandage, 5 cm. in width and 5 meters in length, is put on in the form of an ascending spica of the foot, beginning at the toes and going up to three fingerbreadths above the malleolus. The linen bandage is covered with a gauze bandage. The foot is placed on a small hard cushion with lateral sand bags and an ice bag. At intervals of several hours the bandage may be moistened with cold water or with aluminum acetate. As the bandage dries, the pressure becomes more intense. According to requirement, the bandage may be removed for a time every day. Massage, which should be painless and should not touch the malleolus itself, is not begun until after at least three days. Active exercises may be begun a few days later, resistance exercises being especially helpful. Daily warm baths, the temperature of which is gradually increased, are beneficial. After about a week it is no longer necessary to keep the bandage constantly moistened. Rest in bed is necessary for a short time but when the patient sits up it is advisable to elevate the leg. Standing and walking should at first

be done without putting a strain on the leg with the fracture. In young persons this is possible after about a week, in middle aged persons after from two to five weeks.

Pathogenesis of Thromboses—Wantoch points out that since Virchow's time most authors have accepted the theory that three factors are involved in the development of thrombosis, namely, retardation of the speed of the blood current, impairment of the vascular epithelium and changes in the composition of the blood. The author shows that opinions differ about the relative importance of these three factors, some stressing the one and some the other as the most important one. However, recently the opinion has gained ground that changes in the composition of the blood are the most important factor in the pathogenesis of thrombosis. In discussing this factor, the author evaluates the resorption of the decomposition products of protein, the condition that is produced by protein and serum therapy and the importance of injections and of diuretics. He describes the observations made in the course of postmortem examinations. At his clinic, 367 cases of fresh thrombosis and embolism were found in the course of 4,739 necropsies. After mentioning the various pathologic conditions found in these 367 cases, he asserts that there were only twenty cases in which there was no disorder that is accompanied by changes in the blood, pointing out that the composition of the blood is altered not only in the conditions in which a predisposition to thrombosis exists but also in case of transudates and of stasis. He thinks that it may be concluded with some reservations that the accumulation of fluids in the cavities and tissues of the body is connected with a tendency to thrombosis. It was found also that, the more conditions concur which have a tendency to thrombosis, the more likely is the development of a thrombosis. The author was unable to corroborate that obesity or endocrine factors play a determining part in the pathogenesis of thrombosis, and, in reviewing the opinions on the connection between thrombosis and meteorological conditions, he says that as yet nothing definite is known about this relationship.

- *Skin Reaction to Histamine and to Epinephrine in Scarlet Fever A. Colarizi.—p 661
- Acute Hypo-Adrenalism in the New Born A. Martinetti.—p 706

Skin Reaction to Histamine and Epinephrine in Scarlet Fever—Colarizi observed a marked refractoriness of the skin capillaries to histamine and to epinephrine in forty-two cases of scarlet fever. This lack of reactivity became less pronounced in a few days. Hypo-excitability and sometimes total loss of excitability were observed in the advanced stage of the disease in two patients presenting postscarlatinal nephritis. This study, comprising 270 cutaneous tests threw light on the nature of the lesions of the cutaneous vessels in scarlet fever and contributed to the understanding of the Schultz-Charlton phenomenon of rash extinction. The author investigated the various phases of the reaction as manifested by the behavior of the capillaries, veins and arteries toward the pharmacodynamic substances, comparing the skin of healthy persons, of scarlatinal exanthems and of the areas of fading rash. He found that the capillaries exhibit diminished permeability (urticaria reaction to histamine) and diminished contractility (ischemic reaction to epinephrine) as much in the exanthematous area as in the area of fading rash. He states that a lack of arterial contractility (erythematic reaction) is more evident in the zone of fading rash than in the exanthematous portion. The changes in the cutaneous blood vessels to which the rash extinction is due are first observed in the arterial and venous circulation and after that in the capillary loops. The changes are due to the persistence of the lesions in the exanthematic skin. This is explained by the fact that the capillary loops are more affected by the toxic action of scarlet fever and that a certain time elapses before the walls of the capillaries recover from their lesions. The changes in the veins and in the arteries of the area of fading rash, resulting in the cessation of hyperemia, may be explained as an increase of the tonus. Although this hypertonia does not compare with the ischemia induced by epinephrine it inhibits and limits the response to the vasodilatory stimuli. The extinction phenomenon

enon always occurs as a regular round spot. The author concludes that the Schultz-Charlton phenomenon is one of the best tests of regulation of the tonus of the small cutaneous vessels.

- *Allergy to Extract of Cancer Tissue. Importance of Desensitization in Prevention of Cancer. S. Citelli.—p. 2031
Treatment of Pulsating Exophthalmos. A. Chiasserini and A. Tommasini Mattiucci.—p. 2034

Allergy to Extract of Cancer Tissue—Citelli states that the subcutaneous injection of 1 cc of the whole extract of cancer tissue given persons while fasting produces a hemoclastic reaction in about 85 per cent of the patients suffering from cancer and in about 15 per cent of noncancerous persons (generally over 40 years old and belonging to cancerous families). The allergic condition in the last group may be spontaneous or produced by injecting intravenously, also while fasting, 8 or 10 cc of blood serum, previously centrifuged, of either noncancerous persons with a positive test or of cancerous patients. It disappears after three subcutaneous injections given at weekly intervals. The desensitization persisted after three years in the only two patients out of a group of eleven in whom the results were verified. The test is specific for cancer. The author advises desensitization of noncancerous persons who have a positive reaction by administering three subcutaneous injections of whole extract of cancer tissue given in doses of 8 or 10 cc of the extract per injection at weekly intervals, as a new preventive treatment of cancer.

Surgical Treatment of Detachment of Retina. Safar's Technic. R. F. Pereira.—p. 1859
Anatomoclinical Forms of Pulmonary Syphilis in Adults. D. Vivoli.—p. 1875

Absence of Pericardial Murmur in Myocardial Infarct—Bosco states that there are certain cases of myocardial infarct in which the pericardial murmur cannot be heard on auscultation of the heart. The audibility of the murmur depends on the topographic situation of the occluded coronary arterial branch, the intensity of myocardial necrosis, the site of development of the fibrous pericarditis that follows myocardial necrosis, and the development of the disease. The actual murmur is due to the anatomopathologic alteration of the pericardium and is audible only during the first stage of the disease, which is rather brief, and then only when there is intense necrosis of the anterior wall of the myocardium and the seat of fibrous pericarditis that follows is accessible to auscultation on the anterior wall of the thorax. These conditions are produced only by occlusion of the anterior descending branch of the left coronary artery. When the occlusion takes place at the posterior descending branch of the right coronary artery or at any of the two circumflex branches of the right and left coronary arteries the murmur is inaudible at auscultation.

Method of Prolapse Operations. F. Orthner.—p. 1682

Hormone Preparations and Coagulability of Blood—Bablik cites investigators who observed that estrogenic substance promotes the coagulation of the blood and describes experiments that he made with testis hormone. He found that the testis hormone considerably retards the coagulation. Since the testis hormone retards the coagulation and estrogenic substance accelerates it, it may be assumed that in case of an oversupply of the one or the other, the coagulability is influenced

in a corresponding manner. The author thinks that this conclusion is justified also by observations on thrombosis and embolism on the one hand and on hemophilia on the other.

Carotene-Vitamin A Metabolism and Thyroid—Wendt cites animal experiments in which it was demonstrated that the thyroid influences the vitamin A metabolism and describes his own studies on human subjects. He found that in human hyperthyroidism, in exophthalmic goiter, the examination of the serum disclosed a considerable reduction of the carotene and particularly of the vitamin A values. He says that vitamin A may be entirely absent from the serum in severe cases of hyperthyroidism. After successful treatment with iodine or by surgery, the values increase. If patients with hyperthyroidism are given large quantities of vitamin A, their weight increases and their metabolic rate recedes to almost normal values. The author investigated also the carotene and vitamin A metabolisms in patients with hypofunction of the thyroid, in myxedema and cretinism. In myxedema patients he found that the transformation of carotene into vitamin A is disturbed. In patients with cretinism the vitamin A values of the serum are considerably reduced, and it appears that this reduction is essentially a result of the transformation disturbance of carotene into vitamin A, but the lack of capacity to store vitamin A also seems to play a part in cretinism.

Blood Chemistry in Parathyroparvetic Tetany—Siwe aimed at determining what action the hypofunction of the parathyroids exerts on the calcium and phosphorus contents of the blood and on the ultrafiltrable fractions of these substances. He also wished to see whether an increased amount of parathyroid extract in the organism would produce chemical changes that would be the exact opposite of those found in acute or chronic insufficiency of the parathyroids. He summarizes his observations as follows: 1 In acute insufficiency of the parathyroids (parathyroidectomized dogs) the total calcium content of the blood may decrease before the inorganic phosphorus has commenced to increase. 2 This indicates that the insufficiency exerts its effect first on the total calcium and later on the phosphorus content of the blood. 3 When the phosphorus increases the total calcium does not necessarily have to show the lowest values, although the tetany may be fully developed. 4 The ultrafiltrable calcium fraction may become reduced, but it does not do so always and it never goes below the values corresponding to the amount ionized at the pH of the blood. 5 In case of chronic insufficiency of the parathyroids in human subjects and after it, the ultrafiltrable calcium may be normal, even if the total calcium content is reduced. The organic phosphorus content is, independent of the calcium level, either normal or slightly increased and its ultrafiltrable portion is present in normal values. 6 Administration of parathyroid extract produces in rabbits an increase in the total calcium content of the blood and a considerable increase in its ultrafiltrable portion in the arterial blood. 7 The intake of parathyroid extract results also in a considerable increase of the inorganic phosphorus in the blood and of its ultrafiltrable portion in the arterial blood. 8. Here and in other experiments it is shown that the total calcium content as well as the organic phosphorus may differ in the arterial and in the venous blood. At any rate, the difference does not become greater in the case of parathyroid insufficiency and there are indications that it has a tendency to decrease following the administration of parathyroid extract. 9 For this reason the behavior of the ultrafiltrable fractions is the more surprising. Whereas under normal conditions and in parathyroid insufficiency the ultrafiltrable portion of phosphorus is not constantly different in the arterial and venous blood, since under normal conditions the ultrafiltrable calcium is slightly

higher in the arterial than in the venous blood, and although the ultrafiltrable calcium is slightly increased in parathyroid insufficiency, the differences are great in case of administration of parathyroid extract. In the latter case the ultrafiltrable calcium in the arterial blood may be twice as high as in the venous blood. The corresponding phosphorus fraction varies by 50 per cent or more in the same direction. This happens in spite of the fact that in case of the administration of parathyroid extract the variations in the total calcium and in the inorganic phosphorus are unusually small in both types of blood. The addition of parathyroid extract to the serum in vitro corroborates the results of the animal experiments.

Hepatic Function and Takata Reaction in Children's Disorders—Recht calls attention to the fact that Jegler's adaptations for the serum of Takata's original cerebrospinal fluid reaction indicate changes in the colloid chemistry of the serum. In the development of these changes the liver plays an important part, and it is generally accepted that a positive Takata reaction indicates severe hepatic lesions. To be sure, in nurslings and small children the disorders for the detection of which the Takata reaction is used in adults are rare. If the finer changes in the hepatic function that occur in nurslings and children are to be detected with the Takata reaction, mere positivity or negativity of the reaction is not sufficient. The author gained the impression that not the quantity of the precipitate is important for the diagnosis but rather the appearance of the precipitate in lower or higher dilutions. Studies on sixty nurslings and twenty-six children revealed that under normal conditions the precipitate begins at a dilution of 1:8. If flocculation appears at higher or lower concentrations, it may be assumed that a disorder exists. The author maintains that in disturbances of nurslings and children the colloid chemical changes can in many cases be determined by means of the Takata reaction.

Characteristics of Heinz Bodies—In order to determine whether the inclusion of Heinz bodies within the erythrocytes is a degenerative or a regenerative process, as well as to determine the physical and chemical characteristics of these bodies, Vinogradskaya and Kirichenko studied the blood of a rabbit in which they produced aniline poisoning by subcutaneous injection of a solution of aniline in oil. They found that the number of Heinz bodies increased in the course of the acute experiment and reached its maximum within from twenty-four to forty eight hours. The diminution in the number of Heinz bodies was accompanied by a rise in the number of the reticulocytes. The Heinz bodies are not soluble in substances that dissolve lipoids and probably do not represent a purely lipid structure. The resistance of an erythrocyte containing Heinz bodies is lowered but that of the bodies themselves is increased. Oxygen absorption capacity by erythrocytes containing Heinz bodies is considerably less than that of reticulocytes, which fact may serve as an index to the age of the erythrocytes. The presence of Heinz bodies within mature erythrocytes speaks for their degenerative character.

Hydroxyestrin Benzoate in Treatment of Rheumatoid Arthritis—Kuipers treated three women suffering from chronic rheumatoid arthritis with intramuscular injections of

hydroxyestrin benzoate (Progynon B). The weekly dosage for one patient, aged 53, was from 25,000 to 50,000 mouse units for a period of twelve months. Two patients, aged 54 and 23 received 50,000 mouse units weekly for a period of six months. These two patients, who had suffered from the disease for twenty and for sixteen years, responded well to treatment. The patients showed better posture, diminution of the periarticular swelling and return of normal skin temperature. The younger patient, in addition, showed a decrease in the osteoporosis. In all patients the pain increased occasionally during treatment and was accompanied by more articular crepitation. The women suffered from irregular bloody discharges and other minor menstrual disturbances. The third patient, presenting clinical symptoms of secondary chronic rheumatoid arthritis of the feet, gave a roentgenogram of osteo arthritis. During treatment she showed functional improvement, but no changes occurred in the roentgenogram.

Treatment of Tuberculosis of Larynx in State Sanatorium S F Nielsen and J N Lorenzen—p 1018
Treatment of Opium Eaters with Strychnine and Sodium Thiosulfate P Wedel—p 1022

Epidemic and Endemic Poliomyelitis—Nissen states that 192 patients were treated in the Copenhagen poliomyelitis endemic. Morbidity was relatively high among older school children and adults, and was higher among men than among women. Dementia paralytica occurred most frequently in girls. A study of ninety-seven preparalytic cases showed that the symptoms of drowsiness, unrest, fibrillation, tremor, perspiration, muscular tenderness and a dysphasic picture appeared oftener in the patients in whom dementia paralytica set in after one or more days. In contrast to epidemic poliomyelitis, the absolute cell count is apparently not of especial prognostic value in endemic poliomyelitis. The dementia paralytica generally occurred on the second or third day, the frequency was highest in infants and children at home, decreasing toward school age and increasing again later. The mortality was lowest in infants rising with the age. The degree of dementia paralytica and the prognosis were considerably more favorable in children at home and school children than in the older age group. As in epidemic poliomyelitis, the degree of the endemic disease depended on the season of the year.

Blood Picture in Poliomyelitis—Plum says that in poliomyelitis the white blood picture usually shows a slight neutrophil leukocytosis, more marked in grave than in mild cases, with slight shifting to the left. The leukocytosis subsides slowly. In respiratory paralysis a relatively great increase in the number of granulated cells appears immediately before the paralysis, with slight shifting to the left and moderate increase in the absolute number of leukocytes. Similar changes were noted in three cases of poliomyelitis with bulbar paralysis. The blood picture in nonparalytic poliomyelitis does not differ from that in cases with slight paralysis. The author considers the white blood picture a valuable aid in doubtful cases of poliomyelitis, especially in the differential diagnosis between pneumonia complicated with serous meningitis (meningism) and nonparalytic poliomyelitis.

THE CAUSES OF BLINDNESS IN CHILDREN

THEIR RELATION TO PREVENTIVE
OPHTHALMOLOGY

CONRAD BERENS, M D
C. EDITH KERBY, B A
AND
EVELYN C. McKAY, B.A.
NEW YORK

A study of 2,702 children in schools for the blind in the school year 1933-1934 disclosed certain facts concerning the causes of blindness and the possibilities for preventive work that made it seem desirable to direct the attention of ophthalmologists to the eye conditions incident in the younger age groups. This paper is presented in the hope that the dissemination of the information secured may make it possible to obtain more reliable data which will stimulate medical research and programs for the prevention of blindness.

Reliable information on causes of blindness has been lacking. Even when detailed studies have been made they have been limited to a comparatively small number of patients or to a restricted geographic area, so that they could not be considered representative, and because the methods and classifications used lacked uniformity, the results of these studies could neither be compared nor totaled scientifically.

Recognizing this difficulty, the Committee on Statistics of the Blind¹ set up a standard classification of causes of blindness² which could be applied to any group and which would make possible uniform statistics for the entire country. This classification was prepared with the advice and cooperation of a number of ophthalmologists, and in 1934 the Section on Ophthalmology of the American Medical Association desig-

Read before the Section on Ophthalmology at the Eighty Sixth Annual Session of the American Medical Association Atlantic City N J June 13 1935

The members of the Committee on Statistics of the Blind acknowledge with grateful appreciation the valuable assistance they have received from ophthalmologists throughout the country both in constructive criticism during the development of these classifications and in cooperation during the studies made in the schools for the blind.

1 The Committee on Statistics of the Blind sponsored jointly by the American Foundation for the Blind and the National Society for the Prevention of Blindness was appointed in 1930 to act as a coordinating body whose chief functions are to develop standard methods for recording and summarizing information adaptable to statistical treatment and to act as a central agency for the collection, analysis and distribution of these data. The members of the committee are Conrad Berens M D ophthalmic surgeon New York Eye and Ear Infirmary Lewis H Carris managing director National Society for the Prevention of Blindness Ralph C. Hurlin Ph D chairman director Department of Statistics, Russell Sage Foundation Robert B Irwin executive director, American Foundation for the Blind C Edith Kerby statistician, National Society for the Prevention of Blindness Evelyn C. McKay research agent, American Foundation for the Blind Bennet Mead statistician United States Department of Justice B Franklin Royer M D Stetson K. Ryan executive secretary Connecticut Board of Education of the Blind.

2 The standard blanks and classifications mentioned in this paper may be obtained without charge from the secretary of the Committee on Statistics of the Blind 15 West Sixteenth Street, New York.

nated a committee (under the chairmanship of Dr T B Holloway) to serve in an advisory capacity to the Committee on Statistics of the Blind.

METHOD OF STUDY

In the academic year 1933-1934, at the invitation of a group of schools for the blind,³ the Committee on Statistics of the Blind made a study of causes of blindness among pupils in these schools. Eighteen residential schools and the public school braille classes of two cities were included, a total of 2,702 children. Since this number represents nearly half the children registered in schools for the blind, and since the institutions studied were widely scattered geographically, this group may be considered representative of the country as a whole.

The examining ophthalmologist was asked to record his observations on a special report form (fig 1). This form does not require a detailed record of a complete ophthalmologic examination but only the minimum of medical data, in summary form, that is considered essential for the intelligent solution of problems relating to the child's education, vocational guidance and medical care, as well as for statistical purposes. Especial attention is called to the heading "diagnosis," with its three subdivisions (1) eye condition primarily responsible for blindness, (2) secondary conditions, if any, and (3) etiologic factor responsible for the primary eye condition.

THE IMPORTANCE OF ETIOLOGY

Etiology is stressed as a separate question because experience has shown that the ophthalmologist tends to record his diagnosis in terms of the nature and location

cated by the mental condition of many of these children Holloway⁴ reports that 437 per cent of the pupils at the Overbrook School for the Blind fall into the group of the dull, backward or feeble-minded

CLASSIFICATION BY CAUSE⁵

Data on the causes of blindness are presented according to an etiologic and a topographic classification. The plan is similar to that of the Standard Classified Nomenclature of Disease,⁶ but the lists of the Committee on Statistics of the Blind include only conditions that may lead to blindness.

Etiologic Classification—In this classification (table 3) the causes are grouped under six main headings: (1) infectious diseases, (2) traumatic and chemical injuries, (3) toxic poisoning, (4) neoplasms, (5) non-infectious systemic diseases, and (6) congenital and hereditary. Under each heading the individual items represent the causes that occur most frequently, but there are two general items to cover other specified cases of the same nature and those cases belonging in the group but not specified. The inclusion of the latter type of item under each heading makes it possible to reduce the miscellaneous "unknown" group ("etiology not specified") to a minimum.

The congenital and hereditary group accounts for more than half the cases of blindness among children (51.1 per cent). This group is subdivided into two parts. In one part are the hereditary and familial cases (11.6 per cent) in which have been included all those specified as hereditary by the examiner and also those specified as "congenital" but suspected of being hereditary because of the presence in the same school of sisters or brothers with the same eye condition. It seems quite probable that, if family histories of all cases in the congenital group could have been studied,

TABLE 1—Age Distribution

| Present Age (as of 6/1/34) | Total Pupils | Per Cent of Total |
|----------------------------|--------------|-------------------|
| All ages | 2,702 | 100.0 |
| Under 6 years | 3 | 0.1 |
| 6 to 9 years | 856 | 31.7 |
| 10 to 14 years | 954 | 35.3 |
| 15 to 19 years | 934 | 34.6 |
| 20 years and over | 594 | 22.0 |
| Age not reported | 61 | 2.2 |

TABLE 2—Distribution by Amount of Vision Remaining

| | Number | Per Cent |
|--|--------|----------|
| Total 40 schools and classes reporting | 2,702 | 100.0 |
| Group 1 (total blindness or light perception only, less than 2/2000) | 1,003 | 37.1 |
| Group 2 (2/200 but not 5/200) | 430 | 15.9 |
| Group 3 (5/200 but not 10/200) | 366 | 13.6 |
| Group 4 (10/200 but not 20/200) | 258 | 9.6 |
| Group 5 (20/200) borderline cases | 223 | 8.3 |
| Better than 20/200 through 20/70 | 240 | 8.9 |
| Better than 20/70 | 100 | 3.7 |
| Not reporting vision remaining | 79 | 2.9 |

the percentage transferred to "hereditary" would be markedly increased. The "prenatal" cases should also be investigated for evidences of underlying etiologic factors. Routine Wassermann tests, which are not now required in many schools for the blind, would aid the

ophthalmologist in making diagnoses of prenatal syphilis and would undoubtedly result in classifying many more cases under the "infectious disease" heading.

The number classified as "congenital and hereditary" indicates that these are the cases most in need of attention from the standpoint of prevention. A more

TABLE 3—Causes of Blindness Classification by Etiologic Cause

| Cause of Blindness | Number | Per Cent |
|---|--------------|--------------|
| Infectious diseases | 772 | 28.6 |
| Diphtheria | 3 | 0.1 |
| Gonorrhea (excluding ophthalmia neonatorum) | 6 | 0.2 |

| Congenital and hereditary | 1,382 | 51.1 |
| Prenatal | 1,067 | 39.6 |
| Hereditary and familial | 315 | 11.6 |
| Etiology not specified | 244 | 9.0 |
| Unknown to science | 4 | 0.1 |
| Undetermined by physician | 186 | 6.9 |
| Not specified | 54 | 2.0 |
| Total—All causes | 2,702 | 100.0 |

intensive study of this group, in order to obtain a maximum of information on the etiologic factors involved, seems to be a necessity.

"Infectious diseases" constitute the next largest group (28.6 per cent of the total cases), with ophthalmia neonatorum (10.7 per cent) and syphilis (5.3 per cent) heading the list of specified diseases. We believe that the syphilis figure is greatly understated. Probably some cases of syphilis are concealed in "congenital and hereditary" and "infectious diseases, not specified." More complete data may be obtained on this important point if ophthalmologists will cooperate by giving accurate and detailed information for every case examined.

⁴ Holloway T. B. The New Statistics on Causes of Blindness Among Children. Sight-Saving Rev. 5:13 (March) 1935.
⁵ The relative proportions of the various causes here discussed are typical only of the younger age groups.
⁶ A Standard Classified Nomenclature of Disease Compiled by the National Conference on Nomenclature of Disease. New York, the Commonwealth Fund 1933.

The relation of syphilis to blindness is a subject of which all too little is known. Keyes⁷ stated that a "weighted average of prevalence in the United States based on a compilation of existing material, with due emphasis given to race, social and economic status, and geographical location, would strike a figure somewhere

around 5 per cent as the average prevalence of syphilis in the United States at the present time." Jeans and Cooke⁸ state that the incidence of congenital syphilis among children (under 14 years) is 2 per cent. From studies of the incidence of syphilis in the general population and of syphilis in children it is our belief that, if the Wassermann test were used more as a routine and

adequate treatment were given to syphilitic persons, much unnecessary blindness could be prevented.

That blindness still results from ophthalmia neonatorum is deplorable. Although silver nitrate is apparently an excellent preventive, the problem of prevention should go further back than this. The proper preparation of the birth canal should receive greater consideration and the treatment of gonorrhea⁹ in clinics must be improved. Education in regard to prevention of gonorrhea and the universal use of prophylactic stations are other factors of great importance.

Special mention should be made of the subdivisions appearing under ophthalmia neonatorum (table 3). Our committee wished to obtain statistics for the gonorrheal cases as differentiated from the nongonorrheal cases, but this proved to be impracticable. In the first place, the examiners reported "not specified" in seven of every ten cases, and, from the fact that some examiners reported all their cases as gonorrheal, it is possible that their figures represent their opinion that only the gonorrheal type leads to blindness. Definite information on some of the cases might be obtained by referring to hospital and board of health records.

"Traumatic and chemical injuries" rank third on the list of etiologic causes (7.8 per cent of the total cases). Perhaps the percentage was so small because of the fact that, when the ophthalmologist could not determine the etiology in cases of enucleation and the like, he preferred to classify them as "unspecified" rather than to accept the parent's claim of accident.

"Neoplasms" (2.2 per cent), "noninfectious systemic diseases" (1.2 per cent) and "toxic poisoning" (0.1 per cent) are together responsible for only a small proportion of the total cases. This small percentage is due to the fact that only the younger age groups were included in the results. It should be mentioned also that in 9 per cent of the total cases etiology was "not specified." More intensive investigation into available records would reduce the number of these cases, but this group should be eliminated finally by more adequate primary recording.

Topographic Classification.—For the topographic classification (table 4) the parts of the eye have been used as the eight main headings: (1) eyeball, (2) conjunctiva, (3) cornea, (4) iris and ciliary body, (5) crystalline lens, (6) choroid and retina, (7) optic nerve and (8) vitreous humor. Separate headings are available for types of disorders of the eye occurring frequently enough to warrant them, and at the end of each group have been inserted the items "other affections specified" and "affections not specified."

Disorders involving the entire eyeball constitute the largest group of topographic causes (31 per cent). These are largely the developmental anomalies, e. g., megalophthalmos, microphthalmos, albinism, and the refractive errors. An analysis of this group by etiologic factor indicates that seven of ten of the disorders of the eyeball are "congenital and hereditary" cases, the remainder were due chiefly to "infectious diseases" and to "traumatic and chemical injuries."

Disorders of the lens (cataract 15.7 per cent and dislocated lens 1.4 per cent) comprise the next largest group. These also are almost entirely included in the "congenital and hereditary" group. Only primary cataracts were considered congenital. However, it is possible that some of the cataracts diagnosed as primary are really secondary to uveitis and other inflammatory

9 Goldberg J. A. Personal communication to the authors. March 26 1935.

conditions but could not be so diagnosed because of the lapse of time between the onset of the condition and the examination. This study of the ophthalmologist's recommendations and prognosis indicates that operations for cataract as well as for other conditions have not been carried out in many cases. Even when the visual acuity obtained is disappointing (as it sometimes is in spite of apparently good surgical results), it must be remembered that the smallest improvement in vision is of great value to these blind children. Many of the schools, however, have neither the facilities for surgery and treatments nor adequate procedure to bring the physician's recommendations to the attention of welfare agencies that can arrange for the necessary service. In some cases ophthalmologists are undertaking the corrective work voluntarily, although they are handicapped by lack of funds for providing necessary lenses and also by the lack of proper personnel to do follow-up work in the homes. This is another function which the nurse or social worker could perform.

The "optic nerve" group is next in order of frequency (16.7 per cent). The etiology in these cases is divided as follows: 42 per cent "congenital and hereditary," 27 per cent "infectious diseases," principally syphilis and meningitis, 9 per cent "neoplasms," 5 per cent "traumatic and chemical injuries," 2 per cent "noninfectious systemic diseases," and the remainder not specified. It is probable that some of the cases reported as "optic atrophy" represent the terminal stage of some other eye diseases and should be classified under other headings.

Among the causes affecting the cornea, which include 14.4 per cent of the total cases, ulcerative keratitis appears most often. About two thirds of these cases are due to ophthalmia neonatorum. Interstitial keratitis, amounting to 2.4 per cent of the total cases, is described in most cases as syphilitic in origin.

Diseases of the choroid and retina account for 14.4 per cent of the cases, one third of these were only indefinitely classified as to etiology. They were ascribed to "infectious diseases, not specified" or to "undetermined by physician." The Wassermann reaction is a fairly accurate guide in syphilis, but available tests for the diagnosis of other infections have much less diagnostic importance. This is the reason why focal infection is ignored in one country and tuberculosis is considered the commonest cause of chronic infections, whereas in other countries the emphasis is reversed. Neither opinion has much scientific, bacteriologic or pathologic foundation. Therefore each is essentially a clinical conception. Certain serobacteriologic tests¹⁰ and inoculation of animals may finally furnish more conclusive information.¹¹

Another third were classified as "congenital and hereditary" and the remainder were due principally to specified infectious diseases and trauma. The other groups are not large enough to call for special analysis.

From this analysis it is evident that the assembling of sound and consistent statistical information on the causes of blindness in children may have considerable significance in shaping a program of preventive ophthalmology, in illustrating the effectiveness of preventive methods used, and for teaching purposes.

CONCLUSIONS

1 More ophthalmologic service is required for children in schools for the blind if much blindness is to be prevented and many children are to be removed from the blind group and placed in the seeing and partially seeing classifications. This service should include provision for corrective operations and treatment as well as for examinations. It is important to remember that a large proportion of this group are wards of the state and that, once removed from their home communities, they are usually out of reach of medical service other than the facilities which the institution provides. If improved eye service were available, more accurate etiologic information could be obtained for classifying the cases, on which effective work for the prevention of blindness must be based.

2 If blindness is to be prevented, it seems desirable to make available to the schools the services of a public health nurse or medical social worker with a good knowledge of eye conditions, to supplement the work of the physician. Such a worker could make contacts with parents to obtain their cooperation in necessary treatments, for example, operations and antisyphilitic treatments. She would be in a position also to do preventive work in the homes in which syphilis or hereditary factors are problems.

3 Although ophthalmia neonatorum accounts for only 10.7 per cent of the blindness in the group studied, continued effort should be made to reduce the number of cases of blindness and visual defects arising from this disease. Until a drug has been proved more effective than silver nitrate, its use as a prophylactic should be required. If blindness from this preventable disease is to be decreased, education must be continued in regard to the proper care of the birth canal, the need for improvement in the treatment of gonorrhea in clinics, and the use of prophylactic stations. More careful bacteriologic technic and complete records are needed before the role of the gonococcus, as compared with other bacteria in the cause of ophthalmia neonatorum, can be properly evaluated and adequate preventive measures instituted.

4 Since the hereditary and congenital group apparently accounts for more than 50 per cent of the blindness in these schools for the blind, and since some of this is undoubtedly due to syphilis, it is imperative that the methods of preventing syphilis be improved. More accurate knowledge of the etiologic factors underlying these ocular defects need to be secured before adequate preventive measures can be successfully applied. It seems evident that syphilis plays a larger part in the etiology of these conditions than these statistics indicate.

5 Because syphilis heads the list of specified diseases and accounts for 5.3 per cent of blindness in these schools for the blind and is probably also responsible for a large proportion of blindness now classified as "congenital" or "hereditary," better methods of preventing and treating syphilis must be insisted on. The antepartum care of syphilitic mothers, better treatment of syphilitic diseases in syphilis clinics, eye clinics and hospitals, and better organized social service and follow-up work will aid greatly in reducing the number of children who may become blind from this cause. In addition to searching for eye diseases attributable to syphilis and preventing blindness as a result of this disease, every ophthalmologist should work for a comprehensive plan in each state for the prevention and treatment of syphilis and the education of the public regarding this disease.

6 Diseases of the choroid and retina are responsible for the visual impairment of 14.4 per cent of the children in these schools for the blind. This group includes disseminated chorioretinitis, choroiditis, uveitis and several other conditions that could be classified only indefinitely as to etiology. Excluding the traumatic cases and those due to known infections, it is evident that this group will require much fundamental research before the etiology can be stated specifically and blindness prevented by direct attack on the underlying cause. The Wassermann reaction is a fairly accurate guide in syphilis, but no equally valuable tests are available in the study of tuberculosis and focal infections.

7 Although the percentage of blindness (7.8) attributable to traumatic and chemical injuries is comparatively small among the children studied, the presence of this cause indicates that educational efforts and the improvement of safety devices should be continued.

8 Because the visual acuity in this group was better than 20/200 in 12.6 per cent of the pupils and was above 20/70 in nearly 4 per cent, ophthalmologists should insist that more attention be paid to educational opportunities. Sight-saving classes should be available for children whose visual defects are not serious enough to justify education by tactual methods but who cannot be safely or profitably educated in the regular public school classes.

These statistics on the causes of blindness in schools for the blind in the United States are probably better than those obtained previously. However, this study clearly indicates the need for the cooperation of ophthalmologists and all concerned with eye diseases and blindness in obtaining more reliable statistical information, especially in regard to exact etiology. We believe that members of the Section on Ophthalmology of the American Medical Association will continue to cooperate as they have in the past.

35 East Seventieth Street.

ABSTRACT OF DISCUSSION

DR. ALBERT D. FROST, Columbus, Ohio. The work done by the committee has accomplished a great purpose, for it has brought to the attention of the profession fairly accurate statistics and will do much to stimulate prevention work. The etiologic classification is of the greatest importance and has shown clearly where the prevention program should be concentrated. However, the accurate etiologic factors are the most difficult to obtain with the present methods, as little or no history is obtainable when the child enters the school for the blind. If it were possible to require that all cases of blindness at the onset be reportable to the state boards of health a great step forward would be made. It is during the preschool period that much valuable time is lost from the standpoint both of treatment and of prevention. Ophthalmia neonatorum is fairly well under control, but as a consequence of time consuming red tape necessary to obtain treatment, many eyes are lost. In Ohio there is an emergency fund to provide necessary treatment to avoid lost time while responsibility is being established. Congenital and hereditary diseases could all be decreased in numbers materially by a concerted personal campaign of education in afflicted families. It is through ignorance that many of these families continue to bring blind children into the world, often against their will. One of the greatest obstacles in prevention is the unscrupulous optometrist who deliberately discourages his patient from consulting an ophthalmologist. It seems that nothing can legally be done about it, but in Ohio we have had some cooperation with the state board of optometry in at least bringing censorship on their own offenders. Unfortunately, the state medical boards have no authority to prosecute this form of malpractice. Snellen measurements should not be the sole method of classification, as many children with corrected vision

of less than 20/200 are able to read ordinary print, and, if made to read braille, do so with their eyes. These cases should be placed according to the judgment of the school ophthalmologist. I have never observed any harm done to vision by allowing them to attend sight-saving classes. Uniform case records must be made before accurate statistics can be compiled. The standard form recommended by the committee seems adequate in that it emphasizes the etiologic diagnosis, which is of much greater importance in any prevention program. This form should be universally adopted so that the next census will be as accurate as possible.

DR. S. W. NEWMAYER, Philadelphia. As an ophthalmologist in charge of sight-saving classes of Philadelphia, I thought that there would be a few facts which may be of interest along this line. We have a school population of 275,000 children, and we have 190 children in sight-saving classes. Of these 190 children fifty-eight have a vision of 15/200 or less, and thirty-one of the fifty-eight have a vision of 5/200 or less, and, as can readily be seen, these are potential cases of blindness or many of them are institutional cases. In Philadelphia, we etiologically group their cases into three groups: (1) congenital and hereditary similar to Dr. Berens, but we exclude from this those with myopia, (2) acquired systemic diseases, and (3) ametropia with degenerative changes. Among these 190 cases, fifty-six are due to congenital diseases, twenty-four of which were diagnosed congenital amaurosis. Twelve of these twenty-four patients have a vision of 15/200 or less. There were fifty-seven cases of acquired systemic diseases and seventy-six cases of ametropia with degenerative changes. There were in class 1 and 2, out of a total of 113 patients, fifty-three with a vision of 15/200 or less, and of the fifty-three, the majority of them, to my mind are institutional cases, as we have thirty-one of them with 5/200 vision or less. Valuable statistics and measures for prevention of blindness may be obtained through studies of large groups of school children, especially in large cities. With reference to the eye examinations in schools and corrective operations and treatments, allow me to call attention to the fact that in the state of Pennsylvania there are legal obstacles that forbid the use of any educational appropriations for any such use. The most effective preventive work is within the power of practicing physicians. School doctors and nurses can only recommend consultation with physicians, and they dare not in their work forbid a parent from taking a child for an eye examination or consulting with opticians, optometrists and others. More than 50 per cent of our patients who are recommended for treatment refuse such recommendations. We cannot force it on them. More than 50 per cent of those who do seek consultations go to other than recognized physicians.

DR. T. B. HOLLOWAY, Philadelphia. While one of the chief purposes of this paper is to stimulate effort to secure honest and reliable statistics concerning the etiologic factors that have to do with blindness, it also serves the purpose of illustrating the fact that much relative relief can be given to many who are included within the group regarded as blind, as this pertains to schools for the blind. How splendid it would be if those who seem so vitally interested in preventing the deaths and economic ills that result from war would devote some of their interest to preventing the same disasters that result from the shot and shell of civilization, namely, syphilis and gonorrhea and this pertains to our various types of government, lay organizations, and individuals. Seventy per cent of the 2,700 students under consideration were from 10 to 20 years of age, and it is surprising to note that 12.6 per cent of the whole student body had better vision than 6/60 or 20/200. When possible, this is the group that should be given the advantage of sight-saving methods. Children with better vision than 20/200 do not belong in schools for the blind. In certain localities and certain states there are readily understood reasons why these schools might be appropriate, for example, Arizona, Idaho, New Mexico, Utah and Wyoming have a population about equal to that of Philadelphia. But there are still other states that are proud of their school systems but they fail to realize the importance of providing the best means for these physically handicapped children to 'carry on' in the great industry of youth. As to the advantages of a social worker affiliated with a school for the blind to me there is no question about the

advisability of such a step I believe that in the more densely populated states there are enough mentally handicapped blind children to be brought together in one state school I believe that the average person would be surprised to see the incidence of 511 per cent for the congenital and hereditary conditions While our statistics are not yet assembled, I feel quite certain that the incidence for this group has increased at Overbrook during the last twenty-five years We do not have sufficient knowledge to judge just how many of these cases are preventable We do know that certain disorders occur repeatedly and frequently in certain families and that the children ultimately become wards of the state or of some philanthropic institution to say nothing of receiving a pension for life later on At Overbrook it costs about \$950 a year to educate a blind child Compare that to the cost to the state or a municipality for educating a normal child

Dr. HARRY S GRADLE, Chicago According to the latest United States census there are 64 500 known blind persons That figure is undoubtedly too low, it probably is somewhere between 80,000 and 90 000 The classification of the census is far from complete, more than 20 per cent of cases being of unknown cause A short time ago I estimated that in the light of present knowledge practically 70 per cent of the blindness in the United States today is unnecessary and could be prevented and eliminated in the course of the next generation It is rather up to this section to take the lead in that type of work Dr Berens spoke of the schools Some two years ago four of us made a survey of the Illinois State School for the Blind We found that, of the 246 pupils, 24 per cent were there unnecessarily, their vision being of such a quality that they could continue their education in the seeing world, and that another 25 per cent could be restored to the seeing world by surgical remedial measures In the last two years we have tried to carry out these remedial measures As a result, we have decreased the population of the Illinois School for the Blind by about 40 per cent To take up the space that was left there, the state government gave us authority to introduce two sight-saving classes, available only to children who live in communities that have no sight-saving classes of their own These are brought in, and, although the expense of conducting these classes is greater than the expense of similar classes in the city, still it puts within the range of those who are not so situated the advantages of this education The difference in cost is great It costs in Illinois, I think, about \$960 a year to educate a blind child, whereas the cost of education of a normal child is around \$45 a year Consequently, in going over the schools for the blind in the various states one should keep in mind the possibilities of reducing the population But the prevention of blindness in the children is only a small phase of the work of prevention of blindness throughout the country by far the majority of cases are in adult life and greater attention must be devoted not only to the prevention but to the remedying of blindness before we can really hold up our heads as a forward-looking nation

Dr. E V L BROWN, Chicago I wish to speak from an educational and ophthalmologic point of view regarding the possible use of smaller print for sight-saving class work than the large 24 point now in use, and to urge a trial of a smaller size of type, namely, 18 point The 24 point type measures about three sixteenths inch in height and the 18 point is definitely smaller In my opinion pupils with stationary conditions such as scarred corneas, aphakia and optic nerve atrophy cannot possibly be harmed by the most strenuous use of their eyes, any more than can one hurt a scarred hand by using it Meissner has reported on the use by twenty two pupils of ordinary print through five school years Many of these pupils had less than 01 vision I have translated and published this report and would be glad to send it to any one interested

Mr. LESLIE PATON, London, D 1, England I wish to stress the necessity for cooperation between all the national societies of the blind We had a meeting a few weeks ago in London, attended by Mr Carris Dr Park Lewis and representatives from different national societies all over the world I happen to be a member of the National Society for the Prevention of Blindness in London, financed by the Cloth Workers Company and by the National Institute for the Blind All together, I have had a good deal to do in recent years with this question

of the prevention of blindness I think that it was Dr Gradle who said that the number of blind that had to be dealt with in this country was 65,000 We have a very much smaller population in Great Britain, but we already have registered papers from 66,000 These haven't all been investigated, myself and my colleagues have gone through about 5,000 of them and we have the prospect of the remaining 60,000 to investigate I am afraid we shall have to issue a preliminary report before we finish I think that the reason of the difference in the numbers may be due to the fact that we have a blind pension scheme in Great Britain, and every registered blind person gets, I think, ten shillings a week I don't think you have a similar scheme Have you? Possibly that is a very natural explanation for the difference between the two numbers Priestley Smith and I were the originators of the definition which secures admission to that blind pension scheme, and it was an extraordinarily difficult thing to devise a practical definition It wasn't any good saying that a person has one eye 6/60 and the other 6/30, because some of these might get on very well, and others with much better central vision but a limited field would be much worse off than these people with good fields and 6/36 So many different factors enter into the determination of the visual efficiency of the individual that any numerical definition becomes unfair Consequently, the definition that we ultimately adopted was too blind to be able to perform work for which eyesight is usually essential" It leaves us a fairly wide scope Of course it does sometimes come to putting down the eyesight in terms of visual acuity, but it allows a freedom of choice which is not given by any other method of definition, and it has worked fairly well on the whole

Mr. LEWIS H CARRIS, New York I merely want to express the appreciation of the National Society for the Prevention of Blindness to the members of this section for the fine cooperation which you have given to the Committee on Statistics of the Blind in assembling these data We do not feel that the eyes of children with congenital anomalies can be harmed by the reading of small print but we always say that, if limitations are to be put on the use of the eyes, this should be decided in individual cases by the attending ophthalmologist In connection with Dr Gradle's discussion, it is my understanding that the Census Bureau will omit all statistics on causes of blindness from any future census, leaving this field of activity to the Committee on Statistics of the Blind The committee is a joint effort of the American Foundation for the Blind and the National Society for the Prevention of Blindness, but it is independent of both organizations If any of you have not had the publications of this committee, we shall be glad to send them to you on request It has been my opportunity in the last few years to visit many parts of the United States and to cooperate with ophthalmologists and state health boards May I express on behalf of the national society our appreciation for the uniform courtesy which you have always extended to the members of our staff on our visits to you in your offices

Dr. TRYGVE GUNDERSEN, Boston As a field worker in one of the large schools for the blind in this country I should like to point out a few of the points that come up in the course of the year's work I began at Perkins Institution one year ago The first thing that confronted me was that I was completely unable to get an ocular history from the patient This difficulty has been largely overcome with the help of a well trained medical social worker and furthermore by incorporating in each application blank questions that will furnish better ocular histories in the future One large group of patients that I immediately encountered consisted of those who had entered this institution with a diagnosis of congenital amblyopia I found that a small number of these patients had completely normal fundi, but on examining their histories I made the interesting observation that birth injuries and convulsions were associated with a great many I believe that this immediately takes these cases out of the classification of hereditary blindness and puts them into the classification of birth injuries The remainder of this large group were found to have retinitis pigmentosa, when the fundi were more carefully examined after mydriasis At the onset of this work I expected that one large branch of the service would be devoted to restoration of vision and the other to conservation of vision I found that the work

consisted practically of the latter only. By more careful examination of the patients I believe that the number of operations performed for glaucoma has been increased at least 100 per cent.

DR. V. M. HICKS, Raleigh, N. C. For fourteen years I have been ophthalmologist for the North Carolina schools for the blind. We all recognize that, from a financial standpoint, our states are responsible in this problem. However, active interest in the problem from a scientific standpoint has been definitely lacking. A few connected with the schools have shown interest, but the profession as a whole has shown the interest of the lay person. It is our duty as ophthalmologists to sponsor in an active way the problem that confronts these children. Schools for the blind sponsored and maintained by the states should be the active workhouse for this problem. More than education of blind children is needed. In North Carolina, in addition to the school, we have developed our hospital and have a medical and surgical staff connected with the institution. Also, we have a gymnasium and swimming pool and other facilities that have been practical in developing these children. I think that it is imperative that this work be centralized, that it be compulsory and that it be actively supported by us in our interests and by the states with their money. Our school is a part of the public school system in North Carolina. Work in an institutional way should frequently be begun before the age of 6 if blindness is to be prevented. Congenital blindness can be solved when enough information is at hand to give positive advice as to the best way out. In our schools in North Carolina more than one third of the population are children whose parents, either one or both, attended a similar institution. These parents do not want to give birth to blind children, but they have not had any advice, and it is natural to find from three to ten children coming into our institution from a mother who was educated there and married for her rightful companionship. Therefore, I believe that it is the duty of this section, and the duty of the specialty of ophthalmology, to give to the states positive information as to what should be done, and I am satisfied that they will act accordingly.

DR. CONRAD BERENS, New York. It is possible that more cases are studied in England than here. However, we have decided to begin with a smaller select group before investigating the larger field. Mr. Paton speaks of having found 65,000 blind persons in Great Britain. Dr. Gradle quoted the census figures showing approximately the same number in the United States. I believe census counts are generally incomplete and that there are actually about 120,000 since the ratio is approximately one blind person in a thousand of the population. Mr. Paton also spoke of the question of pensions for the blind. We have a similar pension system in a few of our states. Dr. Holloway mentioned the importance of sight-saving classes. In the schools for the blind included in our study, there are only two of these classes. Certainly more of them are needed in the schools, or, preferably, the partially seeing children in the schools should be referred to outside classes. In a study of the subject last winter, Hathaway and I concluded that the need for many more of these sight-saving classes was imperative. Dr. Hicks was too modest to say anything of the splendid work he has done. I know that he has been able to help a great many children in his school. Some of these should not have been admitted, some should have been operated on before, and some have been given proper lenses or other appropriate treatment. Dr. Frost spoke of the need for an emergency fund to provide treatment for ophthalmia neonatorum cases while the responsibility for their care is being determined. Such a fund has been established in the state of New York. Dr. Newmayer mentioned the sight-saving classes in the schools and the fact that more than 50 per cent of the children for whom treatment was recommended received no medical care or care administered by nonmedical persons. It is unfortunate that we cannot prevent treatment by nonmedical persons of certain pupils who require scientific care. I do believe, as Dr. Brown does that possibly in some cases children could be permitted to read smaller print. However, we need the active cooperation of ophthalmologists in every case in which special exceptions are made, and this is sometimes difficult to obtain. This is due to lack of interest at times. As Dr. Hicks has said, ophthalmologists should consider these schools as workhouses not just as places to observe interesting blind people.

SUSCEPTIBILITY AND IMMUNITY

IN RELATION TO VACCINATION IN ACUTE ANTERIOR
POLIOMYELITIS

JOHN A. KOLMER, M.D., Sc.D.

Professor of Medicine Temple University School of Medicine
Director, Research Institute of Cutaneous Medicine

PHILADELPHIA

Is it worth while to attempt vaccination against acute anterior poliomyelitis in view of the low attack rate of the disease? If so, what are the prospects of success attending such efforts since the disease is evidently caused by a virus probably multiplying on or in the susceptible anterior horn cells of the spinal cord and causing the pronounced signs of disease only when coming in contact with such cells? Is it likely that antibody produced in human beings by vaccine of spinal cords of monkeys infected with remote passage virus will protect against the disease? If this appears possible, how should the vaccine be prepared? And if it is found possible to vaccinate human beings safely and effectively against poliomyelitis with such vaccine, how should the method be applied as a practical procedure? These and additional problems of related interest are briefly discussed herewith as the basis of my efforts to evolve a safe and effective method of active immunization against the disease.

IMMUNITY IN VIRUS DISEASES IN RELATION TO VACCINATION AGAINST POLIOMYELITIS

In the first place, the fact that an attack of acute anterior poliomyelitis almost invariably results in a lasting immunity against the disease constitutes the main reason for believing and hoping that it may be possible to vaccinate against it safely and effectively. Quigley¹ has recently collected but fourteen cases of second attacks from the literature, of which he believes that eleven appear reasonably definite and he added one case of his own. This indicates that the virus is capable of engendering an active and lasting immunity in human beings, which has been substantiated by the finding of specific neutralizing antibody in the blood of the majority of recovered individuals as well as by the demonstration of acquired immunity in monkeys recovering from the disease produced by intranasal or intracerebral inoculations of virus.

Indeed, it would appear that the majority of diseases caused by viruses are followed by lasting immunity as, for example, in smallpox, chickenpox, rabies, measles, mumps and yellow fever among human beings, and cattle plague, swine fever and dog distemper among the lower animals. Furthermore, it would appear that the majority of viruses are peculiarly capable of immunizing agents not only during an attack of disease but likewise when administered as vaccines, as indicated by the success attending vaccination against smallpox and rabies as well as against dog distemper, cattle plague, African horse sickness, fowlpox, yellow fever and psittacosis. Since acute anterior poliomyelitis is regarded as a virus disease, all this lends great encouragement to efforts for evolving a safe and efficient method for vaccination against it.

From the Research Institute of Cutaneous Medicine and the Department of Medicine of Temple University.

Read before the Section on Pathology and Physiology at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1955.

Owing to lack of space this article has been abbreviated as it appears here. The complete article will appear in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

INCIDENCE AND SUSCEPTIBILITY IN RELATION TO
VACCINATION AGAINST POLIOMYELITIS

Further impetus to such efforts is given not only because the disease is known to be world wide in distribution but likewise because the mortality has varied from 73 to as much as 43 per cent in different epidemics, with as high as from 25 to 45 per cent of residual or permanent paralysis among those fortunate enough to survive. Indeed, there are but few diseases capable of creating as much fear among physicians and the public alike as an epidemic of acute anterior poliomyelitis not only because of the death rate but likewise because of the crippling that may follow an attack of the disease.

Unfortunately, our information on how the virus is spread and epidemics produced is still inadequate, but it would appear, as stated by Flexner,² that it is largely distributed by carriers and that the portal of entry is the upper respiratory tract. Toomey³ has recently renewed interest in the possibility of the gastro-intestinal tract being a portal of entry and in Sicard's thought that the virus may be absorbed by the gray fibers of the intestine and conducted by way of the sympathetic nerves to the spinal cord. For my own part, however, I have not yet succeeded in producing the disease in *Macacus rhesus* monkeys by feeding the virus, nor have Miss Rule and I been able to vaccinate monkeys by this route of administration.⁴

The majority of new-born infants appear to possess a natural and temporary immunity to the virus, as indicated not only by the low attack rate in infants under 1 year of age (35 per cent in the 1916 New York City epidemic) but likewise because Aycock and Kramer⁵ found that the serums of 83 per cent of umbilical cord specimens of blood contained neutralizing antibody for the virus presumably passively transferred from the mothers. However, as shown in table 1, this passive immunity appears to be of short duration as the results of neutralization tests with the serums of twenty-nine children under 4 years of age have shown that from 58.3 to 100 per cent (average, 79.2 per cent) did not contain appreciable amounts of antibody in the blood and on the basis of these serum neutralization tests were to be regarded as susceptible to infection. In our own tests with the serums of nine children under 4 years of age 77.7 per cent failed to neutralize passage virus and thereby proved susceptible.

Among 159 children from 5 to 14 years of age the percentage of serums failing to neutralize virus has varied according to different investigators from 17 per cent to 100 per cent (average, 45.5 per cent). As Aycock and Kramer have shown, the percentage is always higher among children reared in urban than in rural districts. In our own series of twenty children included in this age group, all being reared in Philadelphia, the serums of 40 per cent gave negative monkey neutralization tests and were presumably susceptible.

Among 128 individuals over 15 years of age the percentage of serums failing to neutralize virus and thereby presumably indicating susceptibility has varied from 11.1 to 60, according to different investigators, with a general average of 24.7 per cent. As in the case of

children, Aycock and Kramer have found the highest percentage of susceptibles in the rural districts, but in general terms it would appear that from 60 to 70 per cent of adults have neutralizing antibody in the blood presumably sufficient for conferring some resistance to infection.

Under the circumstances it must be admitted that, except for new-born infants, a large percentage of children are susceptible to poliomyelitis, especially those under 10 years of age, and that the low attack rate among them under "normal" conditions is not due so much to the presence of immunity as to factors influencing the virulence and dissemination of the virus over which we have at present little control and concerning which our information is even less satisfactory. Certainly no community, in the United States at least, can feel secure against the disease, and since the percentage of susceptible children is always high, the attack rate, mortality and residual paralysis can always be expected to increase sharply in the presence of factors increasing the virulence of virus or whatever it is that produces epidemics of the disease. Under these circumstances and because our information on the epidemiology of the disease is still incomplete, coupled with the knowledge that it is known to strike the lowly and well-to-do alike under most unusual conditions despite even rigid precautions against infection, I believe that there is a place of real value for the vaccination of children if a safe and practical method is available for producing sufficient immunity to tide them over to maturity, even though we omit adults on the basis that from 60 to 70 per cent may have lived long enough to acquire resistance to the disease.

THE NATURE OF IMMUNITY IN POLIOMYELITIS
IN RELATION TO VACCINATION

As first shown by Netter and Levaditi⁶ in 1910, the serums of individuals recovering from poliomyelitis contain the antibody capable of neutralizing *in vitro* monkey passage virus and since that time have become the best known antibody identified with the disease.

But it is a mistake to assume that this humoral antibody occurs in all persons who have recovered, so far at least as the neutralization of monkey passage virus is concerned. I have summarized the results reported by various investigators in table 2, in which it will be noted that from 12.1 to as high as 63.6 per cent (average, 34.9 per cent) of the serums of 126 individuals recovering from poliomyelitis failed to neutralize the virus *in vitro*, presumably because the antibody was absent or present in insufficient amounts. It is for this reason that several investigators have cautioned against the assumption that the serums of all convalescents and patients who have recovered are fit for the serum prophylaxis or treatment of the disease.

And yet, as previously stated, the immunity following an attack is quite solid, since second attacks are so rare. It is therefore suggested that there is probably an important cellular or tissue immunity in many individuals who have recovered who do not show demonstrable amounts of antibody in their serum.

Therefore, since it is possible for the serums of patients who have recovered to give negative monkey neutralization tests, despite the evidence for the existence of immunity, I was well prepared to observe that the serums of some children vaccinated by my method failed to develop this type of antibody and indeed this

happened in four children of the original group.⁷ Whether these children have a tissue immunity or are susceptible still remains to be seen. On the other hand, the presence of the antibody is widely accepted as indicative of immunity and I do not know of any individual carrying antibody in the blood who has contracted poliomyelitis. The nature of this assumed tissue immunity is unknown but it has occurred to me that the body cells may be "tuned up" for the rapid production of antibody when virus gains access to them and that in this manner they may escape infection. But since the attack rate is so sharply increased during epidemics, presumably because of greatly enhanced virulence of the virus, it seems to me highly desirable to vaccinate children under 12 years of age.

Suggestive of the existence of tissue immunity is the observation made during the past year by Miss Rule and myself that the serums of normal guinea-pigs and rabbits do not contain neutralizing antibody for our monkey passage virus, though as is well known these animals possess an absolute immunity to the virus. At least we have never been able to infect these animals by intracerebral inoculation,⁸ and Harmon, Shaughnessy and Gordon⁹ have had a similar experience with them as well as with young dogs, cats, mice, young hogs, lambs and calves. In this connection mention may also be made that in certain other virus diseases (dog distemper, fowl plague, fowlpox, African horse sickness, foot and mouth disease and horse encephalitis) various investigators have found neutralizing antibodies either absent or but irregularly present in the blood of natural hosts that have been recovered, even though these infections generally engender a high state of immunity.

Since, however, it appears that the presence of large amounts of neutralizing antibody in the blood is indicative of immunity even though its absence is not inconsistent with this state, one can only guess at its origin. Aycock and Kramer have long maintained that it develops because of a widespread distribution of the virus with a process of natural immunization as the result of single or repeated subclinical or unrecognized attacks. This has always impressed me as a very reasonable assumption and encourages one to seek an efficient method for vaccinating human beings. For if it is possible for immunity to be engendered by so light an infection, it ought to be possible to duplicate the results by vaccination.

Since tissue immunity apparently exerts an important role in resistance to and recovery from poliomyelitis, it is to be expected that various other theories of immunity to this disease would be entertained. In this connection Draper¹⁰ has thought that a certain constitutional make-up of young children (broad brow and round face with wide space between the eyes, plumpness, separation of central incisor teeth with difficult dentition, and so on) indicated unusual susceptibility. Aycock also has observed that unusually well developed children, who are however of a more delicate make-up physically and temperamentally than normal children, may be more susceptible than usual. Indeed, Aycock¹¹ believes that some variation in the physiologic activity of the body may produce an increased resistance to poliomyelitis without outside assistance by way of unrecognized infection with virus, for which he has

proposed the name "autarcosis", Jungeblut and Engle¹² offer the suggestion that the mass protection enjoyed by the adult human population may rest primarily on the normal functions of the endocrine balance characteristic of mature age.

It is stated that old monkeys carefully guarded against chance exposure to the virus are more resistant than young animals (which our experience confirms) and it would appear that there is much that is not understood about this subject, so commonly discussed as "maturation immunity". The fact remains, however, that large numbers of young children, and adults as well, contract poliomyelitis every year and either die of the disease or recover with varying degrees of permanent crippling. A safe and efficient vaccine, therefore, is highly desirable, particularly for the period of childhood, until the natural agencies of resistance, whatever they may be, have been developed.

Certainly I cannot agree with those who believe that dependence can be placed on the processes of natural immunization or maturation alone in view of the low attack rate of acute poliomyelitis, because I believe that it may be possible to protect children safely and efficiently by vaccination over the period of their greatest susceptibility.

THE ANTIBODY FOR MONKEY PASSAGE VIRUS IN RELATION TO VACCINATION

But since the only practical source of vaccine for immunization against poliomyelitis is the spinal cords of monkeys infected with remote passage virus, there is at once the important question whether or not the antibody produced by such virus will aid in the protection of human beings against the disease. In other words, does the species of animal furnishing the vaccine alter it in such a way that the antibody produced may fail to protect human beings against poliomyelitis?

Of course it is irrefutably established that vaccine of the cowpox virus, which is presumably the smallpox virus passed through the skin of calves, will protect human beings against smallpox. Furthermore, it is definitely established that vaccines of rabies virus passed through the spinal cords of rabbits will temporarily immunize both human beings and dogs. It also appears that vaccines prepared from the brains of mice infected with the yellow fever virus immunize human beings against that disease, as shown by Hindle¹³ and others. In addition, the successful vaccination of human beings by Rivers and Schwenker¹⁴ with vaccines of the living virus of psittacosis, or parrot disease, prepared from the livers and spleens of infected mice, indicates that the passage of viruses through lower animals leaves their vaccines capable of engendering immunity in human beings. From these instances one might infer that vaccines of remote monkey passage poliomyelitis virus will immunize not only monkeys but human beings as well.

However, as shown by Paul and Trask,¹⁵ the experimental disease produced in monkeys by two human strains of virus did not leave these animals on recovery immune to passage virus and in a few instances recovery from infection with passage virus left the animals susceptible to human virus. Furthermore, the antibody in some human convalescent serums for human virus

appeared to differ qualitatively for passage virus Weyer¹⁶ has found also that the serums of horses immunized with monkey passage virus was highly neutralizing for passage virus (1 500) but much less so for human virus (1 20). However, Howitt¹⁷ and others have found that serums from horses, goats and sheep immunized over a long period of time with monkey passage virus have given some evidence of therapeutic value in a small group of human cases in the paralytic stage of poliomyelitis, indicating that the antibody produced by passage virus is capable of neutralizing human virus. Furthermore, as shown by Flexner,¹⁸ human convalescent serum neutralizes not only recent but also remote passage virus, thereby indicating that frequent passage of the virus through monkeys does not produce material alteration but also that monkeys vaccinated by remote passage virus develop immunity in part at least to recent human virus.

It would appear, therefore, that the weight of evidence available at present indicates that the antibody produced in human beings by a vaccine of remote monkey passage virus may aid in protection against the human disease, as it probably aids in the protection of monkeys themselves, but the final answer to this question of fundamental importance must await the results of vaccination of human beings and especially those exposed to epidemics of the disease. The vaccine should be highly successful, as Miss Rule and I have found that the serums of children immunized in Philadelphia by my attenuated vaccine of remote monkey passage virus (Rockefeller strain) have completely neutralized human spinal cord virus (Cuneo) sent me by Dr J F Kessel from the 1934 epidemic in southern California as well as the virus in the third monkey passage from another fatal human case in the same epidemic, kindly furnished by Miss Beatrice Howitt of San Francisco. No one knows at present whether or not immunologically specific strains of poliomyelitis virus exist. If they do, the problem of vaccination would be greatly complicated in proportion to the number of strains, just as vaccination against the pneumococcus has been complicated by the known existence of so many different types.

THE METHOD OF PREPARATION OF VACCINE IN RELATION TO IMMUNIZATION

If, therefore, encouragement exists for the immunization of human beings against poliomyelitis with vaccine of remote monkey passage virus, the question arises as to the best manner for preparing it of monkey spinal cord for the safe and effective vaccination of human beings.

As stated by Andrewes,¹⁹ it would appear definitely established that vaccines of dead viruses are enormously weaker than living and attenuated viruses, because the former contain but small amounts of antigenic virus protein while the virus in the latter after injection can multiply perhaps a millionfold in the body and thereby have a far better chance of producing resistance. Furthermore, as recently stated by Rivers²⁰ it would appear that the lasting immunity of virus diseases may be due to the prolonged or persistent sojourn of the viruses in hosts once infected, and if this is true of

poliomyelitis, it is not at all likely that completely "killed" vaccines could produce a durable immunity in this disease.

While vaccines of various viruses apparently inactivated or killed by solution of formaldehyde, phenol, chloroform, ether, heat and other agents have been used with some success in vaccination against rabies, distemper, cattle plague and fowlpox, yet, as stated by Andrewes and more recently by Rivers, it is still an open question with at least some of these vaccines whether or not the viruses are really killed or only attenuated because it is almost impossible at present to determine when a virus has been completely inactivated. In poliomyelitis of monkeys, at least, best results have been obtained with subcutaneous or intracutaneous injections of the living virus by Flexner and Lewis,²¹ Aycock and Kagan,²² Stewart and Rhoads,²³ Rhoads²⁴ and others or by mixtures of virus and immune serum given together or separately. Miss Rule and I were unable to vaccinate monkeys successfully with chloroform and heat inactivated vaccines⁴ and for these reasons I have thought that best results in the immunization of human beings might probably be obtained, as they have in monkeys, with vaccines of living virus, provided a way could be found for safely attenuating the virus.

Of the several agents employed for the inactivation of virus in the preparation of poliomyelitis vaccine, solution of formaldehyde would appear to be of most interest, since it has been used with success in the preparation of diphtheria and tetanus toxoids and other vaccines. Apparently, however, one has to work within a fairly narrow range of concentration of the solution, as too much seems to destroy all antigenic power and too little will not completely inactivate. As stated by Andrewes this is one of the facts which lead some to suspect that an effective vaccine may be not entirely "dead." However, it may be that a large dose of dead virus will immunize as effectively as a small dose of living but attenuated virus, but this is not at all likely. Further, Dunkin and Laidlaw²⁵ have shown that formaldehyde treated canine distemper virus produces only a fleeting immunity in dogs and that an active virus must be employed for obtaining a solid lasting immunity. As stated by Rivers, all the evidence at hand seems to indicate that whatever immunity is produced by inactivated viruses endures only for a relatively short time and that many workers do not seem to be disturbed by this fact, which is so important with vaccines expensive to make and difficult to administer. Furthermore, as suggested by Sabin,²⁶ the antigens engendering the production of neutralizing antibodies may not exist in the viruses but arise from the infected tissues, which, if true, would indicate the need of using active virus in vaccine.

ATTENUATION OF VIRUS

Believing therefore that effective vaccination against infantile paralysis required the administration of active virus, I became interested in the possibility of using living but attenuated remote monkey passage virus and in the course of some chemotherapeutic investigations²⁷

with sodium ricinoleate, which possesses some detoxifying activity, I considered the possibility of this agent so attenuating the virus as to make it safe for subcutaneous injection, especially since McKinley and Larson²⁸ had already found that monkeys could be sometimes immunized by intraperitoneal injections of this type of vaccine

Miss Rule and I⁴ prepared a vaccine of a 1 per cent emulsion of monkey spinal cord in sterile water with sufficient sodium ricinoleate to give a 10 per cent concentration and in a series of six monkeys succeeded in vaccinating two successfully and one partially. Believing that better results could be obtained with vaccines carrying more tissue-virus and less sodium ricinoleate, we then prepared vaccines carrying 4 per cent of virus with 1 per cent sodium ricinoleate²⁹ and successfully vaccinated eighteen monkeys with subcutaneous and intracutaneous injections,³⁰ since all animals inoculated intracerebrally about one month later with about eighteen minimal infective doses of virus remained perfectly well, whereas the controls developed poliomyelitis in from five to nine days

The virus in the vaccines, however, was not killed, since the injection of 0.3 cc amounts into the brains of monkeys produced paralysis, but usually milder and with a somewhat longer incubation period, suggesting that the sodium ricinoleate may have produced some attenuation, although this is very difficult to determine in view of the varying susceptibility of monkeys to the virus

But furthermore, and very importantly, the subcutaneous and intracutaneous injection into these eighteen monkeys of from five to ten doses of 0.05 to 1 cc per kilogram and amounting to as much as a total of from 5 to 100 cc for a child of 10 Kg (about twenty-five pounds) were without any ill effects whatever aside from local irritation at the sites of injection, which I thought acceptable as possible further evidence of attenuation of the virus³¹

Under these circumstances Miss Rule and I felt justified and safe in taking the vaccine ourselves in July 1934, even though we were without neutralizing antibody in the blood. We both took 0.5, 1.5 and 2 cc. at five-day intervals with no ill effects aside from local irritation at the sites of injection in the arms. Two weeks after the third dose we found our blood containing antibody, as determined by the serum neutralization tests with monkeys in which 0.2 cc of serum mixed with 0.2 cc of 5 per cent virus was injected intracerebrally after standing two hours at 37 C

Furthermore, I was impressed with additional possible factors of safety, namely, the administration of a small first dose followed by two additional doses at weekly intervals, the rapidity with which antibody is apparently produced by this vaccine in both human

beings³² and monkeys,³³ and the subcutaneous route of administration, since it is difficult to infect monkeys by this route even though the virus has been well adapted to this animal³⁴

In addition I have thought that the remote monkey passage virus employed in the preparation of the vaccine may have lost to a large extent its virulence for human beings as a result of a very large number of passages through monkeys during the past many years after the manner of the loss of virulence of the small pox virus by reason of passage through calves and other of the lower animals. Certainly it is difficult to infect monkeys with human spinal cord virus even by intracerebral inoculation, and ordinarily many passages are required before virus becomes highly virulent for these animals and I have thought that the reverse may be equally true³⁵

Under the circumstances I regarded the vaccine as so safe that I administered it to my two sons, aged 11 and 15 years respectively, the former being without neutralizing antibody in his blood. Since then Dr Klugh, Miss Rule and I have given from one to three doses of the vaccine at weekly intervals by subcutaneous injection to a group of twenty-three additional children varying in age from 8 months to 11 years, at the request or with the consent of their parents, with absolutely no ill effects aside from occasional mild constitutional and local reactions at the sites of injection corresponding to those produced by diphtheria toxoid. All children were selected on the basis of preliminary monkey serum neutralization tests and the results, which are given elsewhere,³² have shown antibody production in 84 per cent

I believe, therefore, that sterile vaccine carrying 4 per cent of very finely divided remote monkey passage spinal cord virus is safe by subcutaneous injection for both monkeys and human beings after treatment with 50 per cent glycerol for one week and 1 per cent sodium ricinoleate and 1/80,000 phenyl mercury nitrate at 37 C for twenty-four hours followed by from ten to fourteen days in a refrigerator at 12 to 16 C. It is likely that weak concentrations of solution of formaldehyde, phenol and other chemical agents may also attenuate the virus just as effectively as sodium ricinoleate³⁶

It is true that the three doses advised for human beings³² are much less per kilogram of weight than found necessary for the effective immunization of monkeys but it is a reasonable assumption that human beings will require much less protection than monkeys infected intracerebrally with ten or more minimal doses of virus or by repeated intranasal inoculations. Furthermore, the doses advised were decided on in the interests of safety until more data were available.

28 McKinley J. C. and Larson W. P. *Proc. Soc. Exper. Biol. & Med.* 24: 297 (Jan.) 1927

29 The vaccine is now prepared with the addition of 1/80,000 phenyl mercury nitrate to prevent accidental bacterial contamination during its preparation and administration since 1 per cent sodium ricinoleate is very low in bacteriostatic and bactericidal activity. The brain and spinal cord of each monkey is also tested for the virus of lymphocytic choriomeningitis (Armstrong and Lillie) before the latter is used in the preparation of vaccine. The details of preparation are described by Kolmer J. A. and Rule, Anna M. *An Improved Method for Preparing the Kolmer Poliomyelitis Vaccine with a Note on Its Administration and Safety* J. Am. Pub. Health A. to be published

30 Kolmer J. A. *Am. J. M. Sc.* 188: 510 (Oct.) 1934

31 Since then twenty-four additional monkeys have received five subcutaneous injections of the 4 per cent vaccine at five-day intervals in a dose of 0.5 cc. per kilogram without any evidences of poliomyelitis infection whereas in a series of twenty monkeys receiving similar subcutaneous injections of the straight virus (five doses of 0.2 cc. of 10 per cent virus per kilogram) poliomyelitis developed in one again suggesting that the virus had probably undergone some attenuation in the vaccine

32 Kolmer J. A., Klugh George Jr. and Rule, Anna M. *A Successful Method for Vaccination Against Acute Anterior Poliomyelitis*, J. A. M. A. 104: 456 (Feb. 9) 1935

33 Kolmer J. A. and Rule, Anna M. *Am. J. Clin. Path.* 5: 349 (Sept.) 1935

34 In this connection Dr. William H. Park has recently stated "It is known that when intradermal or subcutaneous methods of injection are used it is difficult to infect monkeys. There is every reason to believe that this is true of children (From the *Crippled Child*" 13: 57 1935)

35 It would appear that Dr. Park also shares this opinion as recently stated. It is also known that it is difficult to adapt the human virus of infantile paralysis to monkeys so that they will develop an attack. The reverse of this is probably true that a virus adapted to infect monkeys has lost much of its virulence for man. (From the *Crippled Child*)

36 In this connection I may state however that the addition of 1/4,000 solution of formaldehyde to the vaccine has resulted in so much inactivation of virus that monkeys could not be immunized by five subcutaneous injections at five day intervals of doses varying from 0.05 to 0.5 cc per kilogram 1/100 phenol and 1/40,000 mercurphen also resulted in some inactivation so that both were less vaccinogenic than the plain ricinoleated vaccine and that carrying 1/80,000 phenyl mercury nitrate (Kolmer and Rule article mentioned in footnote 29)

Just how long the immunity lasts is impossible to state at present, except to mention that monkeys vaccinated about three years ago are still solidly immune to intracerebral injections of virus³⁷. It is likely, however, that some of this resistance may be due to the increasing age of the animals (maturation immunity). Certainly it is reasonable to expect that the immunity engendered by attenuated virus will endure much longer than that produced by "dead" virus and I am hoping that future experience will show that it will suffice at least to protect the majority of children over their age of greatest susceptibility.

THE PRACTICAL APPLICATION OF VACCINATION AGAINST POLIOMYELITIS

But it may be argued that vaccination of young children may deprive them of the opportunity of natural immunization through acquiring subclinical or abortive attacks of the disease which Aycock and others believe are largely responsible for the immunity that is apparent in a large percentage of adults. This is probably based on the assumption that antibody produced by vaccine will prevent infection with virus and thereby prevent the latter from producing immunity. This may be true, but I myself do not care how children and adults as well acquire immunity as long as they safely do so in sufficient degree to protect them against the disease. Protection before natural immunization can occur and especially in times of epidemics seems a more important desideratum than a possible immunity obtained from a hypothetical abortive attack.

As previously stated, antibody production appears to be sufficiently prompt even after the first dose of vaccine to indicate that it may be safely used in epidemics³⁸.

But, since the attack rate is so low in the absence of epidemics, should all children be vaccinated? Unfortunately, there does not exist at present a cheap and quick method for picking out susceptibles, the monkey serum neutralization test for antibody being the only one available. The colloidal gold test of Eberson as well as complement fixation, precipitin and skin tests conducted by Dr Klugh, Miss Rule and myself have proved disappointing, as reported elsewhere³⁹. Schultz, Clifton, Gebhardt and Chambers⁴⁰ had previously found the colloidal gold test of no value as likewise skin reactions by Sabin, Park and Jungeblut⁴¹. It would appear that the monkey is the only animal known at present to be susceptible for antibody tests and it is

too expensive for use on a large scale. Furthermore, the tests require from two to three weeks. Certainly such tests are not required in the case of children aged 4 years or younger, as enough have been done to show that about 80 per cent are susceptible, and even more in the rural districts.

SUMMARY

1 Since acute anterior poliomyelitis is regarded as a virus disease and results in lasting immunity, second attacks being very rare, and since the majority of the viruses appear to be highly capable immunizing agents, great encouragement is given to efforts for producing a safe and effective method for the vaccination of human beings against the disease.

2 Further impetus to such efforts is given by reason of the fact that the mortality has varied from 7.3 per cent to as much as 43 per cent in different epidemics, with as high as from 25 to 45 per cent residual paralysis.

3 While the attack rate is low, except in epidemics, it would appear that the disease is of increasing frequency both as isolated cases and in epidemics.

4 While about 83 per cent of new-born infants have antibody in the blood temporarily, serum neutralization tests with the serums of twenty-nine children under 4 years of age, including nine of our own series, failed to neutralize the virus in about 79.2 per cent and were apparently susceptible.

5 Among 159 children from 5 to 14 years of age, including twenty of our own series, an average of 45.5 per cent were without neutralizing antibody.

6 Of 128 individuals over 15 years of age and largely composed of adults, the serums of 24.7 per cent failed to neutralize the virus.

7 Under these conditions it would appear highly probable that a large percentage of susceptibles are present in all communities, particularly in the case of children under 12 years of age, thus rendering a safe and effective method of vaccination highly desirable.

8 This need is emphasized also by reason of the fact that the passive immunity conferred by the injection of normal or convalescent serum is of very short duration.

9 From 12.1 to as high as 63.6 per cent (average 34.9 per cent) of the serums of 126 individuals recovering from poliomyelitis have failed to neutralize passage virus, presumably because neutralizing antibody was absent or was present in insufficient amounts. Therefore, not all convalescent serums are fit for prophylactic or therapeutic immunization.

10 While humoral and tissue immunity may be due to unrecognized and subclinical attacks of poliomyelitis, it has been suggested also that there may be a type of "maturation immunity" due to constitutional make-up or undetermined physiologic factors.

11 Even if the neutralizing antibody is due to subclinical or unrecognized attacks of the disease, the ease with which it is apparently produced suggests that vaccine may likewise produce it readily and in a large percentage of susceptible individuals.

12 The processes of natural immunization, whatever they may be, should not be regarded as sufficient, since so many and especially children contract the disease before immunization can develop and either succumb or recover badly crippled and handicapped for the remainder of life.

13 Since vaccines of other viruses prepared from the tissues of lower animals successfully immunize

37 In this connection I may state that the results of monkey serum neutralization tests with twenty three of the original group of twenty five children²² conducted in August (one year after immunization) have shown the persistence of antibody. One child without antibody last year (tested one week after the third dose) was found to have a large amount of antibody this year.

38 But from the outset I have realized the possibility and probability of the vaccine being given during the incubation period too late to abort the disease and with the possibility of having the vaccine blamed for the attack. Since January of this year 446 individuals 319 of whom were children from 6 months to 15 years of age have received the usual three doses at weekly intervals in our clinic at Temple University Hospital with absolutely no ill effects aside from some local reactions. During this period the Research Institute of Cutaneous Medicine has distributed 12,812.5 cc. of the vaccine to 582 physicians in thirty six states mostly in the epidemic areas and the William S. Merrell Company of Cincinnati has distributed an additional 8,910 cc. through 137 physicians. These amounts have been sufficient for the immunization of more than 10,000 individuals (mostly children). No one receiving the three doses has developed the disease nor have I any knowledge of the vaccine producing lymphocytic choriomeningitis or demyelization encephalomyelitis. There have been, however, ten instances of poliomyelitis developing after one or two doses of the vaccine the histories and a more complete analysis of data being given elsewhere (Kolmer, J. A. Am. J. M. Sc. to be published) with the statement that at least some if not all of these appear reasonably certain to have been instances of giving vaccine during the incubation period too late to abort the disease.

human beings, and since horses, goats and sheep immunized over long periods of time with monkey passage virus produce at least small amounts of antibody capable of neutralizing human virus, it would appear probable that vaccines of monkey passage poliomyelitis spinal cord would successfully vaccinate human beings

14 The serums of children immunized in Philadelphia with my vaccine of monkey passage virus have neutralized human spinal cord virus from the 1934 epidemic in California, indicating that antibody produced by vaccine of passage virus is capable of neutralizing human virus

15 It appears definitely established that vaccines of viruses killed by heat or chemical agents are generally much weaker immunizing agents than living or attenuated viruses

16 It is possible, however, that large doses of "dead" virus may be slightly vaccinogenic, provided a method is found for concentrating the virus in order to reduce reactions from injections of spinal cord tissue and diminish the added burden placed on the antibody-producing tissues for protecting themselves against the tissue proteins

17 Filtrates of my vaccine of living but attenuated virus are antigenic, but finely divided suspensions of cord tissue seem preferable, in order to secure the maximum of intracellular virus for immunization. The local reactions are slight and skin tests have shown that human beings have not acquired allergic sensitization to the small amounts of spinal cord protein contained in three doses

18 Monkeys have been successfully vaccinated by subcutaneous and intracutaneous injections of virus or by mixtures of virus and immune serum, but these methods are considered too dangerous for the immunization of human beings

19 We have succeeded in immunizing all of forty-two monkeys with a living but attenuated vaccine carrying 4 per cent emulsions of spinal cord in 1 per cent solutions of sodium ricinoleate with no evidences of ill effects aside from local reactions at the sites of injection. Three doses of the vaccine were then taken by Miss Rule and myself without ill effects and with good antibody response

20 Three doses of the vaccine at weekly intervals were given, with the consent of parents, to twenty-five children varying in age from 8 months to 11 years (the majority of whom gave preliminary negative serum neutralization tests for antibody) with absolutely no ill effects and with antibody response in 84 per cent (During the past ten months 446 additional individuals [mostly children] have been immunized at Temple University Hospital with no ill effects, as likewise about 10,000 additional in thirty-six different states mostly in epidemic areas. No person receiving the three doses has contracted the disease, but ten receiving one or two doses have done so, it would appear that the majority of these may have been instances of vaccine being given during the incubation period too late to abort the disease)

21 Attenuation of the virus in the vaccine along with the fact that the first dose is quite small per body weight, with an interval of at least a week for antibody production before the second and third doses are given, appears to constitute important factors in safety

22 Furthermore, it may be that the remote monkey passage virus used in the preparation of the vaccine is of greatly reduced infectivity for human beings and

that subcutaneous injections represent a portal of entry unsuited to infection, since it is difficult to infect monkeys with the straight virus by this route.

23 In some instances, antibody sufficient for the neutralization of virus has been found in the blood of susceptible children as early as ninety-six hours after the first dose, and in monkeys even large doses per body weight do not appear to lower resistance temporarily by the production of a negative phase.

24 It is not yet possible to state the duration of immunity following vaccination, although monkeys vaccinated three years ago are still immune to intra-cerebral injections of virus (Neutralizing antibody has been found to persist in the blood of children immunized one year ago)

25 If the immunity lasts only a sufficient number of years to protect children over their age of greatest susceptibility until maturation immunity has developed, it would appear that vaccination may be very much worth while

26 At the present time the monkey serum neutralization test is the only reliable one for the detection of humoral immunity. While it is too expensive for routine use on a large scale, it is available for those who can afford it and may be sufficiently reliable as a test for immunity. It is hardly necessary, however, in the case of children under 4 years of age, as about 80 per cent are susceptible

2101 Pine Street.

ABSTRACT OF DISCUSSION

DR. WILLIAM H. PARK, New York. Those of us who are interested in this work are watching with keen interest the vaccines prepared by Drs. Kolmer and Brodie. Both have promising possibilities. We know that the Semple vaccine against rabies is apparently a killed virus and is effective. The results of Dr. Kolmer are very similar to those that we have obtained and it seems therefore that there are two vaccines which are probably both safe, and only time can tell which is the better. I think this generous rivalry between the two will be advantageous. Then, of course, there is Dr. Kramer's vaccine, in which the virus and the serum are mixed together in an adjusted mixture, which is neutralized not fully but sufficiently so as not to produce disease in those injected. I believe that by the end of this summer we shall know which of the first two is to be used, or whether both should be used. It may be that the dead vaccine is better adapted to be sent to a distance, although the live virus probably could be preserved in transit. I think it is a very interesting point Dr. Kolmer has brought out, that this virus, which is still quite virulent in monkeys, is apparently not virulent in children in the small doses advised.

DR. H. F. KRAMER, Brooklyn. I should like to ask Dr. Kolmer how far one can go with the neutralization test. It is a perfectly good test if too much is not asked of it. It has its limitations decidedly. Then, what does the neutralization test mean when it is run? Does it give susceptibility? Does it tell whether the person is immune? It is not, so far as I know, a test of susceptibility. Another question on the neutralization test. Some of those figures that were on the screen indicate that a large proportion of people who have a disease have never developed immunity. The figures giving the highest percentage are the smallest figures. The test wasn't done very often. The rule is good solid immunity following disease. Sometimes one sees an individual who has failed to develop immunity but that is extraordinarily rare.

DR. JOHN A. KOLMER, Philadelphia. The significance of antiviral antibody in relation to susceptibility and immunity in acute anterior poliomyelitis must be discussed with great care in view of the limited number of tests reported, because of the expense involved in using a monkey for each serum neutralization test. For this reason it is highly desirable to discover some cheaper test for this antibody to facilitate inves-

tigation on a broader scale than is now possible. At this time, however, I believe that sufficient antibody in 0.5 cc of serum capable of completely neutralizing at least ten minimal infective doses of virus in an exposure of two hours at 37 C is indicative of sufficient resistance to protect the individual against acute anterior poliomyelitis. Effective resistance may be present, however, without demonstrable amounts of this antibody in the blood. This is suggested by the fact that individuals known to have had poliomyelitis are found without antibody in the blood, as shown in my second chart, and yet clinical experience indicates that they may be nevertheless highly immune, since second attacks are rare. I believe that a tissue immunity may be present with or without humoral immunity. For this reason I believe that the presence of large amounts of this antibody in the blood is indicative of immunity but that its absence does not necessarily indicate susceptibility.

THE MANAGEMENT OF RENAL TUMORS, INCLUDING CYSTS

R. M. LeCOMTE, MD

Professor of Genito-Urinary Surgery Georgetown University
WASHINGTON, D. C.

Malignant growths of the parenchyma of the kidney may be classified broadly, for purposes of management, as hypernephromas and carcinomas, they are seldom distinguishable from each other before operation. Hypernephromas have an irregular cellular structure and are radiosensitive, while carcinomas have a fairly typical microscopic arrangement and are apt to be radioresistant. Apart from their histologic structure, sarcomas and teratomas have practically the same characteristics as hypernephromas. Because of diagnostic difficulties, neoplasms of the kidney pelvis must be included here, they are squamous cell growths, similar in structure to those occurring in the bladder, are not sensitive to the roentgen ray and have just as indefinite an evolution as do vesical tumors.

Long and varied experience has shown that the only curative treatment for malignant neoplasms is removal of the affected kidney and its contained or attached growth, together with such neighboring tissues as may have been infiltrated by it. This has been so well and repeatedly demonstrated that in determining the management of a particular case it is necessary only to decide whether benign as well as malignant neoplasms should be given similar radical treatment, to cite what clinical circumstances contraindicate operation altogether and to give, in brief, the desiderata of the operation itself, together with preoperative and post-operative treatment.

Benign growths of the parenchyma are commonly recognized at necropsy. They are usually small and harmless or, if they do become large enough to produce clinical symptoms, have already caused enough change in the kidney to make them malignant by position if not by cellular structure and metastases. The uncertainty as to what the result may be if they are treated by simple excision and the fact that they cannot be readily submitted to the repeated minor attacks which may be required to eradicate them makes it necessary to treat them by nephrectomy. This is only another way of stating that any renal or pelvic neoplasm that can be recognized clinically should be considered as actually or potentially malignant and treated as such. Benign papillomas of the kidney pelvis might seem to be an exception to this rule, but the difficulty of locating all

the growths that may be present in the finer ramifications of the calices, together with their tendency to recur or for similar growths to appear in new locations, makes it inadvisable to treat them by any more conservative means.

Apart from such self-evident circumstances as poor general condition and severe disease with poor function in the opposite kidney, which would naturally preclude successful nephrectomy, the surgeon confronted with a renal neoplasm must carefully consider whether the local conditions referable to the growth itself are such as to make the prospects for cure by operation sufficient to justify the risk that will be incurred in performing it. Failure to observe this can only lead to discredit both to the surgeon and to the operation. Improved mortality statistics will come from earlier diagnoses and earlier operations rather than from accepting hazardous operative risks. These, in turn, will depend on earlier, more searching and more persistent efforts to determine the cause for hematurias that are not characteristic. The presence of remote metastases, usually in the liver, lungs or bones, ordinarily contraindicate operation, but occasionally an exception may be made and nephrectomy done if hemorrhage is unusually great and not controlled by irradiation and perhaps too if renal pain cannot be otherwise controlled. This is to be done only in a patient whose general condition is exceptionally good despite the presence of the tumor and its local complication.

While no sharp lines can be drawn between the groups, patients with renal tumor may be conveniently arranged as to operability, on the basis of local data, into three classes, first, those that are definitely operable, second, borderline cases and, third, the definitely inoperable ones. The first of these includes patients presenting a small or moderate sized mass that is freely movable with respiration and on palpation. In these it is probable that the growth has not yet broken through its capsule and involved neighboring organs and that surgery may be undertaken with a reasonable chance of complete removal and thus of cure. In this category must be placed those patients whose only symptom is pain and whose only sign tumor, without either hematuria or pyelographic evidence. Such cases occur, as a rule, in children and adolescents and are rare but not unheard of in adults. In them only exploratory operation will disclose definitely the nature of the disease and whether it is operable or not.

To the borderline group belong patients whose tumors are fairly large, whether movable or not. Whether or not to attempt a nephrectomy in these cases will depend on the judgment of the surgeon in charge and in many instances, perhaps in the majority, the question can be settled only after exploratory incision has been made. In operating the surgeon should not hesitate to close the wound, without disturbing the growth, if conditions that will prevent its safe or complete removal are disclosed. It is good surgical judgment not to attempt removal at all in cases obviously inoperable, for severe hemorrhage or rupture of the capsule with dissemination of tumor tissue may be brought about even on slight manipulation. While successful cures occasionally occur after heroic operative procedures in which tumor masses are removed from the renal vein or vena cava, consideration is seldom given to other cases in which death occurs from immediate hemorrhage and shock or to instances in which the disease has been disseminated by ill advised and unsuccessful attempts at removal.

To the third or inoperable group belong patients with tumors, either large or small, that are adherent and fixed and are not movable either with respiration or on palpation. These will probably be found to have broken through their capsule and to have infiltrated neighboring organs so extensively that their complete removal is impossible. The presence of engorged superficial trunk veins may further complicate the clinical picture and indicate obstruction of the vena cava either by pressure of the tumor on the outside of the vessel by glands or from extension into the lumen. In such instances, operation is useless and should not be done.

No more than the essentials of operative technic can be given here. The operation is seldom an easy one, the presence of an inaccessible vascular pedicle together with greatly enlarged veins over the surface of the exposed kidney and possible extension of the growth into the renal vein or vena cava or infiltration of nearby organs presenting difficulties that tax both the ingenuity and hardness of the surgeon and the resistance of the patient. No simple rules can be given for handling them. Each will have to be cared for in a manner dependent on the circumstances under which they are encountered.

The lumbar approach may be used in small tumors in which the entire mass is not larger than that which would be considered readily operable by this route if the enlargement were due to some other cause. In larger growths and in any in which it is probable that prompt and accurate access to the vascular pedicle will be difficult or uncertain, an abdominal transperitoneal approach must be considered. This route has the undoubted advantage of securing the vascular pedicle before there is great need for manipulating the tumor itself. In this way a large part of the blood supply is controlled early and the closing of the main vascular trunks thus accomplished may prevent metastases by squeezing of tumor cells into the blood stream during removal of the tumor itself.¹ Since it has been shown that, in hypernephromas, islands of tumor tissues may be present in it remote from the growth, the perirenal fat should be removed with the tumor. Present practice does not favor removal of the adrenal gland unless it is involved in the growth.

In tumors primary in the pelvis, possible involvement of the ureter must be thought of and a complete or total ureterectomy done if it is found to be involved either before or during operation.²

In children the operation may be technically less difficult than in adults, but both the immediate and the remote mortality are considerably greater. The growths are usually proportionately larger, perhaps because the tumor itself is often the first and only symptom and the disease is not suspected until it is well advanced.

Preoperative irradiation induces fibrotic changes in cortical tumors and makes their removal less difficult.³ Although the method has not been used long enough or on a sufficient number of patients to warrant definite conclusions as to its effects on the end results, reports are favorable and it is probable that the method will have a wide vogue, for the surgeon will quite properly favor anything that will diminish the hazards and difficulties encountered in operating for renal tumor. A disadvantage is that patients may consider that the

growth has been completely destroyed by radiotherapy and thus postpone or refuse surgery. This view should be energetically combated, for, while irradiation may alter the tumor beneficially, it will not destroy it completely.⁴ The irradiation requires three weeks, during which it is conceivable that metastases or extension may occur and this may militate against cure in the long run. Radiotherapy should certainly be used in cases classed as either borderline or inoperable in the hope that removal may be made easier or that otherwise hopeless cases may be brought within the possibility of surgical relief.

Postoperative irradiation to eliminate possible rests that have been overlooked or deliberately left behind seems to be indicated. Just how much should be given and where it should be applied is a problem to be worked out in conjunction with the radiotherapist. Radiation is not innocuous in itself⁵ and to be of value must be administered by a thoroughly competent radiotherapist who has at his command apparatus adequate for the task in hand.

Inoperable cases, apart from indicated hygienic, dietetic and medical measures, should be treated by means of radiotherapy.⁶ The majority of renal tumors are hypernephromas, and, since these are generally radiosensitive, an effort should be made to control metastases and recurrences with the roentgen ray. If used skilfully, they may limit the size of the growths or cause them to shrink and somewhat alleviate a hopeless condition.

POLYCYSTIC KIDNEY

In polycystic kidney the symptoms that attract attention to the disease are due either to hypertension or to uremia from progressive loss of kidney function, to the discovery of an abdominal mass or to some complication, usually infection, hemorrhage or stone. The disease is congenital, bilateral and progressive and accordingly the treatment must be carefully individualized to suit the particular case. It must be emphasized that a polycystic kidney should not be removed simply because of its polycystic condition.

Those patients in whom a palpable mass or nephritic or hypertensive manifestations predominate require symptomatic treatment, which is, as a rule, of a purely medical nature. Surgical treatment is required only if some complication develops, no operation having been devised that will influence the progressive enlargement of the cysts and coincidental loss of renal function more than temporarily. If a surgical procedure is to be undertaken at all, the presence of a sufficient functional reserve in the opposite kidney should be assured more carefully than though the polycystic disease did not exist. The tendency at present is to operate in cases in which previously a strictly conservative attitude has been followed. Surgical renal lesions do not differ greatly in their pathologic nature and pathogenesis here from those occurring in a congenitally normal kidney and their treatment need not be changed materially. Puncture or excision of the cysts may have a beneficial effect on general symptoms, and, in a measure, control pain, infection and hemorrhage.⁷ The fact that the remaining polycystic kidney will not be improved by removal of its diseased fellow but will continue to enlarge and finally fail need not be a hindrance to the removal of the diseased polycystic one.

if it is otherwise affected so as to present a hazard to the life or health of the patient. The complicated polycystic kidney may be removed for the same reasons that a similarly complicated congenitally normal one would be removed, and with the same or more rigorous precautions as to immediate renal insufficiency and death from anuria.

ECHINOCCIC RENAL CYSTS

Renal hydatid disease is rare in North America⁸ and most of the cases reported have been diagnosed as renal or abdominal neoplasms or cysts before operation. Accordingly, any one doing abdominal or renal surgery should be informed as to the general characteristics of the disease in order to be prepared to handle it adequately should it be unexpectedly encountered at operation. In view of their rarity in the United States, information as to their management must be taken from the literature of other countries where the incidence is greater.

The disease is slow in its evolution and unless treated surgically eventually causes death. Apart from an abdominal or lumbar mass and slight hematuria, no symptom may occur unless the cyst breaks into the kidney pelvis, after which scolices and daughter cysts appear in the urine accompanied by moderate hematuria and often by renal colic.

The thick, opalescent wall should enable a fairly accurate differentiation to be made between a hydatid and solitary cyst when it is exposed at operation. Craig and Lee Brown⁹ designate renal hydatids as open if they have broken into and communicate with the renal pelvic system and as closed if this has not occurred, and consider this an important distinction in determining whether conservative surgery is permissible or not. They state that gross infection of the cyst is generally fatal and that for successful treatment it is essential to avoid this accident.

In dealing with closed renal hydatids according to their technic, the cavity of the exposed cyst is opened by as small an incision as is practicable and its fluid contents are aspirated through a trocar, care being taken to prevent soiling the surrounding tissues lest implantation of the scolices or anaphylaxis result. The cyst cavity is then filled with alcohol for five minutes to kill active elements in the germinal membrane, after which the contents are thoroughly evacuated and the abdominal wound is closed accurately about the opening in the cyst, rubber dam drainage being left down to but not into the cyst. They believe that the latter point is important in avoiding infection of the interior of the cyst, which may occur if large tube drainage is employed. Open cysts are treated by nephrectomy.

SOLITARY CYSTS

Large serous cysts are generally unilocular, single and present in only one kidney, they are indefinite as to etiology, uncertain as to diagnosis and favorable as to prognosis.

The simplest treatment consists in trimming off the cyst wall down to the juncture with the kidney substance, destroying the intrarenal lining membrane with phenol (carbolic acid) followed by alcohol and then closing the remaining cavity, either with or without drainage as seems to be indicated by its size.¹⁰ This

procedure is ordinarily simple and easily executed and affords as good a prospect of permanent cure as does either resection of the kidney or enucleation of the cyst itself from the kidney parenchyma by either blunt or sharp dissection. Either of the latter presents the hazard of starting an uncontrollable hemorrhage that may necessitate nephrectomy. By reason of the long continued fistula that it is apt to follow, marsupialization should be used only if adhesions prevent either nephrectomy or excision of the cyst wall and destruction of lining membrane. Nephrectomy in cysts is reserved for instances in which the kidney is largely destroyed either by the cyst or by intercurrent infection or if some other disease, such as tuberculosis or neoplasm,¹¹ is present and requires it.

Since a large proportion of hemorrhagic cysts have been found on painstaking histologic examination to contain carcinoma cells in their walls, the possibility of a neoplasm as a basic cause must be thought of, if the contents of the cyst are hemorrhagic, and the cyst wall carefully examined for it before one decides on a conservative course. If the wall contains thickened areas or if the internal surface is rough after any layers of partially organized clots have been removed, malignancy may be suspected and nephrectomy done unless it can be safely excluded.

TERATOID TUMORS OF THE TESTIS

ARCHIE L. DEAN JR., M.D.
NEW YORK

This paper is a clinical study based on the records of 292 patients with testicular teratomas. It is presented at this time because the increased number of patients permits better evaluation of radiation therapy in this disease and because there have been recent improvements in diagnostic and therapeutic procedures.

PATHOLOGIC ANATOMY

The natural history of the disease must be understood before testicular teratomas can be properly managed. Much is still unknown regarding the origin of these tumors. Ewing's theory probably has widest acceptance. He believes that all teratomas arise from sex cells, most frequently situated in the rete testis but sometimes present in the tunica albuginea. The sex cells are totipotent and for this reason may produce any of the tissues derived from the three primary germ layers. There seems to be a tendency for one type of tissue to outgrow the others, because in most tumors either one tissue predominates or only one tissue is found. After recently reviewing more than 300 microscopic sections of testicular tumors, Ewing stated that he was quite certain that his theory was sound. He said that he was positive of the origin of the common embryonal carcinoma with lymphoid stroma and that in the large group of sections he was able to find every intermediate stage between it and the nonmalignant adult teratomas.

From the clinical standpoint teratomas may be divided into three groups, the adult tumors, intermediate tumors and embryonal tumors. Representatives of

these groups differ considerably in cellular structure and show wide variation in their clinical course and response to treatment

1 Adult teratomas probably comprise less than 10 per cent of all teratomas. In this series they were but 7 per cent of the total number of tumors classified by Ewing. They grow slowly and remain localized. For years they may cause discomfort only on account of their size and weight. Under the microscope, these tumors are found to be composed of adult tissues of one or several types with orderly cell arrangements. Fragments of all organs and tissues have been identified in these growths. Simple orchidectomy is sufficient to cure the patient.

2 The intermediate type of teratoma is partially composed of adult tissues, but it contains malignant embryonal tissue as well. When a complex teratoma gives rise to metastases, the metastatic tumors are nearly always of a uniform composition and consist of the same tissue as the most malignant fraction of the primary growth. Therefore the natural history of these tumors is that of the embryonal portion.

3 The embryonal teratomas are by far the most common type and are noted for their aggressive qualities. They give rise to rapidly growing metastases

TABLE 3—Initial Symptom of 250 Patients

| | Per Cent |
|-----------------------------|----------|
| Painless swelling of testis | 78.0 |
| Swelling with moderate pain | 6.0 |
| Swelling and hardness | 3.2 |
| Hardness | 2.8 |
| Pain in testis | 2.4 |
| Pain and swelling in groin | 2.4 |
| Pain in abdomen | 1.2 |
| Pain in lumbar region | 0.8 |

Certain individuals first noted one of the following symptoms: loss of weight, swelling of leg and thigh, a mass in the abdomen, shrinking of the testis to half the normal size without apparent cause followed by enlargement, the presence of a cordlike growth above the testis.

through both lymphatics and veins. While tumors within this group may be made up of different types of tissue and tumors of the same general type may vary in degree of malignancy, it is rare to find any but the higher grades of malignancy represented.

Observation of many cases has shown that metastatic deposits grow rapidly. Less is known of the rate of growth of the primary tumors. Probably the dense tunica albuginea retards enlargement. Most patients describe a slow but steady growth. Occasionally a tumor reaches a certain size and stops growing for months or years, when enlargement is resumed, usually at a more rapid rate. A slowly growing or quiescent tumor may be traumatized and the rate of growth greatly accelerated. A number of undescended testes, soon after the beginning of enlargement, descended into the scrotum. This was probably caused by the hormone from the anterior lobe of the pituitary gland, because the same result may follow the therapeutic administration of this substance for cryptorchism.

Metastasis occurs relatively early, although there is some variation caused by differences in the structure of the primary tumors. I have seen patients with widespread metastases from tumors no larger than 1 cm in diameter. A number of patients were aware of metastatic tumors before testicular enlargement had been noted. This was more common when the testis was in an abnormal position and could not easily be examined. In most cases lymphatic extension precedes dissemination through veins. The usual route follows lymphatics of the spermatic cord through the pelvic

and lumbar vessels to epigastric nodes and thence up the prevertebral chain through the mediastinum and along with the thoracic duct to the left supraclavicular fossa. Below the level of the epigastric nodes it is rare for metastases to be found on the side of the body opposite the affected testis. Cephalad from the epigastric nodes, metastases from either testis follow the same course. Along this route there are certain regions where metastatic tumors most frequently develop. The most common site for palpable metastases to be found is in the abdomen at the level of the origin of the renal arteries. Epigastric nodes are usually the next invaded, then nodes in the mediastinum and hilus of the lungs, and finally the signal node in the left supraclavicular fossa. Extension along lymphatics is rapid in most cases. By the time a palpable mass is present in the midabdomen it is likely that other, less accessible, regions have been affected. Not infrequently the disease is widespread without any metastases palpable. These facts make it impossible for surgical operations to control the disease.

Metastasis through veins occurred in one third of the patients with metastases. In practically every case they were first demonstrable in the lungs. Excluding the lungs, blood-borne metastases were not found with regularity in any organs, although the brain was invaded next in frequency and in individual cases post mortem examination showed deposits in practically all parts of the body.

The average length of survival of 114 patients who died of teratoma and who had remembered the date of the first symptom was twenty-four months. Since all these men had received treatment, this figure fails to show the actual rapidity with which the disease progresses.

SYMPTOMS

The first symptom in the majority of cases is a painless swelling of the testis, a remarkably insignificant change in the light of possible later developments. Few patients have serious discomfort at first. Those who do usually have undescended testes in which early changes cannot readily be detected. After the first symptom most of the patients notice a gradual but steady enlargement of the testis. In a few cases as have been described, the growth of the tumor is interrupted by a period of quiescence, which may last for months or even years. Most patients notice an early alteration in the consistence of the testis. Usually it feels firm and elastic. It may become quite hard, or differences in density may be felt in different parts. As the tumor increases in size, pain becomes more noticeable. Sometimes the discomfort is in the affected testis, but more often it is described as a dragging sensation in the groin. Since a suspensory gives relief, the distress is probably due to the weight of the tumor. Unless the disease is promptly checked, it may not be long before the patient complains of a dull, aching pain in the lumbar region on the side of the affected testis and notices belching of gas after meals, sometimes associated with loss of appetite and constipation. These symptoms of retroperitoneal involvement occur before the metastasis is palpable. When epigastric nodes are invaded, the symptoms are more striking and are at their worst after eating when the man is likely to vomit. The appetite may not be lost, but, since it is difficult for food to pass onward from the stomach, the body weight and strength decline. Metastases in the chest are usually demonstrable before they cause symptoms. Enlargement of lymph nodes in the medi-

astium or infiltration at the hilus of the lungs may be considerable before symptoms arise. Then the patient may have a sense of fulness beneath the sternum, he may become short of breath, or he may begin to cough. In the same way intravenous metastases in the lung parenchyma may become extensive before symptoms arise. They excite coughing, which later is accompanied by the production of bloody sputum. Hemorrhages into the lungs sometimes occur. Pleural involvement is rare. Metastases in the nodes of the left supraclavicular fossa hardly ever produce symptoms even when they reach great size. Symptoms from brain metastases depend on the area affected. Accurate localization is usually possible.

If metastases spread beyond the ordinary channels, characteristic symptoms may arise, depending on which body functions are affected, but in most of these cases such urgent symptoms are already present that the secondary changes are masked and the full extent of the disease is found only post mortem.

The early symptoms of teratoma, especially testicular enlargement, seem to give the patients concern. Sixty-six per cent of the patients consulted physicians within four months of the first symptom.

DIAGNOSIS

While in most cases the testis is an exposed organ and changes in its size or consistence seem to be readily appreciated by men of average intelligence, teratomas develop so rapidly that by the time the patient first consults a physician metastasis may have occurred. Of thirty-nine patients seen at the Memorial Hospital within three months of the first symptom, 67 per cent had metastases. When it is so essential to make a correct diagnosis without delay, every intrascrotal swelling should be examined with the possibility of teratoma in mind.

The patient is usually a young man who complains of swelling of one testis. After the scrotal contents have been gently palpated in the erect position and varicocele has been ruled out, the patient should be placed in the supine position with the thighs, abdomen, chest and neck uncovered. Inspection shows a unilateral tumor in the scrotum. The average teratoma is about twice the size of a normal testis when the patient first visits his physician. In most cases the skin overlying the tumor is normal. Sometimes if the growth is large the skin is tense and glazed. At the base of the penis there is no swelling as there is with a hydrocele to cause an apparent shortening or retraction of the penis. The abdomen, chest and neck should be carefully observed, because occasionally metastases may be seen, particularly if they are present in the chest wall or in the left supraclavicular fossa.

Only the lightest touch should be used in examining testicular tumors. Palpation usually reveals a smooth, elastic, symmetrically enlarged testis, although stony hard areas may be present or the finger tips may sink into cystic depressions. The shape of a normal testis is maintained because of the dense, inelastic tunica albuginea. The tumor is seldom sensitive. The growth nearly always is limited to the testis, and the epididymis feels normal. Also in most cases there is a clear cut line of demarcation between the testicular tumor and a normal spermatic cord. The records in the present series contain four cases (about one in seventy-five) in which involvement of the spermatic cord was continuous with the growth in the testis. Not infrequently fluid surrounds the tumor. If it is aspirated

without puncturing of the tunica albuginea, no harm is done and the testis can be palpated more easily. Usually the fluid is clear. If it is bloody the growth has probably invaded the epididymis, because all the testis is enclosed within the impermeable tunica albuginea. If pulsation of the spermatic artery can be felt, it is supposed to be evidence of testicular tumor. The tumor does not transmit light.

Metastases are not found in the inguinal lymph nodes unless the scrotum has become involved. Pelvic examination by rectum is usually negative, although in a few cases, mostly late in the disease, a firm rounded mass can be felt somewhat above and lateral to the upper limits of the prostate.

Often the diagnosis is in doubt when based on examination of the testicular tumor alone, especially when a hydrocele has been found or the patient's story suggests an injury, torsion of the spermatic cord, or tuberculosis. If a characteristic metastatic tumor can be discovered, the problem is simplified. Therefore in every case of testicular enlargement the abdomen, chest and supraclavicular fossa should be examined, and when a man has a tumor of the abdomen, chest or left supraclavicular fossa the scrotal contents should be carefully palpated.

Abdominal metastases are found on the same side as the primary tumor and are at the level of, or somewhat caudad to, the umbilicus. When palpable they are single, rounded firm, fixed and not tender. Because they are retroperitoneal, percussion shows that they are overlain with intestine. If the mass is on the left side, a stomach distended by gas will cover the tumor. Metastases in the epigastrium are not easily felt.

Roentgenograms of the chest should be taken as a routine in search of the earliest evidence of intrathoracic metastases. Extensions of the disease through lymphatics cause a widening of the mediastinum or an infiltration of the hilus of the lungs. Intravenous metastases are round dense, sometimes single but usually multiple and are situated in the parenchyma of the lungs. Metastases in the well known signal node in the left supraclavicular fossa may be of almost any size. If they are searched for they are easily found when present and their nature should be readily recognized.

If a patient is examined within a few weeks of orchidectomy, the distal end of the spermatic cord will feel indurated even though it is not the seat of tumor.

The dense tunica albuginea is an important natural barrier to the spread of a teratoma and it should never be incised for the purpose of obtaining a specimen for histologic examination. Whenever this mistake is made the tumor promptly fungates and spreads rapidly. I have found that a biopsy can be safely performed by aspiration through an 18 gage needle if intensive irradiation is given as soon as a positive report has been returned. Since all the steps of an aspiration biopsy can be performed within ten minutes, the patient's safety is not unduly jeopardized. Supraclavicular nodes and other superficial tumors of a suspicious character can also be accurately diagnosed by this method. In addition to the foregoing examinations, the first specimen of urine voided in the morning is referred to the laboratory for the Aschheim-Zondek test.

A minority of the patients in this series were correctly diagnosed at their first examinations. Teratomas were diagnosed as hydrocele, epididymitis, tuberculosis, gumma, hernia, hematoma, and torsion of the spermatic cord. Metastases were thought to be

gallstones or hypernephromas. While incorrect treatment was being given, 195 patients lost an average of six and one-half months before they were referred to the Memorial Hospital. This delay was partially responsible for 73 per cent of the patients having metastases on admission.

THE USE OF THE ASCHHEIM-ZONDEK TEST

Estimation of the amount of follicle-stimulating factor excreted in the urine may be of considerable value in the diagnosis and prognosis of teratoid tumors of the testis. The technic described by Ferguson⁶ must be followed. The usual test for pregnancy is not sufficiently sensitive. Many misunderstandings and serious errors have been caused by this factor having been overlooked. The report should always describe the strength of the reaction in the number of mouse units per liter of urine, because the significance of the test largely depends on quantitative output. Of greater value than a single test are a number of tests performed at intervals. In some instances, to be described later, a series of tests may be required for diagnosis, and in all cases repeated tests are necessary for estimating prognosis.

Like other laboratory tests employed in clinical medicine, the Aschheim-Zondek test is valuable only when correctly interpreted. A clinician using the test in cases of testicular tumors must know its limitations and in each case correlate the laboratory observations with accurate knowledge of the patient's condition.

The reason for the appearance of the follicle-stimulating factor in the urine of men with teratoma is not positively known. Various theories have been presented elsewhere. It is most likely that teratomas produce a hormone which stimulates the basophilic cells of the anterior lobe of the pituitary gland to put out follicle-stimulating factor. Its presence in the urine of a man is abnormal and is an indication for a thorough examination.

For the sake of clearness and brevity the test will be interpreted on the basis of hypothetical cases. Assuming that a man appears for examination with an enlarged testis of a few months duration, that he has received no treatment and that there is no evidence of metastases:

1 If the test is negative it is probable that the patient has no teratoma. It is possible that he has an adult teratoma which has not destroyed the interstitial cells of the testis.

2 If the test shows 500 or less mouse units per liter of urine it is probable that the patient has a teratoma. This may be of an adult type, such as an adult cystic teratoma that has largely or wholly destroyed the interstitial cells of the testis, or it may be a smaller tumor of a low grade of malignancy which has not destroyed the interstitial cells. It is possible that the testis is the seat of syphilis, tuberculosis, interstitial orchitis or any other condition that would cause swelling and complete destruction of the interstitial cells. It should be understood that it is exceptional for a testis affected with syphilis, tuberculosis or interstitial orchitis to have all the function of the interstitial cells destroyed so that a positive test is obtained.

3 If the test shows between 500 and 1,500 mouse units per liter of urine, the tumor is probably a seminoma.

4 An output of between 2,000 and 10,000 mouse units per liter indicates an embryonal carcinoma with lymphoid stroma.

5 An output of more than 10,000 mouse units per liter of urine indicates an embryonal adenocarcinoma or a chorio-epithelioma.

If a man has an untreated tumor of the testis and evidence of metastases, the Aschheim-Zondek test will be positive with probably more than 1,000 mouse units per liter output. In this group also the histologic make-up of the tumors may be indicated by the quantity of follicle-stimulating factor excreted. While in general in untreated cases the output is increased in proportion to the extent of metastases, the increment is less than that caused by a higher grade of malignancy. No condition other than teratoma has been known to present this clinical picture together with a positive Aschheim-Zondek test.

If a patient has been recently castrated for a testicular swelling and there is no evidence of metastasis, a single test is of little value. In these cases, in addition to frequent physical examinations, the test should be repeated every week or two. If histologic examination of the excised testis shows teratoma and the general trend of the tests during several months indicates a constantly diminishing output of the follicle-stimulating factor, the patient was probably cured by operation. If the output of the follicle-stimulating factor steadily increases, it is probable that metastases are present whether or not they are demonstrable by other methods.

If a patient has a testicular tumor without evidence of metastasis and a positive Aschheim-Zondek test has been obtained, it will be discovered in many cases that a short time after the tumor has been given intensive irradiation the test will become negative. This indicates that the tumor was radiosensitive and suggests a favorable prognosis. On the other hand, in those cases in which the test remains practically the same after irradiation as before, the tumor has always been found to be radioresistant and the outcome has been fatal regardless of how intensive the treatment has been. Ferguson has emphasized the invariably bad prognosis of a persistently high output of follicle-stimulating factor after irradiation of the primary tumor. In a number of these cases, prognosis based on histologic examination was relatively good, for the structure of the tumors showed radiosensitivity. The fact that the biologic test proved superior in prognostic value to the histologic examination suggests that other tests may be discovered in the future of greater accuracy than any now known.

There is a large group in which it has been recently learned that the Aschheim-Zondek test is of doubtful value. It is composed of those patients who have had the diseased testis removed surgically or treated intensively with radiation and have been free from evidence of disease for a number of months or years. They may or may not have had metastases when treatment was begun. These men have an irregular output of follicle-stimulating factor, which may vary from zero to 2,000 mouse units per liter within a few days with no demonstrable changes in their physical examinations. The cause of this phenomenon is not known. For some time my associates and I were much disturbed by finding a comparatively high output in a number of patients who had been clinically well for several years. When it became obvious from repeated tests that the reports followed no definite trends and were in no way

6 Ferguson, R. S. *Am J Cancer* 18: 269-294 (June) 1933. Ferguson, R. S., Downes, H. R., Ellis, E. and Nicholson, M. E. *ibid.* 15: 835-843 (April) 1931. Ferguson, R. S. *Pathologic Physiology of Teratoma Testis* J. A. M. A. 101: 1933 1937 (Dec. 16) 1933. *Am J Roentgenol.* 31: 356 (March) 1934.

substantiated by physical observations, it was concluded that in these cases the output of follicle-stimulating factor was dependent on some unknown but late factor of hemicastration. Therefore the Aschheim-Zondek test is not recommended for diagnosis or prognosis later than approximately eight months after irradiation or surgical removal of a testis.

HISTOLOGIC DIAGNOSIS

The histology of teratomas need not be described. It is well known that in the adult tumors various tissues and fragments of organs may be identified and that the embryonal carcinomas are characterized by a highly malignant appearance. There is another microscopic picture, which has not been previously described but which is of great clinical importance. It is seen in radiosensitive tumors after irradiation with such frequency as to make it a pathologic entity. Clinicians and pathologists should recognize the condition, otherwise the patient will lose the benefit of further treatment.

A few irradiated tumors are transformed into a necrotic mass of shadow cells surrounded by a relatively avascular fibrous capsule. The diagnosis of embryonal carcinoma can still be made from the arrangement of the shadow cells, although the individual cells are necrotic. A later stage of this process transforms these necrotic cells into a homogeneous, caseous-looking mass in which no cell outlines can be distinguished and the lesion may be, and in several instances has been mistaken both grossly and microscopically for, a gummatous testis. Later stages of these changes have not been traced, but probably the end result is a relatively avascular cicatrix.

In other tumors, the result of irradiation, in addition to necrosis of tumor cells, is damage to blood vessels, hemorrhage, and conversion of the involved testis into a hematoma. In the end stage the lesion cannot be distinguished from any other hematoma with added radiation changes. Its final organization also has not been traced but there is no reason to believe it different from that of any other hematoma.

A third postirradiation result presents a more complicated picture. One finds the testis transformed into a loose fibrous reticulum, poor in cells. The spaces of the fibrous reticulum represent the former location of strands of tumor cells and more peripherally of testicular tubules, which, in the original lesion, may have been lined by tumor cells. Surrounding each of these spaces left by the disappearance of tumor or testicular parenchyma is a thick, homogeneous, hyaline membrane doubtless in part the remainder of a basement membrane and in part a hyaline thickening of the stroma of the preexisting tumor. An occasional remnant of a hydropic degenerated cell, unidentifiable as to type, may line the hyaline membrane. In the interstices of the spongy, coarse reticulum one finds occasional lymphocytes, probably the remains of the lymphoid stroma possessed by many of these tumors. With time the productive fibrosis increases and results in the obliteration of the spaces, some of which become lined by calcific deposits. Here again the end result seems to be an atrophic hyaline scar tissue poor in blood supply.

TREATMENT

Study of the natural history of the disease shows that the great majority of teratomas are highly malignant and metastasize relatively early. Also, soon after they occur metastases spread with great rapidity to

inaccessible parts of the body. These facts alone should make one hesitate before employing surgery as the treatment of choice. Furthermore, on the basis of end results the recent statistics of Hinman⁷ and the review of Wasterlain⁸ show that there is no justification for either simple orchidectomy or the radical Hinman-Chevassu operation.

Wasterlain concluded that fewer than 6 per cent of the patients were alive four years after simple orchidectomy. This figure corresponds with the incidence of nonmalignant adult teratomas. As to the radical operation, Wasterlain states that in France the four year end results have not justified its original theoretical promise.

Gregoir, who performed the first radical operation, states that twelve of his thirteen patients died between two and twenty-four months following operation. The only survivor is still living after nineteen years, but no metastatic lymph nodes were found in this case. Gregoir concludes that simple castration might have produced the same result.

Hinman gives the only five year end results of radical surgery in the treatment of teratoma testis. He shows that, of 100 patients operated on by American surgeons, seventeen are free from evidence of disease five years after operation.

Five year end results following the use of radiation show its superiority even when a large proportion of the patients had far advanced disease and many were treated by the relatively inefficient early methods.

During the past fifteen years, improvements have been made in the sources of radiation and in the methods by which the agent has been applied. At present we employ the 200 kilovolt roentgen-ray unit and treat patients with the divided dose technic. This method is most efficient in treating deep tumors, so situated in the body that roentgen rays can be directed on them through several different skin portals. Full advantage is taken of the fact that there is a considerable amount of regeneration in the skin and superficial tissues in the time between treatments. When repeated suberythema doses of radiation are given a skin portal with a day or two intervening, a far greater aggregate dose can be given than if a full skin dose were given in a single application. Of course regeneration also takes place in the tumor between treatments, but when a number of portals are used in turn the tumor is irradiated daily while each portal is permitted several days' regeneration between treatments. Therefore the net result of the divided dose technic is a greater total amount of radiation delivered to the tumor with less damage to the overlying tissues.

When there is no evidence of metastases, primary testicular tumors should be irradiated and then removed. Observation of a number of cases in which preoperative irradiation had transformed highly malignant tumors to necrotic debris suggested that, from the theoretical standpoint, it would be advantageous to operate on teratomas after their growth properties had been destroyed. It is impossible to know how frequently operative trauma produces metastases but there is no question as to the cause of the not infrequent local recurrences in the operative wound. In practice, preoperative irradiation has been valuable. We have never had a local recurrence after orchidectomy. Also comparison of the end results when patients were treated otherwise identically shows a difference.

normal mate This shrinkage usually requires from four to six weeks When this stage is reached, orchidectomy is carefully performed The spermatic cord is first crushed and ligated at the subcutaneous inguinal ring, then the tumor with the tunica albuginea intact is gently freed and removed

When measurements show no reduction in the size of a tumor two or three weeks after irradiation, it is removed without further delay In these cases the tumor is either radioresistant or it has been transformed by radiation into a hematoma

The fact that cellular devitalization follows the administration of the amount of radiation which we employ for preoperative use does not mean that the initial regression necessarily is a permanent one Unless supplemented by orchidectomy or additional irradiation, it is possible that the primary regression might be followed by tumor regeneration However, the dose recommended is of such strength that it will cause devitalization of the great majority of teratomas and at the same time leave the overlying tissues in such a condition that they will readily heal after operation¹⁰

With radiation available, the only reason for the operative removal of a radiosensitive teratoma is the preservation of the spermatogenic function of the remaining testis A number of patients have refused orchidectomy and are among those well for more than five years However, they were irradiated repeatedly

9 The following factors are now employed 200 kilovolts with 30 milliamperes of current and filtration of 0.5 mm of copper and 1 mm of aluminum All primary testicular tumors are treated at 50 cm distance all metastases at 70 cm. The skin portals are as large as the size of the patient permits

10 In a group of tumors of different sizes in which microscopic examinations showed that preoperative irradiation had caused complete necrosis computations showed that the amount of radiation received by the portion of the tumor farthest from the source of radiation varied between 0.8 and 1.6 threshold erythema doses The centers of these tumors received between 1.7 and 2.5 threshold erythema doses

because the minimum dosage requirements are not known and in spite of all protective measures the spermatogenic function of the normal testis was destroyed

If, in addition to the primary tumor, a patient has metastases, orchidectomy is seldom performed Treatment of the testis is repeated several times at as short intervals as the skin will tolerate

Whether or not metastases can be found, the pelvic and lumbar lymphatics of the same side as the affected testis and the epigastric region are given full doses of radiation The abdomen is divided into the following six portals (1) lower abdomen anterior, (2) lower abdomen posterior, (3) midabdomen anterior, (4) mid abdomen posterior, (5) epigastrium anterior, (6) epigastrium posterior Two portals are treated daily with a skin dose of 300 roentgens to each until from 2,100 to 3,000 roentgens have been given each portal The two daily exposures are given to different regions, because cross-firing the same region often causes nausea.

When metastases are found in the lungs or mediastinum, enough anterior and posterior portals are mapped out to include all the affected regions Two portals are treated daily with a dose of from 200 to 300 roentgens to each until each portal has received approximately 2,000 roentgens Cross-firing is also to be avoided in treating the chest

The doses of radiation described will cause regressions in the great majority of metastases and will be well tolerated by the average patient However, one must be prepared to change details of the treatment at any time in order to cause the greatest possible regression of the tumor with the least discomfort to the patient

They were referred to the Memorial Hospital before metastases could be found. They were treated by the usual methods of irradiation (table 8).

SUMMARY

A clinical study has been made of 292 patients with testicular teratomas. Compared with all admissions to the Memorial Hospital between 1917 and 1929, teratoma testis comprised 3.39 per cent of all tumors of the genito-urinary system, 2.09 per cent of all malignant tumors in males, and 1.008 per cent of all malignant tumors in both sexes. The patients varied in ages between 1 year and 70. The average age was 31.87 years when the first symptom was noticed and 33.5 years at the time of admission to the hospital. Forty three per cent of the patients were between 25 and 35 years of age at the time of the first symptom, while 80 per cent were less than 40. No occupation seemed to predispose men to the production of teratoma. The marital status had no etiologic significance. No importance could be associated with race, creed or color. The right testis was involved in 52.2 per cent and the left testis in 47.6 per cent, a difference of 4.6 per cent. This difference could be accounted for by the greater frequency of undescended testes on the right side. A frequency of 14.28 per cent of the tumors was noted in undescended testes, which substantiates the belief that misplaced testes are especially liable to malignant changes. Trauma played little if any part in tumor production. No constitutional diseases were found that predisposed to teratomas. Positive signs of pulmonary tuberculosis were demonstrated in fewer than 10 per cent of all patients. Operations for hernia had been performed on 12 per cent before testicular enlargement was noticed.

Ewing's theory regarding the common origin of all teratomas was substantiated by his recent review of sections of 300 tumors. There are three principal clinical groups, adult teratomas, intermediate types and embryonal tumors, the latter making up the great majority.

Primary tumors usually grow steadily and metastasize relatively early through lymphatics and veins.

Metastases grow rapidly and spread widely. The average time of survival of 114 patients who died of teratoma was twenty-four months from the onset of the first symptom.

The initial symptom of 78 per cent of the patients was a painless swelling of one testis. Symptoms caused by metastases are more clear cut and urgent. It is essential to make the correct diagnosis without delay because the disease may spread rapidly. Of thirty-nine patients seen within three months of the first symptom, 67 per cent had metastases. Every patient with a testicular swelling should have a thorough examination of the entire body. The Aschheim-Zondek test, when properly performed and correlated with the physical observations is of considerable diagnostic and prognostic value. The microscopic picture of radio-sensitive teratomas after irradiation is characterized by necrosis, hemorrhage and hyaline degeneration, probably followed by cicatrization.

Treatment of a primary tumor without metastases consists in irradiation followed by surgical removal from four to six weeks later. This devitalizes the tumor before operation and saves the spermatogenic function of the healthy testis. When metastases are present orchidectomy is seldom performed, and irradiation alone is employed in the treatment of both primary and secondary tumors.

In a series of 170 patients with teratomas, 72 per cent of which had metastasized, the five year end results after irradiation show 29 per cent of the men living and free from disease. On the basis of these results it seems reasonable to conclude that irradiation is the best treatment for testicular teratomas in all stages of the disease.

30 East Fortieth Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. LE COMTE AND DEAN

DR. LAWRENCE R. WHARTON, Baltimore. During the last four years I have irradiated the ordinary Grawitz hypernephroma, the cystic carcinoma, Wilms's embryoma (these were all massive tumors and the results have been very good) and, in addition a cortical tumor of the adrenal, a massive tumor in a child 2 years old with sexual precociousness. This result also was good. I agree with Dr. LeComte that irradiation is not a curative procedure and that tumors of any size should be removed transperitoneally. The tumor must be removed without rupture. An incision in the lumbar region naturally gives one the quickest access to the tumor, but unfortunately that does not answer the problem. The crux of the situation is the renal pedicle. There are three things that have been helpful to me in removing kidney tumors. The patient must lie on his back with his back extended as if for a gallbladder operation. That brings the posterior abdominal wall closer to the surface. The anesthetic must be deep enough to give abdominal relaxation. The incision must be so large that one must never feel that one is working in a hole. The peritoneum is opened, the large intestine is pushed back and the posterior abdominal wall is exposed. In taking out a tumor of the kidney I always start the mobilization of the posterior peritoneum some distance from the tumor, mobilizing it freely all the way up along the intestine, which gives complete mobilization of the large intestine and the duodenum and gets them out of the way. It also gives a clear picture of the planes of cleavage around the kidney so that one does not have to approach the kidney or the tumor first. The tissues around it are mobilized. Having cut the peritoneum, one immediately comes down on the retroperitoneal region. This covers the ureter, the spermatic vessels and the kidney pedicle. In order to find the renal vessels clearly, one can pick up the ureter and follow it up or can mobilize the region of the lower pole and slide up along the pole until the pedicle is found. The planes

of cleavage are seen in this operation as they are not in a lumbar nephrectomy. In general, I would never remove the large tumors of the kidney without preoperative irradiation, and if the tumor is as large as a lemon or an orange I would always do the transperitoneal operation.

DR. HENRY SANGREE, Philadelphia. Dr. LeComte has advanced a new clinical classification of kidney tumors: those that are radiosensitive and those that are treated surgically. My anatomic and symptomatic division has been those tumors that are chiefly cortical and those originating in the kidney pelvis. The plea for early diagnosis and early surgical and roentgenologic treatment is of paramount importance, for it is well known that on the degree of malignancy depends proportionately the completeness of cure and the duration of life. Many tumors, especially those containing embryonal constituents that are considered inoperable, are considerably decreased in size because they are radiosensitive and after irradiation become good surgical risks. In a series of fifty kidney tumors, I had a case of Wilms's tumor, considered inoperable, which was markedly decreased in size by receiving roentgen treatment, and then the tumor was removed surgically. The child lived four and one-half years. Two other patients, one receiving surgical treatment and the other roentgen therapy, survived about one year and three years respectively. These results of kidney tumors in children closely correspond with the concept of the speaker, in that the tumor was the first symptom noticed, and the mortality rate, no matter what procedure was used, was much greater than that obtained in adult life. A point to be stressed is that the extensive irradiation of a tumor with the formation of dense scar tissue surrounding it makes a subsequent nephrectomy more difficult and may often outweigh the advantage gained by irradiation. Careful cystoscopic, pyelographic and urographic investigation is of extreme value in a case of hematuria. The triad of symptoms consisting of pain, tumor and hematuria is characteristic of kidney tumors, and in my series one or all appeared in 82 per cent of cases. Pain, however, was the most prominent symptom, and hematuria occurred least often as the chief complaint. Through such educational symposiums as this an increasingly greater number of cases of kidney tumors will be seen much earlier and a careful urologic and roentgenologic examination made, and through the cooperation of the surgeon, roentgenologist and pathologist a greater number of permanent and lasting cures will be effected, for on the size, extent and degree of malignancy depends hope for earlier diagnosis and earlier surgical cure.

DR. GEORGE C. PRATHER, Boston. While it is wise to continue the campaign for earlier diagnosis in all types of malignant conditions, no doubt urologists will continue to be faced with the problem of handling moderately large kidney tumors. Surgical technic in this problem has probably attained most of the accomplishments of which it is immediately capable, especially when the transperitoneal approach is used as recently described by Wharton. Therefore, if one cannot be assured of less advanced cases and if no remarkable improvement in surgical technic is available, other factors that may be of help must be searched for. In patients with no demonstrable metastases, who seem to have a chance of cure even though the local tumor is large, one might be able to be of service who gets the tumor cut without too much surgical shock and without inducing a spread of tumor cells. Preoperative or postoperative irradiation in the past, with a single or a few massive doses, has been extremely disappointing. I believe that the so-called fractional dose method of radiation treatment should be considered and probably used before operation in all tumors of the kidney cortex. While this requires daily roentgen treatment for approximately three weeks and an interval of approximately three weeks between the completion of this treatment and nephrectomy, it does give promise of being of definite value. The reduction in the size of the tumor makes nephrectomy vastly easier for both the patient and the surgeon. This response has been evident in my two cases. There has been no interference with surgery in the nature of fibrous adhesions and no interference with muscle or skin healing. The areas of devitalized cells in the tumor may also reduce the chance of cell dissemination at the time of operation. Dr. LeComte has rightly emphasized the fact that roentgen treatment will not

kill all the tumor cells in the kidney, so that nephrectomy will continue to be necessary. The delay of six weeks before nephrectomy is not a valid objection. It will take time for all of us to collect sufficient observations on cases handled in this way and such reports will be awaited anxiously.

DR. BENJAMIN S. BARRINGER, New York. The tumor described by Dr. Dean is the one tumor of the body, in its more malignant aspects, in the embryonal type, in which external irradiation alone sometimes cures. The Aschheim-Zondek test has been puzzling because of irregular results, particularly after the testicle has been irradiated. I think that it is of great value, much as the Wassermann test is of value in the diagnosis of syphilis, but before irradiation of the testicle has taken place. I had a case in which I was puzzled as to whether the patient had a teratoma or an infectious testicle. The Aschheim-Zondek test showed a high titer of gonadotropic substance in the urine, and I think that it clinched the diagnosis. In these cases it is of value. Just of what value it is in cases in which irradiation has been done cannot be told at present. I think it should always be used as a Wassermann examination is used, as an aid and not as a final judgment in the diagnosis or prognosis.

DR. RALPH M. LECOMTE, Washington, D. C. My experience has not been the same as Dr. Sangree's with regard to preoperative irradiation of the renal neoplasm making operation more difficult. I think that it has made it easier, it controls a good bit of bleeding, the tumor is smaller and more accessible, and matters are very much facilitated. Irradiation will not cure these renal tumors. Since I have been in Atlantic City I have heard of another case in addition to that of Dr. Wharton in which radiation was used some three or four months ago and the pain and hematuria were stopped. The patient then refused operation and has had a relapse of his bleeding for more than a month. He will not be operated on but will follow through with irradiation and die.

IMMUNOTRANSFUSION AND ANTITOXIN THERAPY IN HEMOLYTIC STREPTOCOCCUS INFECTIONS

CHAMP LYONS, M.D.

BOSTON

Hemolytic streptococci produce disease by virtue of two attributes, namely, the ability of the bacteria to invade the body tissues and the capacity to form toxins. These are separate qualities requiring separate antibodies for their effective neutralization within the body. The immunologic evidence to support this conception is now sufficiently complete to warrant the therapeutic use of specific antitoxin and specific antibacterial antibody.

Bacterial invasiveness connotes the ability of an organism to invade the body and there cause local or disseminated abscesses, cellulitis or bacteremia. The capacity to invade is a primary attribute of virulence, because bacteria must be able to live and multiply in order to produce harmful toxins in the body.

The only definitely known method whereby the body can destroy gram-positive bacteria is the process of phagocytosis and intracellular digestion. Ward and Lyons¹ have recently presented a series of studies on the virulence of and the antibacterial antibody for the hemolytic streptococcus of human origin. The forms virulent for man possess distinctive cultural characteristics, develop capsules in young culture, and resist phagocytosis in blood that does not possess the type-specific antibacterial antibody, or opsonin, in the serum. Phago-

From the Surgical Laboratories of the Massachusetts General Hospital and the Department of Bacteriology and Immunology, Harvard Medical School.

cytosis by human leukocytes depends on the presence of this specific opsonizing antibody. Mouse protection is also correlated with its presence.

The hemolytic streptococci are a diverse group with an unknown and presumably large number of immunologically different types. The commercially prepared polyvalent antistreptococcus antiserums² were found not to possess this specific opsonizing antibody for any one of a large number of strains tested. So far it has been possible to produce the essential antibody only by the injection of living streptococci into animals. This obviously renders commercial production impracticable at the present time. It was then observed that healthy adults possessed this particular antibody for one or more strains of hemolytic streptococci. The concentration of the antibody in the serum of such individuals was sufficiently high to permit its transfer to nonimmune bloods in detectable *in vitro* quantity if a dilution of 1:8 (1 part of immune serum and 8 parts of defibrinated blood) was used. This experience suggested that transfusion from donors possessing such an acquired immunity might be a practical clinical procedure.

Although these studies have emphasized the importance of bacterial invasiveness and the antibacterial antibody, there is no attempt to minimize the importance of the toxins in the production of the clinical manifestations of hemolytic streptococcus infections. The best known of these toxins are the erythrogenic, or rash-producing, toxins responsible for cutaneous erythema, persistently high fever and rapid pulse. There are at least two, possibly more, of the erythrogenic toxins, and one strain of streptococcus may produce varying quantities of one or both.³ Scarlet fever antitoxins and erysipelas antitoxins owe such therapeutic efficiency as they possess to their capacity to neutralize the erythrogenic toxins. Parish and Okell⁴ have demonstrated that animals immunized to the toxin and then injected intravenously with a toxin-producing strain of hemolytic streptococcus are protected from an acute toxic death but subsequently succumb to a generalized streptococcal infection. This experimental evidence is supported by the numerous clinical reports that the use of antitoxin in scarlet fever has effectively combated the toxic manifestations but has not materially altered the incidence of the invasive complications such as cervical adenitis, otitis media and bacteremia. It is not yet possible to assess properly the importance of those other toxins produced by the hemolytic streptococcus and recognized in the laboratory as fibrinolysin,⁵ hemolysin and leukocidin.

The foregoing considerations make it possible to consider hemolytic streptococcus infection in terms of septic (bacterial invasion) manifestations and toxic (erythrogenic toxemia) manifestations. This paper is a report on the technic of evaluating antibacterial immunity and the selection of donors with a high degree of acquired type-specific antibacterial immunity for purposes of immunotransfusion. A few illustrative cases are presented and discussed to emphasize the importance of treating these infections in the light of our present immunologic conceptions, that is, to administer antibacterial antibody or antitoxin or both when certain indications are present.

² The antistreptococcus serums examined were obtained from three American and one European biologic products company.

TECHNIC

The phagocytic technic described here has been previously reported.⁶

1 Determination of Antibacterial Antibody in the Blood of Patients—About 8 cc of blood is withdrawn by aseptic venipuncture and defibrinated by shaking in a flask with glass beads, 0.25 cc of blood is measured into a pyrex glass tube 5 cm long and 9 mm wide. One drop (about 0.03 cc) of a young culture of the streptococcus to be studied is added, the tube is sealed in an oxygen flame and rotated for thirty minutes at sixteen revolutions per hour at 37°C. The tube is then flamed and broken open, and one drop of the contents smeared as a blood film. This is stained with Wright's stain and examined with the oil immersion lens. A count is made of the number of intracellular streptococci contained in twenty-five polymorphonuclear leukocytes and the percentage of cells taking part in the phagocytosis is noted. A control slide is usually made from a similar preparation in infant's blood, but this control may be replaced by cultural tests after a little experience.

The bacteria for the phagocytic test are prepared by inoculating one drop of a sixteen-hour broth culture into 4 cc of 50 per cent horse serum neopeptone water^{7a} and incubating until the first clouding occurs—usually from two to four hours. The method of isolating virulent variants has been reported^{7a} and all supposedly pure cultures of such virulent variants are checked repeatedly for failure to show spontaneous agglutination when an eighteen-hour culture in 5 per cent horse serum neopeptone water is mixed with saline solution and heated to 55°C for three hours in a water bath^{7a}.

2 Selection of Donors for Immunotransfusion—The blood serum from each of the prospective donors is centrifugated free from cells. To 0.25 cc of the patient's blood is added one drop of a given donor's serum. Tubes are so prepared for each prospective donor. The bacteria are added as before and the test is repeated. The slide showing the greatest amount of phagocytosis indicates the desired donor.

3 Method of Selecting Antitoxin—In a limited series of cases it has been found that the injection of an erysipelas or scarlet fever antitoxin into the area of erythema accompanying a hemolytic streptococcus infection may produce one of two reactions. There may be a transitory blanching, which disappears as soon as the injection is stopped, or there may be a blanching that persists for from fifteen minutes to two hours. This prolonged blanching has been taken to indicate therapeutic potency, a belief that has been borne out by clinical observation. Antitoxins that do not produce this prolonged blanching have not produced any detectable clinical effect. The presence of toxemia is determined by the clinical observation of erythema, high fever and rapid pulse.

REPORT OF CASES

CASE 1—A. B. C., student nurse, reported off duty because of a painful, throbbing and reddened thumb, which she did not recall having injured. Examination revealed that there was cellulitis of the thumb without appreciable elevation of the temperature or white count. There was an erythema at the base of the thumb without any clearly defined red streaks up the arm. There were, however, definite areas of tenderness along the lymphatic pathways of the arm and it was possible to palpate the thickened lymphatics when grease was applied.

⁶ Ward and Lyons¹ Lyons and Ward¹ Ward H. K., and Enders, J. F. *J. Exper. Med.* 67: 527-547 (April) 1933.

⁷ I am indebted to Prof. Hugh K. Ward, now of Sydney, Australia for advice on the adaptation of the phagocytic technic to clinical usage.

to the skin⁸. There was a small tender axillary node. After twenty-four hours of splinting and hot moist poultices the patient's temperature had risen to 105 F and a subepithelial collection of thin pus was found at the tip of the thumb. This was opened and cultures were taken. Blood cultures were taken and later reported negative. On the morning of the third day in the hospital the entire arm was swollen and tender. The patient's blood was found to contain very little antibacterial

Chart 1—Temperature and pulse in case 1

antibody to the streptococcus from her thumb and that afternoon she was given an immunotransfusion from a donor selected by the method described. Within twelve hours the temperature and pulse rate began to fall, the swelling and tenderness of the arm diminished, anorexia and nausea disappeared and the patient volunteered that there was subjective improvement. After transfusion the blood was again tested and found to have an increased phagocytic efficiency (table 1). On the eleventh day of the disease the axillary node became tender and larger and progressed rapidly to fluctuation. This was drained and the pus yielded a pure culture of hemolytic streptococci. The later convalescence was uneventful. Two months after the patient's discharge her blood was again tested and found to have no antibacterial antibody demonstrable by the phagocytic technic. This would appear to be an instance of passive immunization in the strictest sense of the term. The antibody values of the blood are recorded in table 1.

TABLE 1—Antibody Values of Blood in Case 1

| Day of Disease | Phagocytosis* |
|----------------------------|---------------|
| Third (before transfusion) | 50-28% |
| Fourth (after transfusion) | 100-84% |
| Eleventh | 104-60% |
| Two months later | 6-8% |

* There is no absolute index or maximal value that can be used as a standard to measure the antibacterial antibody. All observations are to some degree relative to previous observations except in those instances in which there is no phagocytic effect. In this and subsequent tables the observed phagocytic values are recorded as 50-28 per cent to state that fifty streptococci were phagocytized by 28 per cent of twenty-five polymorphonuclear leukocytes counted in series.

This case was diagnosed as subepithelial abscess and cellulitis of the thumb, lymphangitis, and axillary adenitis without toxemia. It has not been determined whether the absence of toxemia was attributable to an acquired immunity of the patient or a lack of toxinogenicity on the part of the streptococcus.

Certain very definite conclusions may be drawn from this case.

1 Lymphangitis may exist in the absence of "red streaks."

8 It is my belief that the diagnosis of lymphangitis may be made in the absence of the familiar "red streaks" by the demonstration of tenderness along lymphatic pathways and induration of the lymphatics. This lymphatic and perilymphatic thickening is more easily appreciated if grease is applied to the skin to reduce tactile friction. The erythema of the red streak is blanched when specific antitoxin is injected.

2 Antibacterial immunity may be passively transferred by immunotransfusion with apparent clinical benefit.

3 Hemolytic streptococci may survive and produce suppuration in lymph nodes even in the presence of a presumably effective blood stream immunity.

CASE 2—Z. McB., a farmer, aged 43, had a plastic operation on the tendons of his hand two years after his original infection. On the sixth postoperative day there was an increase in the local induration and a few stitches were removed. On the seventh day there were red streaks up the arm without axillary tenderness. More stitches were removed and hot moist poultices were applied to the arm. On the evening of the eighth day

TABLE 2—Antibody Values of Blood in Case 2

| Time of Test | Phagocytosis |
|--------------------|--------------|
| Onset of infection | 56-32% |
| After recovery | 207-60% |

* See footnote of table 1.

the patient developed a typical scarlatiniform rash over his entire body. The lymphatic pathways of the arm were tender and indurated and there was a visible streak of cutaneous erythema. The erythematous skin was injected with normal horse serum and erysipelas antitoxin but only the latter produced persistent blanching. The patient's blood was found to be actively phagocytic for the hemolytic streptococcus obtained in pure culture from the operative wound. Blood cultures were taken and subsequently reported negative. High fever, rapid pulse and cutaneous erythema persisted. This case was interpreted as one of local wound sepsis with toxemia in the presence of a relatively high blood stream immunity to the bacteria. The deficient antibody to be supplied was clearly the antitoxin. This was done, with immediate fall in temperature and pulse rate and blanching of the rash.

The case is presented to illustrate two apparent facts:

1 Lymphangitis may exist in the presence of demonstrable antibacterial antibodies in the blood stream.

Chart 2—Clinical course in case 2

2 Toxemia may occur in the presence of demonstrable antibacterial antibodies in the blood serum, and it is in these cases that antitoxin alone produces clinically striking results.

CASE 3—R. Z., a woman aged 27, had a plastic operation performed on her hip. A persistent sinus developed in the operative scar. This subsequently became infected with hemolytic streptococci and the patient developed a rapidly spreading erysipelas of the lower half of the body. The blood contained

little antibacterial antibody and the presence of the rash of erysipelas indicated a lack of antitoxin immunity. An erysipelas antitoxin was selected on the basis of the blanching test and given intravenously. This blanching the rash, reduced the pulse rate, and changed the temperature curve from one of persistent elevation to one of the "picket fence" type. It was impossible to find a donor with an acquired immunity to this streptococcus and it was necessary to depend on local treatment of the

Chart 3—Clinical course in case 3

wound. This case illustrates the persistence of infection following the control of the toxemic manifestations alone. After recovery the patient's blood was found to contain antibacterial antibody (table 2).

This case illustrates two observations:

- 1. Antitoxin controls only the toxemic manifestations of the infection.
- 2. Recovery is correlated with the appearance of antibacterial antibody if it has not been previously supplied by immunotransfusion.

TABLE 3—Phagocytic Values of Eight Patients Before and After Immunotransfusion

| Patient | Lesion | Phagocytosis* | |
|---------|-----------------------------|--------------------|-------------------|
| | | Before Transfusion | After Transfusion |
| Ber | Pneumonia and empyema | 64-82% | 800-90% |
| Cad | Cellulitis and lymphangitis | 50-28% | 100-84% |
| Cen | Chronic phlegdenic ulcer | 50-38% | 275-92% |
| Cos | Postbacteremic abscess | 103-44% | 147-84% |
| Goo | Postbacteremic abscess | 263-84% | 808-100% |
| Had | Bacteremia | 14-16% | 120-50% |
| One | Bacteremia | 30-28% | 9-52% |
| Ria | Bacteremia | 4-4% | 202-96% |

* See footnote of table 1

Table 3 presents the observed phagocytic values of the blood of eight patients before and after immunotransfusion. There are as yet no quantitative standards to establish what constitutes a protective level of immunity, but in every case there has been an increase in the phagocytic activity of the patient's blood after transfusion. The clinical application of this method of passive antibacterial immunization is readily apparent.

COMMENT

An attempt has been made to differentiate between the septic (invasive) and toxic components of the clinical picture observed in hemolytic streptococcus infections. Clinical records have been presented to illustrate the manner in which specific cases may be evaluated.

1. *Septic Element of the Infection*—Under this heading are grouped the signs and symptom complex resulting from bacterial proliferation and dissemination within the body.

- 1. Local cellulitis or abscess
- 2. Lymphangitis
- 3. Lymph node inflammation and suppuration
- 4. Swinging "picket fence" temperature.
- 5. Chills
- 6. Positive blood culture.

It has been previously reported¹ that the hemolytic streptococcus owes its invasiveness to its capacity to resist phagocytosis and that the essential type-specific antibacterial antibody is an opsonin capable of inciting specific phagocytosis. Recovery from infection has been correlated with the appearance of this antibody. A method has been described which permits the determination of a patient's serum opsonin content and the selection of a donor with a high degree of specific acquired antibacterial immunity. These tests require about four hours after the streptococcus has once been isolated in pure culture. It is proposed to use immunotransfusion to increase the bactericidal power of the body at the time of infection.

2. *Toxemic Element of the Infection*—The toxemia of the early infection is characterized by signs and symptoms that are attributable to the dissemination of the erythrogenic toxin.

- 1. Cutaneous erythema
- 2. Sustained elevation of the temperature
- 3. Persistently rapid pulse.

Therapeutically potent antitoxins for most cases may be selected by the Schultz-Charlton test of specific blanching. It is to be emphasized that antitoxin should be expected to be effective only in blanching the rash and lowering the temperature and pulse rate.

3. *General Considerations of Immune Serum Therapy*—The clinical course of early, rapidly progressing hemolytic streptococcus infection appears to have been favorably modified by the use of antitoxin for toxemia and immunotransfusion for the passive transfer of antibacterial immunity when necessary.

The evaluation of the antibacterial immunity of infected patients and the experience with immunotransfusions has disclosed one fact very clearly. Hemolytic streptococci may persist in local lesions and in lymphatic pathways even though the blood serum contains a high concentration of antibacterial antibody. Immunotransfusion has been found to clear the blood stream of patients with bacteremia for varying periods of time but it has not prevented the later development of abscesses, particularly in the afferent lymphatic channels. Antibacterial therapy appears to halt the general spread of the invading organism and in its perfected form may simplify the problem of streptococcus invasion by making it primarily one of the management of localized areas of infection.

CONCLUSIONS

- 1. Hemolytic streptococcus infections are of three clinical types: septic, toxemic, or both septic and toxemic.
- 2. The septic manifestations of the rapidly progressive infection are best combated by transfusion from donors having a high specific antibacterial immunity.
- 3. The toxemic manifestations are best combated by antitoxin plus antibacterial antibody.

THE PREVALENCE OF MILD BRUCELLA ABORTUS INFECTIONS

REPORT OF A CASE

W BEECHER SCOVILLE, MD

NEW YORK

In the last few years the profession has become increasingly conscious of the prevalence of undulant fever. But I do not think it has yet realized how common the subclinical and ambulatory forms may be. I hazard the opinion that many such cases may masquerade under the guise of infectious arthritis, nervous exhaustion, undiscoverable focal infection, and chronic neutropenia.

PREVALENCE

Until recent years the specific agglutination tests have been considered the *sine qua non* for the presence of brucella infection. It is now known that negative agglutinins may be of little significance. From 5 to 16 per cent of the cases proved by cultures, skin tests and animal inoculation give negative agglutinins, and a low titer must be seriously considered in the diagnosis.¹ In addition, an astonishingly large number of persons give positive agglutinations with or without clinical symptoms. In 25 per cent of 1,000 routine Wassermann tests, low titer agglutinins for undulant fever were found and 0.3 per cent yielded a titer above 1:40.² Twenty per cent of the cattle in the United States are infected with *Brucella abortus*, and 40 per cent of these excrete organisms in their milk.³ In 100 tests of epileptic patients drinking infected milk, 41 per cent yielded agglutinations of 1:10 or over and 45 per cent gave positive skin tests.⁴ A careful checking of the physical examinations and temperatures showed that 22 per cent were mild ambulatory cases. In Alice Evans's⁵ famous case lasting six years there were months of disability without a rise in temperature above 99.5 F and other months of normal temperature.

Furthermore, the *Brucella suis* type can account for an epidemic from cow's milk,⁶ and there are different strains of *Brucella abortus* varying in virulence, some of which are not even pathogenic for man.⁷ Therefore, except for *suis* and certain virulent *abortus* strains, milk-borne *Brucella* infections are common but may be very mild or run a subclinical course, and in only a few cases are they typical of what one commonly calls undulant fever.

CLINICAL COURSE

Giordano⁸ analyzed thirty-five cases. The chief symptoms were fatigue, anorexia, low fever, headache,

muscular weakness and joint pains. The onset followed an infection of the upper respiratory tract or bronchitis. The course may be for weeks or years. The fever was not undulant but generally septic with remissions, occipital or cervical headaches were common. Back ache and arthralgia of the small joints without redness or swelling were often the only symptoms of the disease. Eye aches, asthenia, irritability, depression and insomnia were common, constipation and gallbladder pains were frequent. The spleen is only rarely enlarged in the *abortus* type. The blood showed a leukopenia and a relative neutropenia. Simpson⁹ summarizes ninety cases. The average duration was four months. Five per cent gave negative agglutinins. (He used animal inoculation, agglutination and skin tests for diagnosis.) The onset was insidious with an afternoon temperature, headache, and muscle and joint pains. Eighty-nine per cent had only one febrile attack early in the disease. Asthenia was the commonest symptom, the spleen was palpable in a third of the cases. Harris¹⁰ has just studied, with many interesting observations, fifty-one cases occurring in general practice in a rural New York district. The majority of the cases were ambulatory, of long duration, and remissive in type. The fever was low grade, muscle and joint pains were the chief complaint, often suggesting a neurosis, there was a striking pallor without secondary anemia, he observed a leukopenia, a neutropenia and frequent alveolar abscesses.

DIAGNOSIS

Complement fixation tests run parallel to the agglutinations.¹¹ Blood cultures, requiring special mediums, are generally negative in the *abortus* type.⁵ There is much dispute as to the value of low titers in the agglutination tests, 1:50 or 1:100 is considered diagnostic in most state laboratories,¹² but low titers of 1:10 or over are now being stressed in the diagnosis of the ambulatory cases.¹³ The skin test should be a routine diagnostic procedure in all cases showing negative agglutinins. There are three types: the broth filtrate form has been dispensed with because of the possibility of a pseudopositive reaction,¹⁴ a saline suspension of the killed organism gives accurate results but may cause a severe reaction and is always followed by a positive agglutination test thereafter.¹⁵ Nucleoprotein fractions in saline, or fat-free alcohol extracts, of the *brucella* organism are now used by the majority, they probably give a much less general reaction, with equal specificity, and cause positive agglutinins thereafter in only 9 per cent of those tested.¹⁶ The

opsonocytaphagic test, as developed by Huddleson, is interesting in determining whether the patient is susceptible, is infected or has recovered. It is an index of the specific phagocytic power of the patient's polymorphonuclears for the brucella organism and the results are clear cut.¹⁷

TREATMENT

Good hygiene, as in tuberculosis, with rest, ultraviolet radiation and a high caloric-vitamin diet, continues the accepted treatment by those inclined to conservatism. "Brucellin," a culture filtrate developed by Huddleson, and *Brucella abortus* vaccine are coming more and more into favor. They are given subcutaneously in increasing doses at three day intervals starting with a minimal dose, with the expectancy of a generalized fever reaction. Excellent results have been obtained in early, and less frequently in chronic, cases.¹⁸ Foreign protein injections are of questionable value.⁹ Pyronine, thionin, mercurochrome and neosphenamine have their lone advocates.¹⁹ To date horse serum sensitized by a culture filtrate has not been successful.²⁰

REPORT OF CASE

I cite my own case of a mild ambulatory form of *Brucella abortus* infection without fever and with negative specific agglutinins. It is interesting to note the absence of those symptoms considered diagnostic of undulant fever. An extremely thorough work-up ruled out alternative organic diagnoses, but at various times it was diagnosed a psychoneurosis, undiscoverable focus of infection, and chronic neutropenic state.

A physician, aged 28, in the summer of 1934, after drinking raw cows milk and eating goat cheese in Norway, developed periodic exacerbations of malaise, easy fatigability and generalized muscle and joint pains. The onset was insidious, following heavy exercise and an infection of the upper respiratory tract. These exacerbations lasted from four to five days and continued for six months. At first they were almost constant, but gradually increasing periods of well being intervened. Fever was consistently absent, with 97 forenoon and 98.6 afternoon temperature readings. The physical examination was negative but weight loss, constipation and marked pallor without secondary anemia were present. For six months good hygiene with rest, ultraviolet rays and a high caloric-vitamin diet was practiced. After this the patient commenced work again in New York and was without symptoms except when overfatigued. If this condition occurred, an exacerbation followed, consisting chiefly of muscle and joint arthralgias, especially wherever a previously strained joint existed, but without local redness or swelling. These attacks at present are becoming increasingly infrequent.

Exhaustive clinical, laboratory and roentgen studies were made. The past medical history was negative, including the sinuses, teeth and the respiratory gastro-intestinal and genitourinary systems, there was no history of rheumatic fever or arthritis, sinus teeth and chest roentgenograms were negative. Examination of the eyes, nose and throat was negative (the tonsils and adenoids being out), gallbladder and gastro-intestinal series, prostatic smear, urine, and throat culture were normal. Blood showed normal erythrocytes and hemoglobin but a constant neutropenia at first running 39 per cent neutrophils of

5,200 leukocytes, and slowly improving to 50 per cent neutrophils of 6,500 leukocytes. The smear was normal. The blood sedimentation rate averaged 5 mm in the first hour and 13 mm. in the second hour. The basal metabolic rate was -15. Blood cultures and serum agglutinations were negative for typhoid, paratyphoid and undulant fever. At the end of five months a skin test according to Giordano's technic using 0.1 cc. of *Brucella abortus* antigen of a saline killed suspension was given intradermally at the University Hospital, Philadelphia. Within forty-eight hours there followed a very marked local and general reaction with a fever of 101 F, malaise, arthralgia, slight lymphangitis, and locally a wheal measuring 2 inches by 1 inch, raised and red. This progressed into a sterile abscess which necessitated incision and drainage three weeks later. The vaccine was rechecked for sterility and a culture of the abscess was taken and found to be sterile except for a nonpathogenic diphtheroid organism. For the duration of the abscess the previous symptoms were duplicated in an intensified form with an afternoon rise in temperature of from 1 to 2 degrees and following incision and drainage a complete cessation of all symptoms for one week. Three weeks after this Huddleson's opsonocytaphagic test was done by Dr. Welch of the Connecticut State Laboratories with the finding of 100 per cent posi-

Appearance of sterile abscess on inner aspect of forearm three weeks after a diagnostic skin test.

tive phagocytosis, indicating high resistance to the *Brucella* organism. (The importance of this test is lessened because of the previous abscess formation with possible sensitization.) It is interesting to note that at this time the blood gave a slightly positive heterophil test for infectious mononucleosis, as is frequently found in undulant fever cases.²¹

COMMENT

Here was a case of mild ambulatory *Brucella* infection with normal or nearly normal temperature and negative agglutination titers, but markedly positive skin and phagocytic tests, with enough subjective symptoms to cause incapacitation, yet with little enough objective signs to cause a diagnosis to be made of neurasthenia, chronic neutropenia, and undiscoverable focal infection. This paper suggests one more substitute for that diagnostic wastebasket "neurasthenia and abortus contributing to the etiology of obscure arthritic conditions." It invites conjecture as to *Brucella* suspected cases of *Brucella* infection showing negative specific agglutinins.

SUMMARY

Mild ambulatory cases of *Brucella abortus* infection are common. Because of the lack of objective signs and the presence of malaise, asthenia, and muscle and joint pains, they are often included in the category of neurotic, arthritic or cryptogenic infections. Laboratory diagnosis should include skin and possible phagocytic tests as well as agglutinations and cultures. The case cited clinically resembled a mild *Brucella abortus* infection. Exhaustive search failed to reveal any focus of infection. The fever and agglutinations were negative, but the skin and phagocytic tests were markedly positive.

525 East Sixty-Eighth Street.

OUTBREAK OF UNDULANT FEVER DUE TO BRUCELLA SUIIS

BENJAMIN G. HORNING, M.D.

HARTFORD, CONN.

An outbreak of undulant fever occurred in an institution maintained for elderly persons in Connecticut during 1934-1935. There were fourteen clinical cases with three deaths. Blood cultures from two of the fatal cases were positive for *Brucella suis*. This organism was also isolated in pure culture from an abscess in the soft tissue overlying the sternum of a third patient. Epidemiologic, clinical and laboratory evidence supports the view that most of the *Brucella* infection of man in this section is due to the bovine strain¹. This was the first outbreak reported in Connecticut due to the porcine organism.

The population of the institution consisted of 305 inmates and eighty-one employees. The case of a 13 year old boy was included because he used milk from

the dairy herd maintained by the institution. Table 1 gives the population by age group and sex, table 2 gives data pertaining to each individual case.

Table 3 analyzes the population, cases and case rate by age groups. Table 4 compares the percentage of population and cases under 50 years and over 50 years in the institution and in Connecticut as a whole.

The age distribution of the patients ranged from 13 to 82 years. Approximately 64 per cent of the patients were over 50 years of age. A study of 202 cases of undulant fever in this state shows that only

18 per cent of the patients were over 50 years of age. This apparent difference is explained by the fact that 79 per cent of the institution's population were over 50 years of age, while it is estimated that only about 20 per cent of the population in the state as a whole are over 50 years of age. The attack rate for the total population of the institution was 3.63 per hundred. The attack rate for males was 3.9 and for females 3.4. The outbreak was too small for an analysis to be of statistical significance.

The symptomatology of the cases did not differ from observations recorded elsewhere for this disease. The onset was usually gradual and could not be determined with accuracy. In several cases one or more months elapsed after the last exposure to the source of infection before symptoms were noted. When questioned, the patient would often say that he had tired easily and had lacked strength for some time. Usually the onset was dated from the day of the first chill. Frequently, an early symptom was moderately severe headache, which might be either frontal or occipital. The temperature curve in all cases was of the undulating type. The maximum elevation of temperature usually occurred after 4 p. m. and was followed by a drop of from 2 to 3 degrees, with the maximum remission after 4 a. m. The outstanding symptoms were ease of fatigue, loss of strength, headache, fever, chills and perspiration. Four of the patients had symptoms referable to the upper respiratory tract early in their illness, and eight complained of mild gastric distress. The duration of the illness is given as from the time of onset until the day discharged from the hospital or date of death. It varied from four to forty weeks. Eleven of the patients recovered, three died.

Complications have occurred in only one case thus far, of a woman, aged 25. The onset was in April, and during June phlebitis of the left lower extremity developed. Later there was an abscess in the soft tissue overlying the sternum, which was excised. *Brucella suis* was isolated in pure culture from the abscess. Two elderly patients had chronic arthritis, these symptoms remained about the same during their illness.

Subclinical brucella infection frequently occurs. It had been hoped that blood could be secured from all the inmates in order to obtain some index as to the amount of subclinical infection. This was not possible. Blood was obtained from forty persons without symptoms. Fourteen, or 35 per cent, agglutinated Huddleson's antigen in low dilutions.

Case 4 was instructive. The onset of symptoms was early in August. A clinical diagnosis of undulant fever was made on August 7. Specimens of blood examined on August 7 and August 14 failed to agglutinate Huddleson's antigen. A specimen on August 21 partially agglutinated the antigen through dilutions of 1:200. A specimen on August 29 agglutinated the antigen through dilutions of 1:6,000. The patient had clinical symptoms of undulant fever for at least three weeks before evidence of the disease could be detected serologically. This case emphasizes the importance of repeated laboratory examinations in the presence of suggestive symptoms.

Epidemiologic investigation revealed two possible sources of infection. The institution maintained its own dairy herd and the milk was consumed raw. All the patients had been exposed to the milk as a food. The institution also kept swine. The hogs were butchered every two weeks during the winter, from November 1

2 Connecticut State Department of Health. Unpublished data.

to March 1. The pork was not kept in cold storage, as only enough was butchered each time to supply meat for two meals.

None of the patients had been near the swine and they had had no contact with the uncooked pork. Thirteen of the patients had eaten the cooked pork, one had not. Careful inquiry revealed the fact that all meat, especially pork, at this institution is thoroughly cooked. No evidence could be found to indicate that the disease had been contracted through contact with the swine or pork.

In the first case the onset apparently occurred in April 1934. It was diagnosed and reported on June 30, 1934. An immediate investigation was made by the state department of health. Raw milk from the institution herd was the only source of infection found. Following the usual procedure, information obtained was given to the state dairy and food commissioner.

The herd belonging to the institution consisted of thirty-six cows and one bull. Blood specimens from the entire herd were drawn under the direction of the state commission of domestic animals and examined at the Storrs Experiment Station. The blood from two of the cows was positive for brucella infection and the blood from a third was suggestive. The positive cows had been in the herd thirty and fourteen months, the third cow had been with the herd fourteen months. Pasteurization of the milk was begun Aug. 1, 1935. Unfortunately, the infected cows were disposed of before the milk could be examined for *Brucella* organisms.

It is unusual in Connecticut to have more than one case of undulant fever on a milk route. Early in this

outbreak *Brucella suis* was suspected as the etiologic agent, first because of multiple cases, and secondly because of the severity of the clinical symptoms. This suspicion was verified by the recovery of *Brucella suis* from the blood stream of two of the patients and from an abscess in the soft tissue overlying the sternum in another patient. As stated previously, the pork was thoroughly cooked, there had been no contact with the swine and one patient had never eaten the pork. Also,

no hogs had been butchered later than March 1, 1934, and these cases all apparently had their onset of symptoms after April 1, 1934.

Considerable evidence has accumulated to show that cattle may become infected with *Brucella suis*, both experimentally and in nature.³ Epidemiologic evidence suggested that this outbreak was due to drinking raw

TABLE 4—Population and Patients Under and Over 50 Years

| | Institution | | Connecticut | |
|----------------|------------------------|-------------------|------------------------|-------------------|
| | Per Cent Population | Per Cent Cases | Per Cent Population | Per Cent Cases |
| Under 50 years | 20.98 | 85.71 | 80 | 81.68 |
| Over 50 years | 79.02 | 64.29 | 20 | 18.32 |

milk from cattle infected with the swine variety of *Brucella*. The hogs' pens at this institution were located near the dairy barns. On their way to pasture the cows loitered around the pens and ate grass. It is possible that this was the method of infection. On the other hand, one of the cows might have been infected before joining the herd. Blood was drawn from thirty-two of the swine. Nine were positive, seven suggestive and sixteen negative for *Brucella* infection. The strain was not identified from the swine. It is assumed, however, that it was *Brucella suis*, as *Brucella abortus* has not been reported as occurring in swine.

SUMMARY

1. An outbreak of undulant fever with fourteen cases and three deaths occurred in a home for elderly persons.

2. Raw milk from the institution herd was the only source of infection found.

3. The herd consisted of thirty-six cows and one bull. The blood from two cows was positive and from another suggestive for *Brucella* infection.

4. *Brucella suis* was isolated from the blood of two patients and from an abscess of a third patient.

5. Blood was drawn from thirty-two swine kept by the institution. Nine were positive and seven suggestive for *Brucella* infection.

6. The cattle had opportunity for natural infection from the swine.

7. Epidemiologic evidence suggests that the outbreak was due to *Brucella suis* received from drinking raw milk from cows infected with *Brucella suis* from swine.

FOOD POISONING FROM ICE CREAM
ON SHIPS

J C GEIGER, MD

A B CROWLEY

AND

J P GRAY, MD

SAN FRANCISCO

The heterogeneous factors usually involved in outbreaks of "food poisoning," more especially the vehicular food, the numbers of persons affected, the delayed reporting of the incident to the health authorities and, particularly, the causative bacteria responsible, constitute a problem that too frequently does not lend itself to easy solution. Much of the information obtained has to be discarded since it is irrelevant to the solution of the problem by accepted epidemiologic technique. As an added complication the problem is not infrequently confused by the lack of agreement between data obtained by direct epidemiologic methods and data obtained by bacteriologic study, or specimens of the incriminated food and of feces and urine from the affected individuals even may not be available for bacteriologic investigation.

Ice cream, as a possible and potential vehicle for the causative factor in food poisoning, offers particular difficulty since there is no uniformity or standardization of procedures and practices. In some instances for example, the mix is heated to the boiling temperature, while in others pasteurization temperatures may be used and the time interval may be left to the judgment of the operator with the result that this factor has wide variability. In other instances the freezing process is applied without any attempt at minimizing the bacterial growth by the application of heat to the mix beforehand. It is a recognized public health fact that ice cream mixtures containing milk, which in itself may show a high bacterial colony count and which may be contaminated through possible mishandling and human contact, nuts and fruits, the whole being mixed in utensils not adequately cleaned or sterilized, offers ample and rich opportunities to enhance bacterial metabolism to the end that the ingestion of the product may cause food poisoning, and the probability of this ultimate conclusion from such a series of events is markedly increased if the mixtures are allowed to stand, even for short periods of time, at room temperatures.

The occurrence of at least four outbreaks of food poisoning, epidemiologically traceable to ice cream containing nuts, occurring aboard an ocean liner sailing from the port of San Francisco, led to an investigation of the circumstances surrounding the manufacture, storage, handling and serving of ice cream aboard the vessel. A brief report covering the outbreaks and their background and of the study made subsequently may be of interest.

In the first of the four outbreaks referred to, fifteen passengers and an indeterminate number of the members of the crew were affected Jan 8, 1935. The illness, in which the symptoms and signs presented included nausea, vomiting, abdominal distress (cramps), diarrhea and in some instances numbness of the extremities, had an incubation period of from three to eight hours and the duration was usually less than twenty-four hours. The food common to all those affected was chestnut ice cream, made aboard ship of

milk, cream, eggs and canned chestnuts in syrup. Samples of ice cream and chestnuts were not available for laboratory study at the end of the voyage, but examinations were made of milk, cream and water. The laboratory reported bacteria colony counts per cubic centimeter for the various specimens: milk, 23,000, cream, 210,000, water, 45, at 37 C and 65, at room temperature with *B. coli* absent in all tubes.

An inspection of the ship's galley, made on arrival in San Francisco, resulted in the correction of a few irregularities in food-handling practice, but no irregular circumstance detected was of sufficient magnitude to account for the occurrence of food poisoning. In the conduct of the study, the examination of the silver polish used, for cyanide, and of the insecticides used, as for fluorides, were unproductive of relevant information.

In the other outbreaks, on April 4 or 5, 7 and 17, thirty-eight people were affected, under circumstances very similar to those described in the first outbreak, with the common food factor in hazelnut ice cream. After the second outbreak of April 4 or 5, definite orders were given that the nut-containing ice cream must not be served, but these orders were not obeyed, and hazelnut ice cream was again served on two occasions, April 7 and 17, with approximately thirty people affected. Laboratory studies were made on specimens of hazelnut ice cream obtained at the end of the voyage from the ship surgeon and directly from the hardening room. All three specimens showed bacteria colony counts in excess of 5,000,000 per cubic centimeter of the original material, with profuse growth of a non-hemolytic staphylococcus (*aureus*) and not a few colonies of the coli-aerogenes group, but in no instance was there evidence of the presence of members of the paratyphosus group of organisms and likewise, no evidence of chemical poisons. Specimens of excreta from the individuals affected were not available for bacteriologic study.

On the basis of these incidents it was believed advisable to place a trained observer aboard the ship so that observations might be carried out under the conditions actually existing during the voyage. The observations made and the information obtained from various sources, including members of the crew, revealed the facts that the utensils used in the manufacture of ice cream were not properly cleaned and sterilized and that ample opportunity was afforded for contamination of the ice cream before, during and after freezing and during the holding of the finished product. It was found that preparation of the mix and its freezing were carried on in the galley itself rather than in a separate room equipped for the purpose, with the result that other employees had contact with the utensils and the food product. Not infrequently employees were found to have the habit of dipping their fingers into the mix, thereby tasting and contaminating the product. On one occasion during the voyage, ice cream was prepared in the freezer before the latter was even washed or cleaned (not to mention sterilization), following the previous freezing, all on account of a lack of fixation of responsibility for cleaning and sterilization of the freezer and other ice cream manufacturing equipment. In fact, no steam hose connections were available for proper cleaning and sterilization of equipment.

An investigation of the quality of the ingredients used and of the conditions under which they were stored revealed some interesting possibilities also, for example, nuts were stored in a room in which the dry

bulb temperature frequently reached the level of 98 F and in which the mean temperature approximated 80 F throughout the voyage. In spite of the fact that relatively high prices were being paid, examination showed that the stock on hand was of inferior grade.

The laboratory studies offer confirmatory evidence of the importance of these circumstances. Two specimens of the hazelnut ice cream made aboard ship, one submitted through the ship surgeon, the other obtained by an inspector at the end of the voyage, showed excessively high bacteria colony counts (54 and 51 million per cubic centimeter respectively) with *Staphylococcus aureus* the predominant organism (about 50 per cent). Cultures for *B. typhosus*, *B. paratyphosus* (alpha and beta) and *B. dysenteriae* were negative in both instances. The specimens of shoreside ice cream (shipped at the beginning of the trip) taken during the voyage, when the observer-inspector was aboard, showed lower bacteria colony counts, sample from hardening room (four days at sea), 3,500 colonies per cubic centimeter, sample after portions had been served from the supply, in the galley, 2,100 colonies per cubic centimeter, sample taken on return to San Francisco (originally shipped aboard at the beginning of the trip), 2,400 colonies per cubic centimeter. Specimens of feces from the food handlers involved were examined for *B. typhosus*, *B. paratyphosus* (alpha and beta), *B. dysenteriae* and other members of the paratyphosus-enteritidis group but were found to be negative in all instances. Specimens of drinking water were found to have high bacteria colony counts (500 and 750 at 37 F and 1,000 and 500 at room temperatures), but these were negative for *B. coli*. None of the food poisoning (paratyphosus-enteritidis) group of organisms or staphylococci were found in the hazelnuts themselves or in the latter samples of ice cream, and the silver polish reacted negatively to the chemical tests for cyanide.

As a result of the investigations and observations described, certain of these conditions were corrected, the manufacture of ice cream aboard ship was discontinued, and the ice cream served to the passengers and crew was limited to that purchased and shipped aboard from inspected and controlled manufacturing plants located in ports of call ("shoreside" sources). Since the institution of these changes, there have been no further outbreaks of food poisoning aboard this vessel.

COMMENT

Although food poisoning has been traced to many different types of foods, milk and milk food products because of their inherent character certainly offer very favorable possibilities as the vehicular foods transferring the causative factors of food poisoning and certain transmissible diseases from their sources in man or animal to man. Even though it has been definitely proved on a number of occasions that many of the responsible organisms in these disorders withstand low temperatures and remain viable and capable of producing the disorder under ordinary circumstances, apparently there are still those who believe that freezing destroys microscopic organisms and renders the frozen food product medium sterile, innocuous and safe for the consumer. It is obvious however, to those who are interested in food poisoning and its prevention, and to those who are interested in food preservation, that the solution of the problem so far as ice cream and other milk food products are involved, lies in the same

methods that have been used to solve the problem in fluid market milk and in other foods and food products, namely, standard quality ingredients, cleanliness, appropriate sterilized equipment, proper use of heat (at 142-145 F or higher temperatures for at least thirty minutes), sterile containers and refrigeration as indicated or required. It must be realized by health officials as well as by the industry itself that low temperatures, as within the range of ordinary refrigeration and even very low temperatures in many instances, can be relied on only as inhibiting growth and multiplication of bacteria and certainly not as a method to destroy the organism present. It is essential, therefore, that every safeguard be utilized in the manufacture of ice cream and all other milk food products, with the same rigorous supervision and high standards that obtain in the production processing and marketing of high grade pasteurized market milk. Health officials will do well constantly to emphasize the importance of proper methods and the establishment of adequate safeguards.

SUMMARY

1 Interesting outbreaks of food poisoning, epidemiologically traceable to nut ice cream, occurred rather frequently aboard a large ocean liner sailing from San Francisco.

2 Laboratory studies revealed excessively high bacteria colony counts in specimens of the epidemiologically incriminated nut ice cream. The cultures showed *Staphylococcus aureus*, which may have been the causative factor, to be the predominant organism.

3 Investigations made by an observer-inspector, aboard for a regular trip, revealed many possibilities of contamination of the milk food product, which was made aboard ship.

4 The correction of certain undesirable practices and the use of ice cream from shoreside sources have resulted in no recurrence of food poisoning aboard this vessel.

CONCLUSION

Since the lower temperatures used in ordinary refrigeration and ice cream freezing have only growth-inhibiting and not bacteria-destroying power, and since milk and milk food products, because of their inherent character, offer excellent bacteria culture medium possibilities, ice cream and other milk food products should be subject to rigorous standards in production, processing and marketing, with the provision of every reasonable safeguard to the public health.

101 Grove Street.

The Four Hundred Eggs—All the eggs which are to be used throughout the woman's reproductive life are present in her ovaries at birth, and even before this. Not only that but nature gives her an enormous reserve supply, for each ovary starts out in life with a supply of something like 100,000 of these ova, far more than can ever be used for purposes of possible conception. As a matter of fact, since only one egg is ordinarily given off during each menstrual cycle and since the average duration of the woman's menstruating life is about thirty-two or thirty-three years not much more than 400 eggs are actually extruded from the ovary and are thus exposed to the possibility of fertilization by the male germ cell and only one of five hundred ova achieves admission to this aristocratic four hundred. With the male, nature is even more prodigal in her factor of reserve, for each ejaculation of the male semen is the amount of semen given off by the male in intercourse, contains about 226,000,000 spermatozoa. And yet only one of these is necessary for fertilization.—Novak, Emil. *The Woman Asks the Doctor*, Baltimore, Williams and Wilkins Company, 1935.

Clinical Notes, Suggestions and New Instruments

EMPHYSEMA OF THE CECUM

LEO L. HARDT, M.D., CHICAGO

There have been relatively few cases of intestinal emphysema reported in the literature. Those which have been reported have been associated either with an acute inflammatory process as a result of infection of the intestinal tract, or with injury or some congenital abnormality in conjunction with an inflammatory process. Mackenzie¹ in 1894 reported a case of emphysema of the jejunum. Numerous vesicles of air were found in the submucous tissue and the whole mucous membrane was congested. Hemorrhage into the intestine had taken place and no cause could be found. The patient had acute and chronic pulmonary tuberculosis, but there were no signs either of ulceration or of tubercles in the intestine. Nitch and Shattock² in 1919 reported two such cases. These authors attempted without success to place the etiology of their cases and made extensive studies. The possibilities suggested and ruled out by them were as follows: (1) bacterial infection by *B. aerogenes*, *B. oedematis*, *B. oedematis-maligni* or *B. coli*, (2) gas secretion from the tissue lymph, (3) osmosis, and (4) trauma, either mechanical injury or ulcer or perforation. Twyman³ in 1919 reported a case of emphysema of the cecum and believed it to be due either to the obstruction that he found or to bacterial infection. Lohr⁴ in 1929 reported a case and showed it to be the result of a secondary gas edema of the stomach and bowel due to an infection with the paranthrax bacillus.

REPORT OF CASE

F. C., a man, aged 29, a mechanic, admitted to the hospital, Jan. 23, 1934, had consulted a physician one year before because of stomach trouble, the complaint being gas and bloating in the upper quadrant of the abdomen, with moderate distress. He stated that he was always hungry and could eat any time of the day. At that time the condition was diagnosed as ulcer of the stomach. The distress continued to occur practically every day for a year. Alkaline powders were prescribed, which seemed to relieve the pain and hunger sensations; the symptoms recurring whenever the powders were discontinued. After several months the symptoms in the upper part of the abdomen disappeared, but the patient still had gas and flatulence.

Three days before admission to the hospital he was seized with a severe attack of pain in the right lower quadrant, which after a few hours radiated all over the abdomen and caused him to double up. There was no nausea and no vomiting. He had chills and thought he had a fever on the first day. The pain and rigidity continued up to the time of admission to the hospital. The patient was well developed and apparently in acute distress. The physical observations were negative except for marked tenderness and rigidity of the right lower quadrant of the abdomen. The blood pressure was 120 systolic, 70 diastolic. The temperature was not elevated. Examination of the urine showed a specific gravity of 1.030, an alkaline reaction, and no albumin, sugar, pus or casts. The blood count showed a hemoglobin of 80 per cent, 4,800,000 erythrocytes and 13,100 leukocytes. The differential blood smear revealed 22 per cent lymphocytes, 4 per cent large monocytes, 5 per cent transitionals, 64 per cent neutrophils and 4 per cent eosinophils.

Operation was performed by Dr. R. B. Malcolm. A right rectus incision was made, the anterior sheath was opened, the muscle was displaced laterally, and the posterior sheath was opened. When the peritoneal cavity was entered, no fluid was found. Exploration showed a thickening of the medial and lateral areas of the ascending colon, commencing just distal to the ileocecal valve and extending distally for a distance of about 10 cm., beginning and ending abruptly. On palpation

this thickened area was crepitant and felt exactly like lung tissue. There was no inflammation except a slight hyperemia, and no peritonitis. The appendix was normal. Exploration of other abdominal contents revealed nothing abnormal. Appendectomy was done. There was no odor and no evidence of perforation. There were simply air vesicles of the subserosa. Longitudinal incisions were made on each side, and the air escaped. Two lymph nodes were removed for culture. The air seemed not to invade the subserosa on the anterior surface of the colon but remained in the mesenteric portion, apparently coming from behind and partially encircling the bowel.

Twenty months later, in August 1935, the patient returned for further observation. The only complaint at this time was occasional slight constipation and a moderate degree of flatulence. There were no other gastro-intestinal symptoms. Physical examination was negative. The systolic pressure was 108, diastolic 68. A blood count showed hemoglobin, 90 per cent, erythrocytes, 4,890,000, leukocytes, 8,400, lymphocytes, 25 per cent, large monocytes, 6 per cent, transitional cells, 1 per cent, neutrophils, 66 per cent, eosinophils, 2 per cent.

COMMENT

I have been unable to find in the literature any cases in which the physical signs and symptoms pointed toward an acute inflammatory process and in which a true emphysema, before death, was found in the absence of injury, congenital abnormality or noticeable infection. In this case a pinpoint rupture of the intestine was considered at the time of operation, but nothing was found that substantiated this view. There had been no history of the taking of enemas. Cultures from the sites of the air blebs were negative. As stated, the appendix was removed and found to be normal. A careful examination of the stomach and gallbladder was made, in view of the early suspicion of possible ulcer or gallbladder infection, and there was no evidence of either past or present stomach or gallbladder disease. The question of a vasomotor disturbance based on allergy was also considered. A careful inquiry was made as to any previous history of allergy, with negative results.

CONCLUSIONS

This case we believe to be a true emphysema of the cecum, uncomplicated by inflammation, trauma or congenital abnormality, and without any known etiology.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

COPELAND REFRACTASCOPE ACCEPTABLE

Manufacturer: Bausch & Lomb Optical Company, Rochester, N. Y. Distributors: Riggs Optical Company, Chicago.

The Copeland Refractascope is a modified, self-luminous retinoscope, in which is incorporated a special electric bulb operating on 2½ volts, constructed with a special filament, bent to produce a linear source of light. According to the firm, the filament does not bend when used but may bend if the instrument is accidentally jarred or falls to the floor. The lamp socket into which this bulb is

Copeland Refractascope

fitted is incorporated in a movable bakelite support. It can be rotated through a 180 degree arc and moved to or from the condensing lens in the head of the instrument.

On the outside of the handle of the instrument is a sleeve, connected directly to the bakelite lamp support by means of a screw which places the control of the rotation and movement of the lamp by the operator in a convenient position.

The movement of the source of light to or from the condensing lens changes the angularity of the rays reflected from the mirror in the instrument, causing them to become divergent and convergent. Thus, when the sleeve is at the bottom the rays are most convergent and cross at a point approximately

¹ Mackenzie, H. W. Tr. Path. Soc. Lond. 46: 61, 1894.
² Nitch, C. A., and Shattock, S. G. Proc. Roy. Soc. Med. 12: 46 (Sec. Path.) 1919.
³ Twyman, E. D. Emphysema of the Cecum. J. A. M. A. 73: 1840 (Dec. 13) 1919.
⁴ Lohr, W. Arch. f. klin. Chir. 155: 188, 1929.

9 inches in front of the instrument, producing a "concave mirror effect" The sleeve at its highest position causes the rays to be divergent, which produces a "plano mirror effect"

The Copeland Refractoscope was tested by an investigator for the Council He reported the instrument as satisfactory

In view of the foregoing, the Council on Physical Therapy voted to include the Copeland Refractoscope in its list of accepted devices

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

CERTAIN MANUFACTURERS HAVE SENT ADVERTISEMENTS TO THE MEDICAL PROFESSION SUGGESTING THE USE OF VITAMIN A IN THE PREVENTION OF AND EVEN IN THE TREATMENT OF RENAL CALCULI SINCE THIS ISSUE HAS BEEN RAISED UNNECESSARILY, THE COUNCIL FELT IT ADVISABLE TO PUBLISH A REPORT ON VITAMIN A AND URINARY LITHIASIS THE FOLLOWING REPORT HAS THEREFORE BEEN AUTHORIZED BY THE COUNCIL FOR PUBLICATION

PAUL NICHOLAS LEECH, Secretary

VITAMIN A AND URINARY LITHIASIS

Urinary calculi were known in remote antiquity and have been studied as to cause and treatment throughout many centuries¹ Most of the possible or likely etiologic factors have been given serious consideration and support by different investigators at various times Many lectures reviews and treatises² on this phase of the subject have been published Among the most important of the factors suggested are heredity³ climate,⁴ restriction of the amount of water and its composition (the indirect influence of soil),⁵ food,⁶ infection, both focal, with remote effects in the urinary system,⁷ and direct, local,⁸ other noxious agents,⁹ and urinary stasis¹⁰ Some of these views are hardly susceptible of proof¹¹ and other views have been definitely opposed, as, for example, the view that focal infection¹² or local infection¹³ is the primary agent or even that they play any part in the process¹⁴ The problem must therefore still be considered unsolved That some abnormality of diet, for example, excess of mineral elements, improper

balance of its constituents, especially the inorganic elements, presence in it of some special stone producing substance or other conditions affecting the diet might be the cause has been considered for a long time The idea, however, that a specific deficiency of the diet might be the cause is relatively recent and is the direct outcome of observations and experiments made on animals¹⁵

Since the first mention,¹⁶ in 1910, of the occurrence of urinary calculi in the rat, much work has been done to determine their origin and mode of formation in this animal, partly at least in the hope that any knowledge so gained might throw light on the cause and mechanism of the formation of stones in man Osborne and Mendel¹⁶ in 1917 were the first to draw attention to the probability that a deficiency of a vitamin may be, at least indirectly, responsible for the formation of phosphatic urinary calculi in the rat Their experimental diets were very deficient in what are now known as fat soluble vitamins A, D and E, by no means rich in the water soluble vitamins B and G, and entirely deficient in water soluble vitamin C At that time they suggested that the calculi might be due, indirectly, to the effect of a deficiency of the fat soluble group of vitamins Although many of the investigators who have repeated and confirmed this work have narrowed the effect down to vitamin A,¹⁷ this conclusion was unjustified, because the diets which they used were the same as or similar to those used by Osborne and Mendel, or in certain instances even more deficient in some respects Some investigators who have used the same or similar diets have been cautious and have concluded that deficiency of vitamin A probably played a part in the production but was not the exclusive cause of the calculi which they observed¹⁸ Bliss, Livermore and Prather¹⁹ are the only investigators whose experiments justify their conclusion that deficiency of vitamin A alone can induce the development of urinary calculi in rats For the rat, their diet was deficient in vitamin A alone But other investigators who have also used a diet deficient only in vitamin A have not observed the formation of calculi, and, what is more important in this connection, investigators²⁰ have observed the formation of calculi in rats fed on diets that contained vitamin A in abundance These investigators concluded that a general deficiency of the diet, with an absolute or relative excess of calcium, as compared with phosphorus, was the cause of the formation of the calculi which they found McCarrison²¹ found that the addition of vitamin A or of vitamins A and D to a diet deficient in vitamins A and D, with a disturbed balance of calcium and phosphorus, reduced the incidence of calculi but did not prevent their formation He concluded that the administration of vitamin A played an important but not an exclusive part in the prevention of calculi composed of calcium carbonate and calcium hydroxide, which otherwise occurred with great frequency in rats fed on the diet mentioned

That deficiency of vitamins A and D together is a sufficient condition for the initiation of the changes that lead to the formation of urinary calculi in the rat can be accepted on the basis of the work done by those investigators who claim that the effect is due to deficiency of vitamin A alone,²² whose diet, however, was deficient in both vitamins A and D This conclusion can also be accepted by those who do not commit them-

selves²³ definitely to the idea that vitamin A alone is responsible but whose work shows that there was a deficiency of both A and D. Since the addition of phosphate (to balance the calcium and phosphorus in McCarrison's²⁴ diet) failed to prevent stone formation, although it reduced the incidence, this also shows that the diet which was now deficient only in vitamins A and D induced the formation of calculi. However, McCarrison²⁵ hypothesized the existence of some additional unknown stone producing agent in the cereal used in the diet. Practically all investigators are agreed that calculi do not occur in rats or dogs fed on a diet in which the inorganic elements are balanced and which contains an adequate amount of vitamins A and D.

That deficiency of vitamin A alone is a sufficient condition for the formation of urinary calculi in the rat cannot be accepted without reservation. To establish this beyond question will require further experiments like those of Bliss, Livermore and Prather,¹⁰ in which rats and other animals are fed synthetic diets complete in all respects except for a deficiency of vitamin A. The small amount of experimental work done in this connection on the dog²⁶ has served to show merely that dietetic deficiency may play a part in the formation of calculi.

That dietetic deficiency plays a part has been suspected and suggested for man also but, in this country at least, the existence of a serious deficiency of vitamin A in the diet of human beings with urinary stones has certainly not been demonstrated. It would be much easier to make a case for deficiency of vitamin D. The mere fact that urinary calculi are much less common, especially in children, than they were a century ago does not prove that vitamin A deficiency was the cause and that the more abundant use of sources of this vitamin has accounted for the decreased incidence. There have been so many changes in diet and general hygiene in that period that it is hardly fair to single out vitamin A without more adequate evidence. The report of Padua²⁷ pointing out the occurrence of cystolithiasis among Filipinos merely shows the probable effect of general dietetic deficiency and not that of one single vitamin. As a matter of fact he attempted to show some correlation with the occurrence of beriberi, which is due to a deficiency of vitamin B. All this is both pertinent and important, because it indicates the danger of applying to man what is not yet fully established for animals.

That deficiency of vitamin A is a necessary condition for the formation of stones in the urinary tract of the rat is certainly not established. Indeed, there is good evidence to show that this is not the case. By giving excess of magnesium carbonate, Watchorn²⁸ succeeded in inducing the formation of urinary calculi composed of calcium and magnesium phosphate in rats fed on a diet that contained an abundance of vitamin A and was otherwise complete in all respects for this animal. McCarrison,²⁹ Ranganathan³⁰ and Grossmann³¹ also showed that calculi occurred in rats fed on a diet containing vitamin A or vitamins A and D, with an excess of calcium and insufficient phosphorus. McCollum, Simmonds and Becker³² observed urinary calculi in many rats fed on diets containing an abundance of vitamins A and D and an excess of calcium. Ebstein and Nicolaier³³ and Keyser³⁴ found urinary calculi in rabbits

and dogs fed on a supposedly normal diet to which was added oxamid, a crystalloid foreign to the urinary tract. Since they did not give details of the composition of the diet they used, there is no assurance that it contained an adequate amount of vitamins A and D.

If deficiency of one or more vitamins is responsible for the building of stones in the urinary tract of the rat, how does it produce this effect? Many of those who believe that deficiency of vitamin A alone can do it, and those who believe it plays a part, have suggested two main methods, which may act in combination. 1 The calculi form because deficiency of vitamin A in the rat results in keratinization and desquamation of the lining epithelium of the urinary tract, a process that supplies the organic nidus for the deposit of crystalloids.³⁵ 2 The calculi form because deficiency of vitamin A in the diet results in strong urinary alkalization³⁶ either as a primary effect or secondary to infection.

It may be that this alkalization affects the physicochemical condition, chiefly the balance of protective colloids, of the urine, which, it is claimed,³⁷ favors precipitation of the crystalloids. This mechanism of precipitation of urinary crystalloids is denied by some investigators.³⁸ It should be obvious at once that all this applies only to the possible origin of stones that form in an alkaline medium and that it cannot apply to those that do not form in such a medium. It pertains to the types of stone most commonly found in the urinary system of the rat. Practically all investigators³⁹ are agreed that these are composed mainly of phosphates and carbonates of calcium and magnesium, when the diet is deficient only in vitamins A and D, and of calcium carbonate and calcium hydroxide, when, in addition, the diet contains an excess of calcium. Since urinary calculi in man, especially renal, are by no means always of this composition or formed in an alkaline medium, this again indicates the danger of applying to man what has been learned from a study of the rat. This is particularly true in consideration of the possible medical management of urinary, especially renal, lithiasis.

Up to the present time, only Saiki,⁴⁰ Fujimaki⁴¹ and Higgins⁴² have claimed the effective solution of experimental urinary calculi in the rat and dog²⁶ by the administration of a source of vitamin A. Actually they administered a source of vitamins A and D to produce the solution of the calculi, and the experimental diets which they used for the production of the stones were deficient in both of these vitamins. Higgins⁴² has also claimed success in the solution of urinary calculi in man. This has been done by the administration of a diet with an acid ash and a liberal amount of several sources of vitamins A and D. According to Higgins, partial or complete solution of renal calculi has been accomplished in twenty-one cases. Partial solution of calculi by medical means would accomplish but little, except perhaps in the case of impacted ureteral or pelvic stones, the passage of which might thereby be aided. Since Higgins did not try the effect of the acid ash diet alone or of each of the vitamins alone, it is difficult to draw any conclusions from these experiments on man about the value of

each of the three factors used for the partial or complete solution of the calculi. It is not possible to determine from his results whether all three are necessary, and certainly his studies do not justify the conclusion that vitamin A alone was responsible for the effect or even that it played an important part.

It is strange that neither Higgins nor any other investigator has studied the possible concretum producing properties of a diet with an alkaline ash, but otherwise complete in all respects, or the effect of administering only an acid ash diet to rats with calculi in the urinary system developed on a diet deficient in vitamins A and D or, better, deficient in only one of these vitamins. This should be done, because Higgins⁴³ showed that the addition of ammonium chloride alone to his stone producing diet reduced the incidence of urinary calculi. A definite answer to all these questions would go far in helping to determine the justification for the medical treatment of urinary lithiasis and for the unavoidably long delay which this causes if surgical intervention must eventually be employed.

In view of the foregoing considerations, the Council decided that the existing evidence does not warrant claims for the use of any of the vitamins, and particularly of vitamin A, in the prevention or treatment of urinary lithiasis and, further, that no such claims may appear in the advertising of accepted products.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

CELLU LOGANBERRIES PACKED IN WATER WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Eugene Fruit Growers Association, Eugene, Ore.

Description—Canned cooked loganberries packed in water without added sugar or salt.

Manufacture—The method of manufacture is essentially the same as for Cellu Blackberries Packed in Water Without Added Sugar or Salt (THE JOURNAL, Sept. 28 1935, p 1039)

| <i>Analysis</i> (submitted by distributor) — | per cent |
|--|----------|
| Moisture | 89.2 |
| Total solids | 10.8 |
| Ash | 0.4 |
| Fat (ether extract) | 0.6 |
| Protein (N × 6.25) | 1.0 |
| Reducing sugars as invert sugar | 3.5 |
| Sucrose | 0.1 |
| Crude fiber | 2.0 |
| Carbohydrates other than crude fiber (by difference) | 6.8 |

Calories—0.4 per gram 11 per ounce

Claims of Distributor—For diets in which sweetened fruit is proscribed

MELCOSE

Manufacturer—The Baker Laboratories, Inc. Cleveland.

Description—A canned sterilized homogenized mixture of partially evaporated milk, corn syrup (essentially dextrins, maltose and dextrose) and ferric ammonium citrate, U S P

Manufacture—The whole milk used is produced by tuberculin tested herds inspected by the Cleveland City Board of Health and is regularly tested by city and Baker Laboratory inspectors. On receipt at the factory the milk is inspected, weighed, pumped into holding vats drawn into hot wells, heated to boiling, concentrated in vacuum pans to half its

original volume, homogenized and cooled, and the corn syrup and the ammonioferric citrate are added. The mixture is adjusted to standard composition by laboratory analysis, automatically canned, sealed, and sterilized at 116-118 C. for thirty minutes.

| <i>Analysis</i> (submitted by manufacturer) — | per cent |
|---|----------|
| Moisture | 70.1 |
| Total solids | 29.9 |
| Ash | 1.3 |
| Fat | 6.4 |
| 1 rotein (N × 6.25) | 5.4 |
| *Dextrins | 4.7 |
| *Reducing sugars as maltose | 3.0 |
| *Dextrose | 1.0 |
| Total carbohydrates (by difference) | 16.8 |
| Iron (Fe) | 0.002 |

* Estimated from formula and analysis of corn syrup

Calories—1.5 per gram 43 per ounce 47 per fluid ounce

Claims of Manufacturer—For use in infant feeding under the directions of a physician.

JEFFERSON ISLAND EVAPORATED FREE RUNNING IODIZED TABLE SALT

Distributor—Jefferson Island Salt Company, Inc., Louisville, Ky

Manufacturer—Jefferson Island Salt Mining Company, Inc., Jefferson Island, La

Description—Table salt containing 1 per cent added magnesium carbonate and 0.02 per cent potassium iodide

Manufacture—Salt containing 1 per cent magnesium carbonate prepared as described for Jefferson Island Evaporated Free Running Table Salt (THE JOURNAL, Oct. 5, 1935, p 1119), is admixed with potassium iodide and automatically packed

| <i>Analysis</i> (submitted by manufacturer) — | per cent |
|---|---------------|
| Moisture | less than 0.1 |
| Calcium sulfate | 0.1 |
| Calcium carbonate | 0.03 |
| Magnesium carbonate | 0.9 |
| Potassium iodide | 0.025 |
| Sodium chloride (by difference) | 98.9 |
| Silica | 0.006 |

Claims of Manufacturer—For all table and cooking uses. The added magnesium carbonate tends to preserve free running qualities. The iodine in the salt aids in preventing simple goiter caused by insufficient iodine in the diet. Used daily as the only salt on the table and in cooking, it richly supplements the iodine of diets deficient in that element and thus helps to protect against simple goiter.

1 L C BRAND CRYSTAL WHITE SYRUP

2 L C BRAND GOLDEN SYRUP

Distributor—L C Mercantile Company, Inc., Mendota, Quincy, Springfield and Danville, Ill., and Fort Wayne, Ind.

Packer—American Maize Products Company, New York.

Description—1 Table syrup, a corn syrup with added sucrose syrup, flavored with vanilla. The same as Amaizo Crystal White Syrup (THE JOURNAL, July 16, 1932, p 224)

2 A blend of corn syrup and refiners' syrup flavored with vanilla extract. The same as Amaizo Golden Syrup (THE JOURNAL, May 16, 1931, p 1695)

Claims of Distributor—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

VERIFINE BRAND EVAPORATED MILK

Manufacturer—Verifine Dairy Products Company, Sheboygan Wis

Description—Unsweetened, sterilized evaporated milk. The composition and procedure of evaporation and canning are essentially the same as for the usual evaporated milk (THE JOURNAL, April 16, 1932, p 1376)

ORGANIC AND INORGANIC ARSENIC

Arsenic is one of the oldest of therapeutic substances, in certain forms, notably the sulfides, it has been therapeutically employed since the beginning of the Christian era. With its increasing use in the arts and industry, opportunity for arsenic poisoning, either accidental or with suicidal intent, has been progressively greater. Recently, however, much apprehension has been expressed over the possibility of chronic poisoning with arsenic through the use of its compounds in sprays for fruits and vegetables as well as in foods artificially prepared by the use of chemical reagents contaminated with arsenic. It seems likely that in the forthcoming revision of the pure food law more attention will be given to the amounts of certain of the toxic elements, such as arsenic, fluorine and lead, occurring in food materials.

Many of the so-called toxic elements as well as other more or less unusual metals are fairly constant constituents even of virgin soil, the ash of plants contains these elements. It is not surprising that the tissues of man and other animals are likewise found to have them as rather constant constituents. Thus arsenic has been found in human organs, the amount increasing with age, in normal human urine, and in blood, in which fluid it is said to increase during menstruation. In the case of certain of these "trace" elements, notably iron, copper and manganese, it has been shown that they play an indispensable part in the physiologic well being of the organism.

In view of the ubiquitous distribution of arsenic, considerable interest attaches to the recent report of Coulson, Remington and Lynch¹ in which the metabolism of arsenic in organic combination in certain marine food materials is compared with that of arsenic trioxide. A comparison of the arsenic content of shrimp from various Southern states showed a range of from 3.8 to 130 mg per kilogram of dry material. This permitted the use of experimental rations of both

high and low concentrations of arsenic, shrimp being used as well as the trioxide as the source of arsenic in separate diets. On the stock food extremely poor in arsenic, it was observed that albino rats stored increasing amounts of this element with advancing age, the study showed, furthermore, that the arsenic accumulates in the liver in higher concentrations than in the other tissues. It was shown that the bodies of the animals consuming the shrimp diet rich in arsenic contained from two to four times more arsenic than was present in the controls fed the stock ration, whereas the same amount of arsenic given as the trioxide induced a storage of about sixty times that in the controls. An examination of the absorption of the arsenic showed that less than 2 per cent of the shrimp arsenic was retained, when the trioxide was fed, roughly 80 per cent was retained. Ninety-six per cent of the absorbed organic arsenic was eliminated by the kidney, whereas the excretion was equally divided between urine and feces when the trioxide was given. Similar experiments on human subjects indicated that the degree of retention of the organic and inorganic arsenic was somewhat more nearly alike, though here again more remained in the body when the trioxide was ingested.

These observations indicate that the form of combination in which inorganic elements are presented to the organism may exert a profound influence on the metabolism of the element in question. A recent report² of the difference in the availability of the calcium from two different leafy vegetables further illustrates this thesis. It is obvious, in the light of some of the recent investigations in the field of nutrition, that the formulation of a tenable legal point of view regarding the limits of concentration of some of the toxic elements becomes increasingly difficult.

THE OLFACTORY TRACT AND EXPERIMENTAL POLIOMYELITIS

Epidemiologic and experimental evidence seem to indicate that the virus of poliomyelitis gains entrance to the central nervous system chiefly through the nasopharynx, probably by way of the olfactory nerve. It is an interesting fact that the olfactory nerve fibers are derived from cells situated actually on the surface of the body in the upper part of the nasal cavity. The fibers from the olfactory cells pass through the cribriform plate of the ethmoid bone to the olfactory bulb lying under the inferior surface of the frontal lobe of the brain. The terminal fibers of the nerve are therefore exposed to the external environment. Many years ago it was shown that poliomyelitis could be produced in monkeys by instilling the virus into the nose. Flexner and Clark found that within forty-eight hours after intranasal inoculation the olfactory lobes

¹ Coulson E J, Remington R E and Lynch K M. J. Nutrition 10: 255 (Sept.) 1935.

² Finke M L and Sherman H C. J. Biol. Chem. 110: 471 (July) 1935.

became infective. Poliomyelitis virus has been found in the washings or tissues of the nasopharynx in the experimentally produced disease, in the disease in human beings and in healthy contacts.

Not only were Schultz and Gebhardt¹ able to infect 95 per cent of monkeys inoculated with virus intranasally, but they offered experimental proof that the virus gained entrance to the central nervous system by way of the olfactory nerve. With an electric cautery they sectioned the region of the olfactory bulb and olfactory tract of six *Macacus rhesus* monkeys for a distance of about 2 cm. Fifteen days later they instilled intranasally poliomyelitis virus not only into these monkeys but also into three normal control monkeys. Out of the nine monkeys inoculated intranasally with poliomyelitis virus, only the control monkeys developed the disease, and all three of them did so on the seventh day. Schultz and Gebhardt repeated this experiment sixteen days later, again subjecting the six monkeys that had been operated on to three intranasal instillations of virus, this time using two control monkeys. The animals that had had operation again continued to remain well, while the two controls developed poliomyelitis on the seventh day. Three weeks after the second intranasal instillations, the monkeys submitted to operation were inoculated intracerebrally with poliomyelitis virus to test their susceptibility to the virus. All of them now developed typical poliomyelitis in from five to eight days.

The ingenious experimental work of Schultz and Gebhardt was recently confirmed by Lennette and Hudson,² who, months after sectioning the olfactory tracts of five *Macacus rhesus* monkeys, inoculated them intranasally with the virus. None of these monkeys showed any signs of poliomyelitis, whereas the nine controls whose olfactory tracts had not been sectioned succumbed to poliomyelitis after intranasal inoculation. The Chicago investigators furthermore inoculated five monkeys that had had operation and five normal animals with poliomyelitis virus intravenously on three successive days. None of the animals whose olfactory tracts had been severed showed any evidence of infection, while four of the five control animals succumbed to poliomyelitis. An interesting question arises. Was the virus excreted in the four monkeys from their blood stream onto the nasal mucosa? If so, it should be recoverable from the nasal washings. Continuing the investigation, Lennette and Hudson now gave to four immune and six normal monkeys intravenous injections of poliomyelitis virus on two successive days. The result was that none of the immune monkeys became infected while five of the six control monkeys died of poliomyelitis. On the second, fourth and sixth days of the experiment, the nasopharynx of each monkey was

washed out with sterile distilled water and the washings were pooled in groups comprising those from the immune animals and those from the controls. The pooled washings were passed through a Berkefeld N filter, then concentrated by boiling in vacuo and injected intracerebrally into test monkeys. These experiments were negative except in one animal, which received the pooled washings obtained on the fourth day from a group of normal monkeys. This monkey died of typical poliomyelitis. When the difficulty of detecting poliomyelitis virus in nasal washings is considered, the authors believe that the one positive result is significant.

Another interesting and possibly important experimental study on the prevention of poliomyelitis has been reported by Armstrong and Harrison³ of the U S Public Health Service. At varying times relative to the inoculations they instilled 1.5 cc of a 4 per cent sodium aluminum sulfate solution, alum, into the nostrils of a group of rhesus monkeys inoculated intranasally with poliomyelitis virus. The result was that of twenty-four alum-prepared monkeys only six died of poliomyelitis, whereas among twenty control animals sixteen died of poliomyelitis. The percentage of the two groups of monkeys surviving was therefore 76 and 16, respectively. The mechanism by which the alum exerted a protective effect in these experiments was not definitely determined. The authors believe that it was probably a decrease in the permeability of the mucous membrane of the nose rather than an antiseptic action. This method of prevention is not recommended for human use, however, further study in this direction may lead to effective methods of prevention.

STRUCTURE OF GLUTATHIONE

The progress made in the elucidation of the chemistry and physiology of biologically important substances determines the roles that can be assigned to these compounds in metabolic processes. In some instances, complete chemical knowledge and even synthesis of a compound provides a tremendous stimulus to the development of conceptions regarding its physiologic functions. This is seen, for example, in the large number of publications appearing on the biochemistry and physiology of vitamin C, the ready synthetic production of which in the laboratory, made possible by the establishment of its chemical constitution, has made this vitamin available for experimental and clinical use in the form of pure crystals (cevitamic acid). On the other hand, functional studies of physiologically important substances have often preceded the development of knowledge of their chemical identity, particularly when a type grouping in the compound may be responsible for its metabolic importance. This is true of the tripeptide glutathione, the sulfhydryl grouping of which

and the ready conversion of sulfhydryl to disulfide and back to sulfhydryl have led to the conception of its importance among the substances catalyzing body processes, particularly oxidations and reductions occurring in the tissues

The structure of glutathione was first established as a dipeptide, glutamylcysteine, and this configuration was later confirmed by synthesis. However, reinvestigations of the compound during recent years have clearly demonstrated the presence of a third amino acid, aminoacetic acid (glycine), in the glutathione molecule. Studies of glutathione and its degradation products have produced evidence that it is of the tripeptide constitution, glutamylcysteinyl-aminoacetic acid. Final confirmation of this evidence, however, awaited the synthesis of this substance and the establishment of the identity of the synthetic product with the naturally occurring tripeptide.

The preparation of cysteinyl and cystinyl peptides, that is, peptides in which the carboxyl group of these amino acids has been conjugated with the amino group of another amino acid, is attended with considerable difficulty, largely because of the lability of the sulfur in the molecule under the conditions generally employed in the preparation of peptides in the laboratory. However, the first synthesis of cystinyl peptides has recently been accomplished¹ by careful modification of the classic procedure of Bergmann and Zervas.² Both cystinyl-di-aminoacetic acid and cystinyl-dialanine were prepared in an analytically pure state, with the view to the application of a similar method to the synthesis of glutathione. The latter difficult achievement, however,³ has now been reported from the laboratory of Harrington,³ whose brilliant work in the establishment of the structure and synthesis of thyroxine placed him in the front rank of organic chemists investigating biologically interesting substances. Harrington and Mead have established the identity of their synthetic tripeptide, glutamylcysteinyl-aminoacetic acid, with the naturally occurring glutathione. At approximately the same time, confirmatory evidence of this structure has appeared⁴ in which the synthetic dipeptide cysteinyl-aminoacetic acid has been shown to be identical with a dipeptide obtained from glutathione by a mild hydrolytic procedure. The latter investigation is of interest because it suggests still another method of approach to the synthesis of glutathione by procedures that may make available adequate amounts of this substance for research purposes. This would be of considerable value in investigations designed to add further information regarding the many important physiologic and metabolic functions already suggested for glutathione.

ADVANCE IN MEDICAL SCIENCE IN GERMANY

During the past year THE JOURNAL published a series of articles under the general title "Glandular Physiology and Therapy." This series attracted world-wide attention, requests were received from publishers and translators in seven nations for rights to translate and republish these articles. Among others came a letter from Germany to the effect that the publishers Urban and Schwarzenberg in Berlin were anxious to take over the publication of the book in German. These publishers were offered the same type of arrangements offered to those in other countries. Next came a letter requesting that there be forwarded to Germany the original German text of the paper by Aschheim, this and the article by Zondek were originally written in German and translated for the series in THE JOURNAL. In answer to this request, the copy was forwarded to the German translator. Now comes a letter from the translator reading "I have just received a communication from the publishers Urban and Schwarzenberg in which they inform me that they are unable to publish the planned translation of the series of articles on 'Glandular Physiology and Therapy' since it contains articles by former German professors." Eventually, no doubt, the effects of the return of medicine in Germany from modern science to medievalism will be reflected in the health of the German people.

HANDBOOKS FOR DEBATERS ON SUBJECT OF STATE MEDICINE

In the issue for October 19 THE JOURNAL called attention to some of the handbooks that have been prepared for the use of debaters in the discussion now going on in high schools and universities on the subject of state medicine. On November 12 a debate was held on the radio in which Mr. William Trufant Foster, director of the Pollak Foundation for Economic Research, and Bower Aly, director of forensics at the University of Missouri, discussed the affirmative and Drs. Morris Fishbein and R. G. Leland the negative. This debate is printed in full in the current issue of the *American Medical Association Bulletin*¹ and is available to physicians on request. Another debate handbook² has been prepared by the Debaters Information Bureau, with headquarters in Portland, Maine. Of this, J. Weston Walch is the compiler. It is produced in facsimile typewritten form and consists of about 158 pages, covering much the same ground as the handbooks previously referred to. Among the items recently made available by medical organizations is a mimeographed handbook³ entitled "A Digest of Sickness Insurance," prepared by the Chester County

1 The Radio Debate on State Medicine, *A. M. A. Bull.* **30** 113 (Nov.) 1935.

2 Complete Handbook on State Medicine. J. Weston Walch, chief compiler. Debaters Information Bureau, 45A Free Street, Portland, Maine.

3 A Digest of Sickness Insurance, Chester County Medical Society, West Chester, Pa. Copies obtainable for 30 cents postpaid from R. T. Devereux, M.D., 37 South High Street, West Chester, Pa.

Medical Society in West Chester, Pa This represents largely a compilation of material developed through the Bureau of Medical Economics of the American Medical Association The Wisconsin State Medical Association has prepared its own discussion outline⁴ for the use of physicians This outline also is developed from the pamphlets issued by the Bureau of Medical Economics and by the State Medical Society of Wisconsin and is supplemented by a tentative debate outline for high school use An elaborate handbook⁵ has also been prepared by the Minnesota State Medical Association This contains much material developed by Minnesota writers, with the belief, no doubt well founded, that Minnesota high school students and Minnesota audiences are more likely to be interested in what their own physicians are saying This, indeed, is a further demonstration of the confidence rightly to be held by the patient in his own physician Among the most interesting of the items in the Minnesota pamphlet is the article on "Guild" medicine by Prof Richard E Scammon—a fine scientific plea for the perpetuation of medical ideals and standards

NOBEL PRIZE IN MEDICINE

The Nobel prize in medicine this year was awarded to Prof Hans Spemann, ordinaris in zoology at the University of Freiburg-im-Breisgau, in recognition of his work on what is called the organ-producing effect By this effect is meant, for example, the action that a dissected portion of the upper lip of the primitive orifice of the larva of the water newt exerts on cells in its vicinity when it is transplanted to another portion of the body Apparently these cells obtain, through the action of the implant, a new quality, which permits them to act as the anlage or embryonic cells of the organ that would have developed at the spot from which the transplant was cut That is to say, there develops from these cells a primitive nervous system, an embryonic medullary tube, or perhaps the anlage for the spinal cord and brain The physical-chemical nature of this organ-producing substance is not yet established Spemann assumed at first that the living quality of the transplant was an essential factor in its effect He discovered, however, that the effect is produced also by a dead explant and that under certain circumstances the tissue of the explant may be replaced by other substances These experiments would seem to constitute the beginning of knowledge of the causes of organ development from definite portions of the embryo They are of great biologic significance The Nobel prize winner, Spemann, who is now 66 years of age, was formerly a zoologist at the University of Rostock In 1914 he was appointed assistant director of the Kaiser Wilhelm Institut für Biologie in Berlin-Dahlem, and since 1919 he has occupied the chair of zoology at the University of Freiburg-im-Breisgau He is also editor of the *Archiv für Entwicklungsmechanik*

PRESENT STATUS OF THE PRACTICE OF MEDICINE IN THE UNION OF SOCIALIST SOVIET REPUBLICS

ARNOLD L LIEBERMAN, M D, PH D
GARY IND

What with wishful thinking, plain ignorance and sheer propaganda, there is such a cloud of confusion on the present-day status of the practice of medicine in the Soviet Union that it seems desirable to put down what facts can be actually verified from unimpeachable official sources and personal observation The material was gathered while I was visiting Russia incidental to the fifteenth International Physiologic Congress I was given every facility to come and go freely As I speak the language, I needed no interpreters or guides My expenses were all defrayed by myself

In order to obtain a fair background of the present situation, one must first grasp the fundamental fact that the Soviets inherited a country endowed with only a meager medical system According to the Great Russian Encyclopedia (volume 31), in 1913 within the confines of the present Russian Federated Socialist Soviet Republic there were listed only 13,154 physicians There were only 37,476 nurses The great bulk of this personnel was concentrated in the larger cities The vast village population was left, practically speaking, to its own devices Whole counties had a couple of nurses as its entire medical staff As a result of the World War and the disastrous civil wars, but little of even this personnel was left over The absence of medical aid and the breakdown of civilized standards led to successive waves of epidemics of cholera, typhus, malaria and similar scourges

In an effort to organize medical cadres as rapidly as possible, the Soviet government proceeded to organize "rapid courses" of training The procedure was roughly like this A promising young peasant or worker was sent through a three year workers' faculty" He received the three R's and the rudiments of a high school course He was paid all the time by the government exactly as if he had continued on his previous job The more talented of the graduates of these faculties were then sent to special condensed medical courses, which would turn out medical graduates in three and one-half years or, in case of "sanitation specialists," in as little as two and one half years No laboratory work of significance and no equivalent of an internship was provided Kaminsky—the commissar of national health—in his authoritative report to the sixteenth All-Russian Congress of Soviets frankly states that the work done by these graduates is "completely inadequate" By early 1935 there was a total of about 53 000 graduate medical men and women in Russia roughly about 46 per hundred thousand of population

In return for having his way paid through school, the graduate is obligated to go to any post assigned to him for the next five years This has meant the village or small city As a result, the country as a whole is acquiring some type of medical man for the first time in its history In actual training he is not better than a superior nurse in the United States, but he has been able to cope, at least in part, with the various plagues, so that mortality and morbidity statistics are showing marked improvement over fifteen years ago although, of course not on a par with comparable statistics in our country

Steps have now been taken to improve the medical graduate. Kaminsky in the report already referred to enumerates the results of the decree of Sept 3, 1934 1 A standard minimum five year course 2 Increasing stipends to teaching staffs and students from 40 per cent to 90 per cent in an effort to ameliorate living conditions 3 Sums running into millions of gold rubles

being spent on creating adequate laboratory and classroom facilities 4 Fairly stiff government examinations before graduation to ensure the quality of the new men 5 Increase in the number of teaching institutions with the aim of ensuring 7,000 new doctors annually All these things are not mere paper dicta, as numerous new buildings are actually going up in Leningrad, Moscow, Kharkov, Kiev and other medical centers of the country If uninterrupted, this program should lead to substantial results in the near future It is to be hoped that this decree will rapidly eliminate the poorer schools which arose out of the necessities of the immediate postwar years

The actual present status of medical aid to the population presents an uneven picture, with generalizations being subject to revision almost monthly In the villages, nuclei of medical practice are being established The young medical graduate is better than nothing at all and he certainly is a focus of some sanitary instruction One can see that in his crude little room or two he is doing excellent pioneer work in smallpox and typhoid control, child care, elementary sanitation, civilizing habits of cleanliness and so on While, on the average, he is doing no surgery and committing countless errors of diagnosis and treatment, still he is a beneficent village influence that was absent twenty years ago

He is aided by the "middle medical personnel", i e, the 'feldsher' (assistant to the physician) and the nurse Many a village in the absence of a doctor receives its entire medical care from these individuals There are close to 150,000 of them today Their average seems to be of quite low standards Kaminsky, again in all frankness, regretfully says that "their training has been a neglected and forgotten field"

At this point I might mention in passing that there is an acute shortage of most indispensable drugs "Paint them iodine and mark them duty" becomes a grim jest when even digitalis and ether are hard to get Again Kaminsky tells of the steps being taken to ameliorate this grave handicap

In the cities the situation is much better The organizational plan is quite simple in theory The city is divided into numerous small districts One or more physicians are on duty all the time in each district to make house calls Then there are polyclinics for ambulatory patients and hospitals for the very ill The whole organization is completely centralized in Moscow, with local units having autonomy only in details Leningrad, with a population of 2,700,000, may be taken as an example This city has 110 outpatient clinics During 1934, 16,290,715 individual calls were made at them Smallpox vaccination is universal More than 700,000 protective typhoid series were given The water supply of the city has been safeguarded by chlorination Milk is pasteurized, but control at the source is admittedly inadequate Food is being inspected at the plants Infant care is an absorbing problem Infant mortality has fallen from 22 per cent before the war to 14 per cent this year Maternal mortality is quite low Abortions are entirely legal, although socially condemned There is extensive birth control education The net of "crèches" or nurseries at factories is being extended as rapidly as possible There are 157 of these, with 11,245 cribs There are sixty-three hospitals with a total of 21,285 beds During 1934 these had 388,678 admissions, with a total of 7,060,985 bed days There are in the entire city 8,780 medical posts with 6,331 doctors available, of whom 519 have had only the "sanitary course" and so are not really physicians in our meaning of the word

Of the city's hospitals the Metchnikov Institute is considered on a par with the best It has 2,500 beds There is no provision for psychiatric, contagious or pediatric cases It approaches in general appearance Guy's in London or the Cook County Hospital in Chicago The director of the hospital is a non-medical man He hires and fires the junior staff The chiefs of departments are appointed direct from Moscow It is a teaching institution with 180 doctors among its 2,000 employees

The mortality at Leningrad has dropped from a peak of 771 per 10,000 in 1919 to 149 per 10,000 in 1934 Tuberculosis is the most important single cause of death 22.7 per 10,000

Dr Bogin, the chief of the Leningrad Health Bureau (and authority for the figures just given) dwelt frankly on their outstanding practical difficulties Because all calls are free, there is an enormous wastage of effort on trivial complaints. Consideration is being given to making a nominal charge for polyclinic calls and a larger charge for house calls in order to reduce the pressure of work on the staff There is insufficient incentive for the junior staff men to do good work They have only one doctor to 3,000 adults Many men in responsible posts are not well qualified Still he appeared optimistic and thought that they would surmount their present difficulties within the next few years Because of the high degree of centralization, there is a total absence of cultism and there are no complications with such organizations as the Anti-Vivisection Society, Also, the factory organizations were being made to realize their difficulties and were extending active practical aid in coordinating medical inspection at the various plants, giving them space, time and other considerations

The economic status of the Russian doctor is still quite bad, although no longer as impossible as it was before the decrees of 1934, already mentioned, and the supplementary law of March 1935 The average doctor today receives from 300 to 400 rubles per "job" If he holds two posts (as many do) he may receive between 600 and 700 rubles a month. A senior staff member may get from 1,000 to 5,000 rubles a month. Furthermore, about 10 per cent of the doctors do private consulting work This is the only nonsocial medical practice still surviving in Russia Because of the low quality of the new graduates, many members of the new bureaucracy, better paid engineers, and so on, when they become ill, ask to have certain men to examine them This they can do by paying the consultant out of their own pocket In practice this means that some of the professors of medicine can earn as much as from 4,000 to 5,000 rubles a month

A word should be said here about what the ruble will really buy It is worth theoretically 87 cents However, it is an open secret that on the illegal "black bourse" a dollar will buy thirty paper rubles But it is really worth more Such an important item on the budget as rent is calculated on a percentage basis of one's salary Furthermore, certain articles of clothing and food were still obtainable in "closed stores" (for institutions employees only) at material reductions in price Bread in the summer of 1935 cost 1 ruble a pound A ten dollar suit cost 400 rubles An excellent theater seat is only 3 rubles. It should be noted that the Soviets are actively deflating the ruble prices are falling steadily If the crops this fall really turn out as they were expected to, further drastic reductions in the high cost of living will become highly probable For the present it would not be far wrong to say that the ruble is about on a par with the French franc This means that on a 400 ruble salary the doctor is earning around \$30 a month. This compares with the 125 ruble a month minimum for unskilled labor, from 200 to 300 for skilled labor from 400 to 600 for an average engineer, and up to 1,000 to 1,500 for the manager of the factory

The social status of the Soviet doctor is again a thing most difficult to evaluate The prewar graduate, the professor of medicine or surgery, the consultant busy practicing the art of medicine, unquestionably command an outstanding niche in Soviet society They constitute about 10 per cent of the profession The young graduate does not have, as yet either the ability or the culture to be in the front rank The average intelligent citizen is faintly contemptuous of his training and frankly fearful of his ministrations At present he seems to be regarded as somewhat better than a skilled artisan but certainly not on the level with a good engineer or a director An

impression cannot be evaluated precisely but is given as my reaction. As his technical quality improves and as his cultural stature grows his social standing will undoubtedly rise.

Summarizing briefly, it seems fair to say that there is today in Russia a medical service which, no matter how modest, is an enormous advance over prewar conditions. While qualitatively it is still very low grade, steps are being taken to remedy the situation in the near future. The Soviets have planned and are doing noteworthy things along the line of maternity care and infant welfare. Lack of space confines me to a mere mention of these excellent features. The average doctor is badly underpaid and terribly overworked. Practical steps are being taken to correct this. However, as of today, the free medical service is rather low grade. The care received by a patient who can afford to select and pay privately for his doctor is on a much higher plane. In practice this seems to mean that the higher brackets of income receive incomparably better service.

One cannot expect the impossible. Even with internal and external peace and general prosperity, the extension of medical education, practice and service to the Soviet Union as a whole at the standard we are accustomed to in our country could not be achieved in the short time that has elapsed since the Russian revolution. Considering their environment, the Soviets have accomplished much. If the economic regeneration of Russia continues, there will be a steady rise in medical standards. But many of their fondest hopes will have to be realized before we shall be able to apply our yard stick and find comparable values.

Association News

APPLICATIONS TO COMMITTEE ON SCIENTIFIC RESEARCH FOR GRANTS

The Committee on Scientific Research of the American Medical Association invites application for grants of money to aid in research on problems bearing more or less directly on clinical medicine. Preference is given to requests for moderate amounts to meet specific needs. For application forms please address the committee at 535 North Dearborn Street, Chicago.

RADIO BROADCASTS

The American Medical Association broadcasts over the Blue network and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers a toast: "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The next three programs are as follows:

December 17 Animal Diseases in Man W. W. Bauer M.D.
December 24 No broadcast
December 31 No broadcast.

This program is broadcast also on the short waves through KDKA Pittsburgh over station W8XK, 11,870 and 12,210 kilocycles.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Annual Registration Due January 1—Every person practicing medicine, surgery or osteopathy in Arizona is required by law to pay annually on or before January 1, to the board of medical examiners, a renewal license fee of \$3. Any licentiate who does not renew his license as required is to be penalized \$1 for each day that he practices without a renewal license, not to exceed \$50. The board of medical examiners is to revoke the license of any licentiate who fails to renew his license for three successive years.

ARKANSAS

Society News—A symposium on the menopause was presented before a joint meeting of the Garland and Sebastian county medical societies in Fort Smith, October 8, speakers were Drs. Walter G. Klugh, Arthur G. Sullivan, George B. Fletcher, Charles H. Lutterloh, William E. Gray and Gaston A. Hebert, Hot Springs National Park. The Garland County Medical Society participated and the Army and Navy Hospital cooperated in the fifth annual conference of the Leo N. Levi Memorial Hospital and the Charles Steinberg Clinic in Hot Springs National Park, October 15-16. Speakers included Dr. Joseph Earle Moore, Baltimore, "Diagnosis and Treatment of Neurosyphilis"; Dr. William B. Long, New York, "Medical Aspects of Syphilis in a General Hospital"; Chester N. Myers, Ph.D., New York, "Functional Disturbances of the Liver Following Antisyphilitic Therapy"; Hepatitis and Acute Yellow Atrophy. The Benton County Medical Society was addressed in Rogers, October 10, by Drs. Francis Walter Caruthers and George F. Jackson, Little Rock, on treatment of fractures and common diseases of the skin and their treatment, respectively.

CALIFORNIA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$2. Failure to pay the required fee within sixty days after January 1 works a revocation of a license and thereafter a license may be reissued only after application and the payment of a \$10 penalty.

Symposium on Heart Disease—The Los Angeles County Heart Association held its fourth annual symposium, December 6-7, in Los Angeles. A joint session with the Los Angeles County Medical Association was a feature of the program in the evening of the first day. Dr. Howard F. West, Los Angeles, presented "The Challenge of Arteriosclerosis," and Dr. John J. Sampson, San Francisco, "The Relation of the Autonomic Nervous System to Normal and Diseased Heart Function." The concluding session, Saturday morning, was given over to a clinical pathologic conference, case reports by clinicians and necropsy reports and demonstrations of specimens by pathologists.

Society News—Dr. Louis E. Phaneuf, Boston, discussed "Surgical Treatment of Uterine and Vaginal Prolapse" before the Los Angeles Surgical Society at the annual dinner meeting, December 13. At a meeting of the Orange County Medical Society in Orange, October 1, Dr. Karl E. Kretzschmar, Los Angeles, discussed "The Injection Treatment of Hernia." Speakers before the Riverside County Medical Society in Riverside, October 14, were Drs. Samuel Ayres Jr. and Norman J. Kilbourne, Los Angeles, their papers were entitled "Infections of the Skin—Bacterial, Fungous and Parasitic" and "Elimination of Pain After Rectal Operation and in Rectal Treatment," respectively. Dr. John B. Doyle, Los Angeles, discussed chronic alcoholism before the Santa Barbara County Medical Society in Santa Barbara, October 14. Dr. Jay Marion Read has been chosen chairman of the heart committee of the San Francisco County Medical Society, Dr. John P. Strickler vice chairman, and Dr. Amos Christie secretary. The committee sponsors the annual heart symposium of the society, which this year was held November 20-21.

CONNECTICUT

Dr Linde Named Health Officer of New Haven—Dr Joseph I Linde, clinical professor of pediatrics, Yale University School of Medicine, has been appointed health officer of New Haven, succeeding Dr Leonard Greenburg, who recently resigned to become associated with the New York State Department of Labor. A graduate of Yale, class of 1908, Dr Linde is a past president of both the New Haven city and county medical societies. He is chairman of the committee on public health of the Connecticut State Medical Society and chairman for Connecticut of the American Academy of Pediatrics. He is 49 years of age.

Blood Test Mandatory in New Marriage Law—The Connecticut State Department of Health announces that after January 1 each person applying for a marriage license must under law have a blood test. Under the new law the applicant for a marriage license must let the family physician take a sample of blood, which he will send either to the laboratory of the state department of health or to one approved by the department. The test will be made and a report mailed to the physician on two forms, one, the usual laboratory report, for the physician to retain, and the other to be presented to the registrar. If the test is satisfactory the physician will sign his official statement and the applicant also signs, in the presence of the physician, the completed statement to be given to the registrar. On receipt of the physician's statement, the registrar will accept the application and on the fifth day following will issue the marriage license if both persons by that time shall have surrendered to him their physicians' statements. The department emphasizes that the blood test must be made not more than forty days before the license is issued, not forty days before the license is applied for.

FLORIDA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually on or before January 1, with the secretary of the state board of health, and at that time to pay a fee of \$1. A licentiate failing to register annually is liable to a fine of not more than \$50.

Society News—The Dade County Medical Society was addressed, November 1, by Drs Joseph H Luciman and William C Rentz, Miami, on 'Radiation Treatment of Middle Ear and Mastoid Infections and Oral Sepsis,' respectively. At a meeting of the Duval County Medical Society in Jacksonville November 5, speakers were Drs Samuel R. Norris on "Toxemias of Pregnancy—Case Histories with Autopsies" and Charles B Mabry, 'Use of Unpadded Plaster in the Treatment of Fractures.' Both speakers were from Jacksonville.—Dr Edwin C Swift, Jacksonville, was named president of the Florida East Coast Medical Association November 2. The next annual meeting will be held in Fort Pierce.—Dr Mathew Jay Flipse, Miami, addressed the Palm Beach County Medical Society, October 25, on heart disease.

ILLINOIS

Personal—Mr Homer J Byrd Arlington Heights, has recently been appointed superintendent of registration of the state department of registration and examination.

Dramatized Broadcasts—The Illinois Department of Health began a new series of dramatized broadcasts over Station WCBS in Springfield, December 2. The programs will be presented on Monday and Friday afternoons, portraying in the form of playlets the health adventures and experiences of the Hunter family, who live in the imaginary village of Utopia.

Society News—Dr Anton J Carlson Chicago, addressed a public meeting in Canton, November 25, on pneumonia, the session was sponsored by the Fulton County Medical Society.—At a meeting of the DuPage County Medical Society in Downers Grove, November 20, Dr Harry E Mock, Chicago, discussed treatment of skull fracture.—Dr Leo K Campbell, Chicago addressed the Will-Grundy County Medical Society, November 27, on 'Diagnosis and Management of Diabetes Mellitus.' The society was addressed by Dr Maurice L. Blatt Chicago, December 4, on 'Neuromuscular Diseases in Childhood.'—At a meeting of the Peoria City Medical Society, December 3, Dr Arthur Sprenger, Peoria, discussed 'Recent Observations on the Etiology and Treatment of Urolithiasis.' Dr Leon M Bogart, Flint, Mich, spoke November 19, on 'Abdominal Adhesions.'—At a meeting of the Henry County Medical Society in Kewanee November 7, speakers were Drs Nathan S Davis III and Robert O Ritter,

Chicago, who discussed coronary arteriosclerosis and fractures of the extremities, respectively.—The Mercer County Academy of Medicine was recently organized, meetings will be held twice each month, it was reported.

Chicago

Cooperative Study of Maternal Mortality—Seventy-six hospitals cooperating in a study of maternal mortality in Chicago reported 270 maternal deaths in 1934. Of 38,139 mothers delivered in the hospitals operative intervention was used for 7,765. There were 2,059 abortions reported and 248 ectopic pregnancies. This work is being sponsored by the maternal welfare committee of the Chicago Gynecological Society. The committee is made up of sixty-eight physicians, who represent the seventy-six hospitals in the city doing obstetric work. It is hoped to continue the study until data have been accumulated on 1,000 cases. More than 600 cases have already been studied (THE JOURNAL, August 10, p. 441).

Society News—Dr Chester C Guy, among others, addressed the Chicago Pathological Society, November 11, on "Tumors of the Breast in Children."—Speakers before the Chicago Roentgen Society November 14, included Dr Bernard H. Nichols, Cleveland, on "Roentgenology in the Diagnosis of Obstructive Lesions of the Ureters."—Dr Henry C Sweeney discussed "Recent Trends in the Approach to Study of Silicosis" before the Chicago Tuberculosis Society, November 15.—At a meeting of the Chicago Ophthalmological Society, November 18 speakers included Dr Philip D O'Connor on "Correction of Cicatricial Ectropion by the Detached Skin Graft."—Dr Ben Z Rappaport addressed the Chicago Society of Allergy, November 18 on "Treatment of Patients Highly Sensitive to Pollen."—The Chicago Neurological Society was addressed November 21, among others, by H W Magon, Ph D, and W Kendrick Hare, M S, on "Postural Reactions from Stimulation of the Interior of the Cerebellum."—Dr Harry C Rolnick addressed the Chicago Urological Society, November 21, on "Retrovesical Sarcoma."—The seventy-second annual midwinter meeting of the Chicago Dental Society will be held at the Stevens Hotel, February 17-20.

INDIANA

Outbreak of Scarlet Fever—The occurrence of several cases of scarlet fever in Milan in November prompted the county health officer to order the schools in the city closed for several days newspapers reported. An epidemic was also reported in Rensselaer, but reports, November 21, indicated it to be under control.

Gifts to Museum—A collection of surgical instruments used by the late Dr Joseph L Gilbert, Kendallville, has been given to the Indiana University Medical Museum by his daughters, Mrs Samuel L Shank and Miss Clara Gilbert Indianapolis, according to the state medical journal. Surgical needles, a mahogany case of surgical instruments a rare copy of the second American edition of Gray's Anatomy and a copy of Samuel D Gross's "Lives of Eminent American Physicians and Surgeons of the Nineteenth Century" are included in the collection. Dr Gilbert died in 1928. A tourniquet of the Civil War period has been received from E C Clark of the Akron Surgical House, Indianapolis.

KANSAS

Personal—Dr Riley H Miller Ulysses has been named health officer of Grant County.—Dr John P Kaster, Topeka, chief surgeon of the Atchison, Topeka and Santa Fe Railway system, was guest of honor at a banquet given recently in Topeka by the Santa Fe medical and surgical staff, in recognition of his completion of fifty years as a member of the staff.

Society News—The Sedgwick County Medical Society was addressed, December 3, by Drs Frances H Schiltz and William P Callahan, Wichita, on "Present-Day Status of Liver Function Tests" and Surgical Treatment of Liver and Gall bladder Diseases, respectively. Dr Richard L Sutton, Kansas City, Mo., will address the annual meeting of the society and the woman's auxiliary, December 17, his talk will be entitled 'Snapshots of the South Seas'.

Data on Sickness Insurance—The Kansas State Medical Society has prepared a publication dealing with sickness insurance and state medicine to be used by high school and college students in preparing arguments for the debates on state medicine being held throughout the country. This material supplements that which is being sent to high school and college students from the Bureau of Medical Economics of the American Medical Association.

LOUISIANA

Annual Renewal Due January 1—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually, on or before January 1, by the secretary-treasurer of the state board of medical examiners and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

Health at New Orleans—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended November 30 indicate that the highest mortality rate (183) appeared for New Orleans and that the rate for the group of cities as a whole was 111. The mortality rate for New Orleans for the corresponding period last year was 173 and for the group of cities as a whole, 109. The annual rate for eighty-six cities for the forty-eight weeks of 1935 was 113 and the same rate appears for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly rates, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or have a large Negro population may tend to increase the death rate.

MASSACHUSETTS

Dr. Rosenau Gives Cutter Lecture—Dr. Milton J. Rosenau, Charles Wilder professor of preventive medicine and hygiene, emeritus, Harvard Medical School, Boston, delivered the Cutter Lecture on Preventive Medicine, December 4 at the medical school. He discussed 'Epidemics'.

Physician Honored—Dr. Fred B. Lund, formerly surgeon-in-chief, Carney Hospital, Boston, was honored by a testimonial dinner at the Harvard Club, November 6. Dr. William E. Browne was toastmaster. The speakers included Drs. John Cunningham Jr., Louis F. Curran, Louis E. Phaneuf, William H. Robey, Irving J. Walker, Archibald McKay Fraser, William R. Morrison, Boston, and Nathaniel S. Hunting, Quincy. Dr. Lund was presented with a ship's wheel mantel clock as a memento of the occasion.

Society News—The South End Medical Club was addressed by Dr. Francis Lowell Burnett, Boston, November 19, on 'New Principles for Normal Nutrition and Health to Cure Disease'.—At a meeting of the New England Ophthalmological Society in Boston, November 12, Dr. Harry C. Messinger, Providence, R. I., discussed 'Tuberculous Sclerosis with Tumor of Optic Nerve' and Dr. Phillips Thygeson, Iowa City, gave a paper entitled 'Etiology of Trachoma, Analysis of Recent Studies'.—Speakers before the Worcester District Medical Society in Grafton, November 13, were Drs. Charles E. Morgan, Somerville, president of the state medical society, Benjamin M. Cohen, Cambridge, 'Repression and Communicability in Catatonic Stupor' and Bardwell H. Flower, Worcester, 'Parenteral Paralyde'.—Dr. Frederick F. Russell, lecturer in preventive medicine and hygiene, Harvard Medical School, discussed 'Recent Studies in Yellow Fever'.—A 'Virus Disease' before the Harvard Medical Society, November 12, in Boston.

MICHIGAN

Personal—Mr. J. A. Bechtel has been appointed acting executive secretary of the Wayne County Medical Society. William J. Burns recently resigned as executive secretary of the society to accept a similar position with the state medical society.—Dr. Frank D. Johnson has resigned as coroner of Genesee County, and Dr. Rudolph W. Streat has been named to succeed him. Both are from Flint.

Pediatric Meeting—The University of Michigan Pediatric and Infectious Disease Society held its annual meeting in Ann Arbor, November 22-23. Speakers included Drs. Williams McKim Marriott, St. Louis on 'Severe Nutritional Diseases in Infancy and Childhood' and Clement A. Smith, Boston, 'Calcified Abdominal Glands in Children'. Dr. Daniel Budson, Detroit, gave the presidential address Friday evening and Dr. Marriott held an open forum on infant feeding.

Psychiatric Parole Clinic—A psychiatric parole clinic has recently been established at Eloise Hospital with Dr. Martin H. Hoffmann in charge. Present plans call for a staff of eight psychiatrists, nine psychiatric social workers and one psychiatric nurse. Under the new system mental patients in county institutions will be examined and classified and the mild ones returned home. An efficient follow-up system will be established to secure constant supervision of these people, and accommodations obtained for those who require hospitalization but are now at large for want of adequate facilities. Dr. Hoff-

mann is secretary of the Wayne County Medical Society and the Detroit Society of Neurology and Psychiatry. He graduated from State University of Iowa College of Medicine.

Society News—Dr. Edward L. Bauer, Philadelphia, discussed 'Athrepsia, Acidosis and Alkalosis in Childhood' before the Calhoun County Medical Society, November 5 in Battle Creek.—Sir Wilfred T. Grenfell, St. Anthony, Newfoundland, addressed the Wayne County Medical Society, Detroit, December 2. He also delivered a public lecture in the Hotel Statler, Detroit, November 29. Dr. Oliver P. Kimball, Cleveland, also spoke before the medical society at its meeting, December 2, on 'Source and Medical Study of Epilepsy'.—Dr. Myron Metzenbaum, Cleveland, addressed the Michigan Triological Society at Grand Rapids, November 21 on 'Reconstruction of the Nasal Septum in Children'.—A symposium on syphilis constituted the program of the West Side Medical Society of Detroit at Eloise, November 6, speakers were Drs. Arthur E. Schiller, Frank W. Hartman and Robert C. Jamieson and Elizabeth M. Yagle, Ph.D.—Dr. Abraham R. Hollender, Chicago, addressed the Detroit Otolaryngological Society, November 20, on 'The Scope of Physical Therapy in Otolaryngology'.

MINNESOTA

Handbook on Sickness Insurance—The Minnesota State Medical Association has prepared a forty-eight-page handbook dealing with the various aspects of sickness insurance and state medicine, supplementing material available from the Bureau of Medical Economics of the American Medical Association. Excerpts from talks, newspapers and current magazines are included, representing the opinions of certain members of the medical profession, clergymen and lay authorities on the subject. The material is copyrighted but may be used by members of the constituent societies of the American Medical Association. Information concerning the handbook may be obtained from the office of the association, 11 West Summit Avenue, St. Paul.

Dinner to Drs. Will and Simons—The Sixth Councilor District Medical Society gave a dinner in St. Cloud, November 21 in honor of Dr. William W. Will, Bertha, president-elect, Minnesota State Medical Association, and Dr. Edwin J. Simons, Ahwah Ching, newly elected councilor of the district. Officers and committee chairmen of the district attended and speakers included Drs. Morris Fishbein, editor of THE JOURNAL, Chicago, Charles B. Wright, Minneapolis, Jay Arthur Myers, Minneapolis, and Sidney A. Slater, Worthington. Drs. Fishbein and Myers and Edward A. Meyerding, St. Paul, secretary of the state medical association, addressed a public health meeting the same evening, sponsored by the Stearns County Public Health Association and the Minnesota Public Health Association.

MISSISSIPPI

Society News—A health education conference for parents and teachers of Pike County was held in McComb, October 25-27. Speakers included Drs. Felix J. Underwood, state health officer, John A. Milne, Jackson, director of the field unit, state board of health, 'Community Organization and Parent Responsibility', Taswell Paul Haney Jr., McComb, health officer of Pike County, 'Development of Uniform Standards for Medical Examination' and Henry C. Ricks, Jackson, 'Practical Measures in Communicable Disease Control'.

A New State Journal—Beginning January 1, the Mississippi State Medical Association will publish its own journal entitled the *Mississippi Doctor*. The state society will share this publication with the Northeast Mississippi Thirteenth County Medical Society, the North Mississippi Medical Society and the Mid-South Postgraduate Medical Assembly. It will be printed in Mississippi with Dr. William H. Anderson, Booneville, as editor. The *New Orleans Medical and Surgical Journal* has for many years been the official journal of the Mississippi State Medical Association. Publication of the new journal was approved at the annual meeting of the society in May.

NEW JERSEY

Program on Automobile Injuries—At a meeting of the Associated Physicians of Montclair and Vicinity, October 25, in Montclair, three speakers from New York discussed automobile injuries. Dr. William Darrach spoke on first aid treatment, Dr. Armitage Whitman on injuries to joints, and Dr. James M. Hitzrot on injuries to soft parts. Papers were discussed by Drs. Toufick Nicola, New York, Leslie C. Love, Montclair, and Richard T. Hobart, Upper Montclair.

Society News—Dr. Thomas H. Russell, New York, addressed the Bergen County Medical Society, Hackensack, November 12, on 'Postoperative Complications and Their Man-

agement," and Dr Leroy A. Wilkes, Trenton, executive secretary of the Medical Society of the State of New Jersey, discussed the organization and functions of the society.—The Society of Surgeons of New Jersey will meet in Jersey City, January 15, and not Atlantic City, as noted in THE JOURNAL, November 9. Clinics will be held at the Jersey City Medical Center in the afternoon and a dinner at the Carteret Club.—A symposium on endocrinology was presented at a meeting of the Middlesex County Medical Society at the State Home for Boys, Jamesburg, November 20, by Drs Edward Rose and Charles Mazer, Philadelphia, Matthew Molitch, Jamesburg, Albert W Pigott, Skillman, and Maximilian A Goldzieher, Brooklyn. Several papers were presented by members of the resident staff of the school.—Dr Leonard G Rowntree, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, November 8, on endocrine therapy.—Drs Louis L Williams Jr of the U S Public Health Service and David L Farley, Philadelphia, addressed the Camden County Medical Society, Camden, November 5 on "Malaria—Its Prevention and Treatment" and "Fever of Undetermined Origin," respectively.

NEW YORK

Appointments at Albany College—Dr Thomas Ordway, dean of Albany Medical College, recently announced the appointment of Dr Harry E Himwich, associate professor of physiology at Yale University School of Medicine, as assistant professor of physiology, succeeding Dr F Stanley Randles, resigned. Joseph L Schwind, PhD, associate professor of anatomy at Georgetown University School of Medicine, Washington, D C, was appointed to that position at Albany, succeeding Donald H Barron, PhD. Dr Barron has resigned to pursue research at Oxford University, England.

Annual Registration Due January 1—Every practitioner of medicine and surgery in New York is required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration, on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives, to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

Graduate Lectures at Rochester—A course of lectures arranged by the Medical Society of the State of New York and the Medical Society of the County of Monroe was given at the Rochester Academy of Medicine, October 21-25. Speakers were the following New York physicians:

Dr Fred W Stewart The Changing Concept of Radiosensitivity of Tumors
Dr Robert T Frank Keeping Up with Endocrinology
Dr Russell L Cecil Chronic Arthritis
Dr Edward M Livingston General Abdominal Surgical Diagnosis
Dr Ralph G Stillman, Laboratory Tests and Methods Their Interpretation into Clinical Terms

New York City

Gifts to Columbia—Among gifts to Columbia University recently announced by the secretary are the following for medical purposes:

General Education Board \$17 000 for the subdepartment of tropical medicine and the child development clinic of the Neurological Institute
W K Kellogg Foundation \$10 000 for study of rheumatic fever
Rockefeller Foundation \$2 500 for research in department of practice of medicine and \$750 for the department of psychiatry
E R Squibb and Sons \$2 250 for fellowship fund in the department of biologic chemistry \$1 000 for fellowship in the department of anatomy
Commonwealth Fund \$1 750 for the normal child development clinic in the Neurological Institute
Hardley Corporation \$1 750 for research in the department of psychiatry
William J Matheson Foundation \$1 125 for the Matheson Encephalitis Fund in the department of bacteriology
Louis D Beaumont Trust \$1 000 for research in the institute of cancer research
Arthur M Lampert \$1 000 for the Louis Wiley Memorial Fund in Neurology

Dr Bowman Director of Psychiatric Division.—Dr Karl M Bowman, chief medical officer of the Boston Psychiatric Hospital, has been appointed director of the psychiatric division of Bellevue Hospital, a position made vacant by the resignation of Dr Menas S Gregory in 1934. Dr Bowman was chosen by competitive examination. A graduate of the University of California School of Medicine, Dr Bowman has recently been assistant professor of psychiatry at Harvard Medical School and assistant professor of clinical psychiatry at Boston University School of Medicine. Dr Gregory has been appointed consulting psychiatrist for Bellevue.

Society News—Drs George P Muller, Philadelphia, Shepard Krech and Frederic W Bancroft presented a symposium on mortality in acute appendicitis at a meeting of the

New York Surgical Society, November 27.—Drs Vernon C Rowland, Cleveland, and Samuel J Goldfarb addressed the National Society for the Advancement of Gastro-Enterology, November 27, on "Continuous Acid Adsorption by Aluminum Hydroxide Cream in the Treatment of Peptic Ulcer"—Dr Walter Bauer, Boston, addressed the Medical Society of the County of Kings, November 19, on arthritis. A portrait of the late Dr Frank D Jennings was presented to the society by the alumni association of St. Catherine's Hospital.

NORTH CAROLINA

New Special Society—The North Carolina Eye, Ear, Nose and Throat Society was organized at a meeting in Greensboro, November 14, with Drs Burton W Fassett, Durham, as president and Casper W Jennings, Greensboro, as secretary. The final action followed tentative organization last spring under the name North Carolina Academy of Ophthalmology and Otolaryngology. At this meeting speakers were Drs William S Jordan, Fayetteville, on "The Responsibility of the Refractionist", Michel M Saliba, Wilson, "A New Theory of Light Perception", Alvin C McCall, Asheville, "Glaucoma", Joseph B Greene, Asheville, "Diagnosis and Treatment of Laryngeal Tuberculosis", Harry C Willis, Wilson, "Nasal Neuralgia", and Fred E Motley, Charlotte, "Mastoidectomy".

Society News—Dr Ralph Rhett Rathbone, Washington, D C, was the chief speaker at a meeting of the North Carolina Radiological Society at Greensboro, October 27, on "Treatment of Sinus Diseases and Miscellaneous Diseases"—Dr Edgar V Allen, Rochester, Minn, addressed the Buncombe County Medical Society, Asheville, November 4, on "Peripheral Vascular Diseases"—Drs Joseph A Elliott, Charlotte, and James D Whaley, Charleston, S C addressed the Catawba Valley Medical Society, Lenoir, recently, on skin diseases and nontuberculous infections of the kidney.—At the October meeting of the Tenth District Medical Society, Tryon, speakers included Drs Paul T McBee, Marion, on "Surgical Treatment of Peptic Ulcers," and Cecil C Swann, Asheville, "Relationship of Sinus Disease and Chronic Chest Conditions Particularly Asthma and Bronchiectasis"—Dr Fred M Patterson, Greensboro, was elected president of the North Carolina Urological Association at the sixth annual meeting in Salisbury in October.—Dr John Shelton Horsley, Richmond, addressed the Guilford County Medical Society, High Point, November 7, on "Modern Trends in Diagnosis and Treatment of Cancer of the Colon." Dr James W Tankersley, Greensboro, presented a paper on "Lesions of the Breast."

NORTH DAKOTA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$5 if a resident of North Dakota, or \$2 if a nonresident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and \$0.50 for each month of default.

PENNSYLVANIA

Society News—Dr William J Fetter, Pittsburgh, addressed the Fayette County Medical Society Uniontown, December 5 on "Bone Conditions Important in Medicine."—Dr Samuel J Kopetzky, New York, will address the Harrisburg Academy of Medicine, December 17, on "Petrosal Suppuration."

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually, on or before January 1, with the board of medical education and licensure in the department of public instruction and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100.

Philadelphia

Advisory Committee on Health Survey—At the request of Surgeon General Hugh S Cumming of the U S Public Health Service, the president of the Philadelphia County Medical Society has appointed an advisory committee for the health survey being made by the service. Members are Drs Francis F Borzell, Edward L Bortz, Francis Ashley Faught, Donald R Ferguson, W Burrill Odenatt and Joseph W Post, and John W Ross, DDS.

Society News—Dr Harris P Mosher, Walter Augustus Lecompte professor of otology and professor of laryngology, Harvard Medical School, Boston, gave the Mutter Lecture,

College of Physicians of Philadelphia, December 4, on "Histology and Pathology of the Esophagus with Clinical Application"—The annual banquet of the Medical Alumni Association of the Medico Chirurgical College was held November 21, with Dr Ralph H Spangler as toastmaster, Dr James Evans Scheehle, Harrisburg, secretary of welfare of Pennsylvania, was a guest of honor Dr Jesse Lynn Mahaffey, commissioner of health of New Jersey, Trenton was elected president—The Philadelphia League for the Hard of Hearing the Germantown Club for the Hard of Hearing and the Speech Reading Club of Philadelphia observed National Hearing Week in October with exhibitions of hearing aids and demonstrations of lip reading—A symposium on peptic ulcer was presented before the Philadelphia County Medical Society, December 11, by Drs Robert A. Kilduffe, Atlantic City, N. J., who discussed laboratory observations, Donald Guthrie, Sayre, surgical aspects Martin E. Rehfuss, medical aspects, and Willis F. Manges, roentgen examinations

TEXAS

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually on or before January 1, with the state board of medical examiners, and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1, his license is suspended.

Specialists' Meetings.—Dr Charles W. Flynn, Dallas, was elected president of the Texas Surgical Society at its semi-annual meeting in Galveston in October. Guest speakers at the meeting were Drs William T. Pride, Memphis Tenn. on "Anesthesia and Analgesia in Operative Gynecology—End Results," and John R. Caulk, St. Louis, "Surgery of the Ureter."—Dr Emil Novak, Baltimore was guest speaker before the Texas Association of Obstetricians and Gynecologists in Fort Worth December 7. He delivered the J. I. Y. Paine address in the afternoon on "Hormones of the Ovary" and spoke at the evening banquet on "Current Problems in Gynecology." Dr Ben Hill Passmore, San Antonio, president of the association delivered his official address, on "The Influence of Prejudice and Superstition in Obstetrics."

Medical Service for Low Income Groups.—Two plans for distribution of medical service to low income groups have been approved by the executive council of the Texas State Medical Association. After a study of numerous plans, a special committee appointed at the last meeting of the association evolved a plan for larger county societies, based on one now in operation in Bexar County. The essential feature of the Bexar County plan is a medical service bureau with a physician as full time executive officer. The functions of the bureau are to study the economic circumstances of the individual patient, classify him as to his ability to pay for medical service and arrange for the installment payment for such service. If he cannot pay anything he may either be cared for by the physician of his choice as a charity patient or he may be sent to a free clinic. A special arrangement is outlined for control of these clinics. They are asked to cooperate with the county society to the extent of employing a competent investigator to check the financial condition of applicants, which is to be reported to the bureau. According to the budget plan, the patient signs an installment note and pays interest on deferred payments. The bureau retains 10 per cent of all moneys collected to defray overhead expenses. The committee also recommends systematic publicity to inform the public of the society's efforts to provide a means for adequate distribution of medical service. A modified version of this set-up is proposed for small county societies with the suggestion that several counties may conveniently combine their economic activities in sparsely settled regions. Dr Edward H. Cary, Dallas was chairman of the special committee that drew up the plans, and members were Drs Samuel E. Thompson, Kerrville, Witten B. Russ, San Antonio, Claude C. Cody, Houston, and Frederick Fink, San Antonio.

WEST VIRGINIA

Society News.—Dr Henry J. John, Cleveland addressed the Ohio County Medical Society, Wheeling, November 8, on "Routine Treatment of Diabetes Mellitus."—Dr Americus J. Kemper, Clarksburg, was elected president of the West Virginia Public Health Association at the annual meeting in Huntington, October 30.—Drs Chesney M. Ramage and Amos H. Stevens, Fairmont, addressed the Central West Virginia Medical Society, Buckhannon, October 26, on cancer and treatment of tetanus respectively.—Dr Walter W. Spelsberg, Clarksburg, addressed the Monongalia County Medical Society, Morgantown, Novem-

ber 5, on "Ear Conditions in General Practice."—Drs Russel Kessel and Vincent T. Churchman Jr. addressed the Kanawha County Medical Society, Charleston, November 12, on "Pelvic Inflammatory Disease" and "The Common Cold," respectively.—Dr Thomas G. Folsom, Huntington, presented a paper on "Progress of Rheumatic Heart Disease" at the November meeting of the Cabell County Medical Society, Huntington.

GENERAL

Bequests and Donations.—The following bequests and donations have recently been announced.

University of Cincinnati College of Medicine, \$2,500 for a research fund in internal medicine from Mrs. Louis N. Stix, \$1,000 for the Gamble Fund in the department of bacteriology from Mrs. Alfred K. Nippert and \$500 for the hepatic research fund in biochemistry from the Union Central Life Insurance Company.

Mount View (Marathon County Tuberculosis Sanatorium), Wausau, Wis., \$50,000 by the will of Mrs. Eva M. Willard.
St. Joseph's Hospital, Paterson, N. J., \$2,000 General and Barnert Memorial hospitals, Paterson, \$1,000 each under the will of William B. Gourley.

Methodist Hospital, Scottsbluff, Neb., \$3,000 by the will of J. T. Ryan, Ogallala.

Stuyvesant Square Hospital now known as the New York Skin and Cancer Hospital unit of the New York Post-Graduate Medical School and Hospital, \$15,000 from the estate of Miss Helen R. Johnson, Bennington, Vt.

Poliomyelitis Funds Allocated.—The balls held on President Roosevelt's birthday, last January 30, raised \$1,071,000 for aid in fighting poliomyelitis, it was recently announced. Seventy per cent of the receipts was turned back to the communities in which they were raised. The remaining 30 per cent was retained by the committee, which had \$241,000 after paying expenses. Of this amount \$110,000 was allocated in grants for research on poliomyelitis to the following institutions under the direction of the investigators indicated: Harvard University, Boston, Dr. William Lloyd Aycock, Long Island College of Medicine, Brooklyn, Dr. Sidney D. Kramer, New York University, Dr. William H. Park, University of Chicago, Dr. Paul H. Harmon, University of Pennsylvania, Philadelphia, Dr. Joseph Stokes Jr., Stanford University, Dr. Edwin W. Schultz, University of California, Hooper Foundation, San Francisco, Karl F. Meyer, Ph.D., University of Southern California, Los Angeles, John F. Kessel, Ph.D., Western Reserve University, Cleveland, Dr. John A. Toomey and Yale University, New Haven, Conn. Drs. John R. Paul and James D. Trask. The remaining funds will be used for grants to other projects or further grants to the same projects, in accordance with recommendations of an advisory committee consisting of Drs. George W. McCoy of the U. S. Public Health Service, Washington, D. C., Max M. Peet, Ann Arbor, Mich., and Donald B. Armstrong of the Metropolitan Life Insurance Company, New York. No receipts were given to the Warm Springs Foundation, Warm Springs, Ga., this year. All last year's funds went to the Georgia institution.

Society News.—The Southeastern branch society of the American Urological Association held its second annual meeting in Nashville, Tenn., December 6-7. Among speakers were Drs. Burnett W. Wright, Los Angeles, on "Urinary Complication in an Epidemic of Poliomyelitis," Hugh Cabot, Rochester, Minn., "Methods of Diverting the Urine Above the Level of the Bladder," George G. Smith, Boston, "Total Prostatectomy for Cancer of the Prostate," and Thomas J. Kerwin, New York. "Present Value of Electrical Methods in the Treatment of Certain Urologic Conditions."—Officers elected at the annual meeting of the American Academy of Tropical Medicine in St. Louis, November 20-21, are Drs. Richard P. Strong, Boston, president, Wilbur A. Sawyer, New York, vice president, and Ernest Carroll Faust, Ph.D., New Orleans, secretary. At this meeting the American Foundation for Tropical Medicine was organized, with Dr. Earl B. McKinley, Washington, D. C., as executive secretary.—The seventh annual open meeting of the American Society for the Study of Arthritis was held in New York, December 12, at the New York Academy of Medicine. Papers were presented by Drs. Reginald Burbank, New York, on "Treatments in Arthritis," Loring T. Swaim, Boston, "Prevention of Deformities in Arthritis," and Martin E. Rehfuss, Philadelphia, "Experimental Arthritis and the Treatment of That Disease from the Gastro-Enterological Viewpoint."—The Eastern Conference of Radiologists will be held in Baltimore, January 31-February 1, with headquarters at the Lord Baltimore Hotel. Further information about the conference may be obtained from Dr. Charles A. Waters, 1100 North Charles Street, Baltimore.—Dr. Frederick M. Hodges, Richmond, Va., was elected president of the Southern Medical Association at the annual meeting in St. Louis, November 20, and Drs. Quitman U. Newell, St. Louis, and Joseph E. Knighton, Shreveport, La., vice presidents. Baltimore will be the meeting place in 1936.

LONDON

(From Our Regular Correspondent)

Nov 16, 1935

Accident-Proneness

In an address at the Insurance Institute of London, Mr Eric Farmer, reader in industrial psychology at Cambridge University, said that statistical research showed that in any group of individuals exposed to similar risks the majority of the accidents involved a small number and that accident-proneness was a relatively stable individual characteristic, which manifested itself whenever the opportunity was given. Accident-proneness was now recognized as one of the chief causes of accident. How were the accident prone to be detected so that they may avoid being a danger to themselves and to others? One way was by psychologic and other tests, which measured the qualities involved in accident-proneness, so that it was possible to predict which people were most likely to be involved in accidents. An alternative method was to see whether the knowledge gained by statistical means concerning the accident prone could be given practical effect. To judge in any particular case whether the number of previous accidents was a clear indication of accident-proneness, it was necessary to know by how much that number exceeded the average of the group of drivers to which the individual belonged. If the acquisition of this knowledge proved possible and the results confirmed those already obtained, some means might be devised of preventing the small number of people who are found to be highly accident prone from driving. An effective inquiry would require the cooperation of the government and the insurers. Valuable knowledge might be collected concerning those involved in road accidents if for a period of, say, five years every motorist when applying for a license should be required to produce a certificate from his insurers giving the type of policy that he held, the period of holding and the claims made.

The Myth of Race

A book entitled "We Europeans. A Survey of Racial Problems," by Julian S Huxley, D Sc, secretary of the Zoological Society, A C Haddon, FRS, Sc.D, formerly reader in Ethnology, University of Cambridge, and A M Carr-Saunders, professor of social science in the University of Liverpool, has just been published. Dr Haddon is a leading British anthropologist, Dr Julian Huxley, the grandson of the famous zoologist, is a foremost exponent of the modern doctrine of heredity, and Professor Carr-Saunders is well known as a writer on social and statistical subjects. The authors discuss the principles of human heredity, the bases of ethnic classification, and the main ethnic groups of Europe and Europe overseas. At this time it is interesting to read the latest views of leading British experts. They use the term "ethnic group" instead of "race," as they hold that race in the current conception does not exist in Europe. There are different physical types of man, but crossing has always been widespread and therefore no such thing as a pure race exists. A common popular fallacy is to regard a nation as a race. The unity that underlies the conception of 'nation' is cultural, not racial, and every nation is composed of many physical types. With them are found numerous intermediate types and some widely aberrant types. The intermediate types are not due to blending of discrete characters but to mendelian recombinations. Thus in Devon and Cornwall are seen individuals combining light eyes with dark hair, characters derived from the Saxon type on one side of the border with the British type on the other. However, in reviewing this book Sir Arthur Keith differs somewhat with the authors on the question of race. He says "Races as the zoologist

knows them, have disappeared from Europe, civilization has broken them up and there has come into being, to take their places, a multitude of nationalities. Each nation represents an evolutionary unit—an incipient race. If frontiers could be fixed and national aloofness maintained over many thousands of years, races distinctive in a physical sense would emerge." But Keith's view is supplementary rather than contradictory to the authors' teaching. Moreover, it is known that before the dawn of history the crossing of racial types took place and that nowhere in the historical period has the "national aloofness" for thousands of years, postulated by Keith, been maintained. Of the United States, Keith says "The people there have been recruited from all the countries and races of Europe. Yet in mind they have become 100 per cent American. And if their national spirit and frontiers hold for some 5,000 years they will become 100 per cent American in body too."

Examining the claims for what is called "the Nordic race," the authors point out that the fundamental discoveries of civilization are the art of writing, agriculture, the wheel and building in stone. All these originated in the Near East, among peoples who by no stretch of imagination can be called Nordic. In the classical period Aristotle gave reasons why the Nordic barbarians as well as the Asiatic peoples were incapable of rising to the level of the Greeks. The northern peoples, he said, though endowed with plenty of spirit, are wanting in intelligence and skill, while the reverse held for the Asiatics. But the Greeks were endowed with both sets of qualities.

The Nordic myth in Germany is also exposed. The Germans are found to be a mixture of the Nordic and Eurasiatic (Alpine) races, of which the latter type is now predominant. The view that Germany owes her achievements to the Aryan or Nordic elements is also shown to be wrong. The Nordic type is tall, fair and long headed. But, as Weidenreich has shown the greatest Germans, including Beethoven, Kant, Schiller, Leibnitz and Goethe, were all moderately or extremely round headed (cephalic indexes from 84 to 92). In a recent book the national 1st German anthropologist Kossina is in such difficulties that he has to abandon the racial conception and say that "Nordic souls may often be combined with un Nordic bodies." The authors conclude that racialism is a dangerous myth—a cloak for selfish aims, which in their unclad nakedness would look ugly enough.

Voluntary Euthanasia

The formation of the Voluntary Euthanasia Legalization Society has been described in previous letters. Further particulars can now be given as to the bill allowing sufferers from painful and incurable disease to anticipate death. The procedure laid down is as follows: 1 The person desiring to receive euthanasia must be not less than 21 years of age and must be suffering from a disease involving severe pain and of an incurable and fatal character. 2 He must make an application in writing on a special form and must sign it in the presence of two witnesses, one of whom must be an official witness—a magistrate, lawyer, physician or minister of religion. 3 Before applying, the patient must have consulted his nearest relative and set his affairs in order. 4 The application must be sent to a euthanasia referee (to be appointed by the minister of health) accompanied by medical certificates on special forms. One of these certificates must be signed by the physician in attendance on the patient and the other by a physician having certain qualifications or status to be prescribed by the minister of health. 5 The euthanasia referee on receiving the application and before granting permission for euthanasia must satisfy himself by a personal interview with the patient and otherwise that the requisite conditions have been fulfilled and that the patient understands the nature and purpose of the application. 6 Permission to receive euthanasia shall not operate until the expiration of seven days from the date when the euthanasia referee sends the permit to the patient. The referee shall, on

sending the permit, notify the nearest relative that permission has been granted. 7 Within three days of receiving such notice the nearest relative may appeal to a court on the ground that one or more of the requisite conditions have not been fulfilled, and the court may cancel the permit. 8 Euthanasia shall not be administered by other than a physician named in the permit and shall be administered in the presence of one of the official witnesses.

The consultative medical council of the society is an influential body composed of leaders of the medical profession. The president is Lord Moynihan and the vice presidents are Sir Humphry Rolleston and Sir W. Arbuthnot Lane. The moving spirit is the secretary, Dr. Killick Millard, who was formerly a health officer and published in 1931 in *Public Health* an article entitled "Euthanasia—A Plea for the Legalization of Voluntary Euthanasia."

PARIS

(From Our Regular Correspondent)

Nov 1, 1935

The French Surgical Congress

The second subject chosen for general discussion at the meeting of the forty-fourth French Surgical Congress was "Fractures of the Os Calcis." An exhaustive review of this question was given by Paire and Boppe. Fractures involving the articular surfaces are the most serious from the standpoint of prognosis. They usually mean an invalidity of five or six months and, even when consolidation has taken place, there is much functional disability, the pain on walking often persisting for two years, as the result of a chronic subastragalar arthritis. The severity of the fracture and that of its sequelae are not at all in direct relation to each other. The anatomic reduction of a fracture of the os calcis is very difficult. One should never wait longer than a week to attempt reduction by non-operative or operative methods. Every effort must be made to maintain the reduction either by the instrumental (nail) method of Böhler or by noninstrumental extension applied direct to the greater tuberosity.

Paire and Boppe have observed twenty cases treated by the nail method at Böhler's clinic in Vienna during 1933-1934 and followed up at intervals of from six months to two years after the injury. Aside from a few cases in which horizontal or vertical impaction had taken place, perfect anatomic reduction followed Böhler's first (nail) method. From the functional standpoint the results were not above criticism. Aside from a rarefying osteitis, which persisted for five or six months, the patients were unable to walk well until after about the same period. Any movement of the astragalocalcaneal joint is followed by sharp pain and this continues for about a year after the injury, but ankylosis of the joint between the astragalus and the os calcis persists in 70 per cent of the cases.

Leriche has advocated immediate operative reduction followed by fixation, but Paire and Boppe believe that one should be very conservative in this direction because too many cases have been observed in which a 40 to 50 per cent invalidity resulted because of poor technic.

Operative and nonoperative methods of reduction are a step forward in the treatment of these difficult fractures but they still need to be evaluated. Böhler has had better results than have the advocates of operative reduction but the latter is only of comparatively recent origin. Fixation by mechanical means is preferable to bone grafts if operation is decided on.

In the discussion, Böhler of Vienna showed in a film the various steps of his technic. He has treated 200 cases, and in 88 per cent of these no functional disability has resulted.

Jimeno Vidal of Barcelona, basing his opinion on a large number of cases observed at Böhler's clinic and on fifty personal observations at Barcelona maintained that the orthopedic method was far better than open reduction.

Herman of Antwerp endorsed this point of view. The scar following operation remains painful for such a long time that it causes disability in a certain number of cases, as serious as in cases in which no treatment at all has been given.

Leriche of Strasbourg prefers open reduction and fixation of the fragments by mechanical means and is opposed to nail extension as advocated by Böhler. He defended the incision on the outer surface followed by temporary division of the peronei tendons. If the latter are carefully sutured, no disturbance of movement of the foot results.

Trueta Raspall of Barcelona, after an experience of forty-three cases, is opposed to the nail extension method of Böhler. Open reduction does not give better results than orthopedic treatment. Lateral compression and extension for twenty-five days followed by immobilization for ten weeks have appeared to him the most rational treatment. Any disability persisting more than a year can be considered as permanent.

Chavannaz of Bordeaux was pessimistic regarding fractures of the os calcis. He has seen a 25 to 30 per cent permanent disability in twenty of twenty-two cases. Inadequate reduction, the type of fracture, the changes in the soft tissues, and allowing the patient to walk too early are the chief causes of poor end results. Modern orthopedic and surgical procedures offer better prospects than the older methods of treatment.

Hamant and Grimaud of Nancy maintained that their results in forty-two cases treated by the older methods were better than is generally believed to be the case, only an average permanent disability of 10 per cent being noted by them. If orthopedic methods do not give a satisfactory result, operative intervention is indicated. Open fractures demand the most careful attention to prevent serious complications.

OPERATIONS ON THE DIAPHRAGM, EXCEPTING PHRENICECTOMY

Menegaux read a paper on the technic and Costantini on the physiologic effects of operations on the diaphragm excepting phrenicectomy. Sauerbruch of Berlin, Harrington of the Mayo Clinic, Truesdale of Fall River, Mass., and Jentzer and Cheridjian of Geneva took part in the discussion.

Menegaux of Paris cited the following conditions as indications for operative intervention: 1 Congenital malformations (retro-xiphoid and esophageal hiatus hernias). 2 Injuries with or without accompanying visceral herniation. Those of the left half do not heal spontaneously as well as those of the right half, which are favored by the presence of the liver and hence can heal without operation. If a visceral hernia exists it should be operated on early. Foreign bodies are more frequently found than it is generally believed. 3 Lesions of the esophageal hiatus (stenosis, cardiospasm, hernias containing a portion of the stomach and one or more coils of small intestine). 4 Eventration (usually observed only on the left half). 5 Tumors (usually secondary). 6 Subphrenic abscess or hepatic cysts.

A preliminary phrenicotomy may be of help because of the relaxed condition of the diaphragm. Pneumothorax is dangerous and seldom indicated. The latter is true of plastic operations on the bony thorax. During the operation, one should avoid traction on the mediastinum and especially on the pericardium. Anesthesia under positive pressure will greatly diminish the shock of pneumothorax. In the after-care, large doses of morphine are indicated, not only for the pain but to decrease the demands of the body for oxygen. After a description of the technic of the different ways of approach to the diaphragm, the following conclusions as to the indications for each method were given:

1 To approach the left half the combined thoraco-abdominal route, beginning with the abdominal which alone may suffice.

2 To approach the esophageal hiatus and adjacent portion of the left half of the diaphragm. Abdominal approach with a bougie in the esophagus so as to avoid opening the lumen.

If the closing of the hernial opening is difficult, it is advisable to combine at once the thoracic and the abdominal routes of approach

3 For the right half, one can employ either the thoracic subpleural transdiaphragmatic or the transpleurodiaphragmatic route. In cases of combined liver and diaphragm injuries, it may also be necessary to perform a laparotomy

Costantini of Algiers maintained in his paper that the abdominal mode of approach to the diaphragm was much less apt to give rise to serious complications than the transthoracic route with its accompanying pneumothorax. Much has been accomplished in decreasing the ill effects of a pneumothorax since the introduction of anesthesia combined with positive pressure, and Costantini made a plea for its use in all operations on the diaphragm. Even under favorable conditions the technic is difficult and one cannot determine in advance which patients will present marked evidence of shock followed by asphyxia and death. As a rule, recurrence after operations for diaphragmatic hernia is rare. A preoperative diagnosis of strangulation of such a hernia is seldom made

In the clinical study (preoperative) of nonstrangulated cases the condition of the respiratory and cardiovascular apparatus, of the endocrine glands and of the kidneys must be carefully evaluated. The radiologic examination should yield information as to the location and dimension of the hernial opening. The speaker agreed with Menegaux that preliminary measures such as phrenicectomy, pneumothorax or thoracoplasty were rarely indicated unless the operator did not have at his disposal an apparatus for establishing positive pressure

The abdominal route is less dangerous, but one may have great difficulty at times in reaching the dome of the left half of the diaphragm. The thoracic route permits direct liberation of the hernial contents and better facilities for closing the opening in the diaphragm, but one is confronted with the danger incident to the pneumothorax, such as sudden displacement of the mediastinum. A simple intercostal incision on the anterolateral aspect of the thorax, usually at the level of the seventh rib, permits access to all parts of the left dome. The combined thoraco-abdominal route is the most convenient, but the question of pneumothorax must be considered. However, this route is not any more dangerous than the thoracic approach alone and it has the advantage of permitting an easier liberation of the hernial contents when adhesions are present. The best incision for the thoraco-abdominal approach is a paramedian one (left) extending to the seventh interspace. The degree of positive pressure should be a little above the normal atmospheric pressure. It should be increased during the initial and final steps of the operation and decreased in the interval. Pleural drainage should be employed only if there were many adhesions and some bleeding. It should be by siphonage, with constant aspiration. Postoperatively morphine must be given in relatively large doses. For closing the opening in the diaphragm non-absorbable suture material is preferable. When the hernial opening is large and difficult to close, a phrenicotomy (either cervical or intrathoracic) will render the diaphragm flaccid and facilitate greatly the closure of the opening

Sauerbruch of Berlin, who opened the discussion, greatly preferred the thoracic mode of approach to the diaphragm. In a large number of hernias (diaphragmatic) operated on by him, there were only five deaths

Harrington of the Mayo Clinic prefers the abdominal route. He employs fascia lata as suture material, reinforced by linen thread. In hernias with large openings, a preliminary phrenicotomy renders closure a relatively easy procedure. In a total of 105 operations on the diaphragm there were ninety-seven herniotomies with seven deaths. There were two recurrences in the ninety successful cases. Following operation, the function of the diaphragm is not modified unless there has been wide destruction of the phrenic nerve or its branches

Truesdale of Fall River reported thirteen herniotomies (all congenital) in children. The mortality was 7.5 per cent. He preferred nitrous oxide-ether as an anesthetic

Health Certificates as a Requirement for Marriage

The federal government has just passed a "law to prevent hereditary taints and thereby safeguard the health of the German people." The government seeks to build up a special form of protection for the family by prohibiting the contraction of marriage in the event that the health of either contracting party is of such a nature as to constitute a medical contraindication. The law makes it compulsory for persons who contemplate marriage to report at the bureau of health having jurisdiction, to undergo a medical examination, on the basis of which, if favorable, a so-called *ehetauglichkeitszeugnis*, or certificate of fitness for marriage, will be issued. In the following cases a certificate will be refused: (1) if either of the contracting parties is affected with a disease that may prove contagious and that awakens the just fear that a marked disturbance of the health of the other party or of offspring may result, (2) if either of the contracting parties, after coming of age, has been placed by the courts under a legal guardian, (3) if either of the contracting parties, although not placed under a legal guardian, is affected with a mental disturbance that makes the proposed marriage appear undesirable from the standpoint of public security, and (4) if either of the contracting parties is affected with a hereditary disease within the purview of the law pertaining to the prevention of offspring with hereditary taints

The sterilization law, to which reference is here made, mentions eight groups of diseases that come within the scope of this law. The list of reasons for prohibiting a contemplated marriage is thus raised to eleven. Worthy of note is the fourth provision, that a person, although sterilized, may not enter into a marriage union if his (or her) condition of health comes within the scope of the sterilization law. The legislator, whose duty it is to promote an increase of the population, will not permit a healthy marital partner to remain childless. The practicability of adding "mental disturbances," as in the third provision (not the mental diseases proper as listed in the sterilization law), to the reasons for prohibition of marriage may be doubtful. By "mental disturbances" is probably meant neuroses, depressions and the like, which in view of the summary examination by the health officer called on to issue the certificate, will present no slight difficulties in the way of a definite diagnosis

If both of the contracting partners are foreigners, or if the prospective husband is a foreigner, the law has no application. On the other hand, a foreign woman who plans to marry a German citizen must subject herself to a medical examination. A marriage performed in a foreign country with the object of avoiding the operation of this law is null and void. The penal code provides that the underhanded contraction of a prohibited marriage through false statements, and even an attempt to contract such a marriage, is punishable with a prison sentence of from three months to five years

The aims of this legislation are set forth in a recent pronouncement of Frick, the federal minister of the interior, to the effect that it will insure that only such marriages may be contracted in Germany as will guarantee a healthy offspring. Generations may come and go, but the German people shall live on forever

The so-called Nuremberg law of Sept. 15, 1935, termed "Schutz des Blutes und der Ehre," also forms a part of the marriage control policies of the present German government

The law states that the lawmakers "permeated with the knowledge that the purity of the German blood is a precondition for the continued existence of the German people, and filled with the inflexible determination to make the German nation secure for all future time," have ordered that marriages in which either contracting party is Jewish and the other party is a citizen of German or kindred blood shall be prohibited, and that marriages entered into in a foreign country with a view to circumvent this law shall be null and void. Extramarital congress between Jews and citizens of German or kindred blood is prohibited.

According to official statistics, the upward numerical trend of marriages has persisted. In 1934 the number of marriages per thousand of population was 11.2, which is higher than in previous years. It was only 7.8 in 1913 and 9.7 in 1933. The increase in marriages in 1934 was not so significant in the rural sections as in the cities. In the communes with more than 100,000 inhabitants the marriages were 12.6 per thousand of population, in communes with from 15,000 to 100,000 inhabitants the number was 11.5, and in the rural communes with less than 15,000 inhabitants only 10.2.

An insight into the marriage policies of the government may be obtained also through a scrutiny of the status of the government aid to young couples desiring to marry. In the first quarter of 1935 the law for the promotion of marriages began to show some favorable results. More loans could be remitted because of living births than there were new loans made, and yet the number of marriages did not decrease. There had been eight living births for about seven marriages promoted by government aid. During the first quarter of 1935 there were 34,650 marriage loans granted and 38,904 marriage loans remitted in part. In the second quarter of 1935, 29,662 marriage loans were granted and in 28,356 cases a certain portion was remitted by reason of living births. Between August 1933 and the end of June 1935, 440,826 marriage loans were made and 220,844 loans were remitted in part, in the German reich.

In this connection statistics on divorces, recently published by the federal bureau of statistics, for the year 1933, may be mentioned. In 1933 a total of 42,485 marriages were dissolved by the courts. In 66 per cent of the cases, violation of marital duties (in 1913, 46.8 per cent) constituted the grounds for divorce. Adultery was the charge in 35.2 per cent of the cases (in 1913, 55 per cent). It is apparent, therefore, that adultery as a cause for divorce has declined considerably since the pre-war period. The number of divorces granted because of mental disease has greatly increased (1913 373, 1933, 706). Of the marriages dissolved by divorce in 1933, ninety-three had been contracted within the twelvemonth, 1,035 more than a year but less than two years, 2,384 more than two years but less than three years, and 3,221 more than three years but less than four years. The most critical time appeared to be between four and five years of married life. During this period 3,533 marriages were dissolved. The number of marriages dissolved between the fifth and sixth years was almost as high as between the fourth and fifth, after that a rapid decline was observable. Nevertheless, more than 2,300 marriages contracted between 1908 and 1912 were dissolved in 1933 while about 2,100 marriages contracted previous to 1908 were dissolved. In connection with the child problem, it is interesting to note that nearly half of the marriages dissolved by divorce were childless.

The Health Record Book

For some time the plan of introducing a health record book that would contain data of regular health examinations and would accompany the bearer throughout life has been under discussion. A beginning has now been made with respect to the members of the "Hitler-Jugend," the large and comprehensive youth organization of the national-socialist party. The health record book was introduced some time ago as an experiment

in a certain district, and the observations of the results were favorable. Now the innovation is to be made compulsory in all the families of the members of the Hitler-Jugend, in order to carry out the plan of securing information as to the health of all units of the German people. The medical supervision in schools for the training of leaders, in labor camps and the like, will be greatly lightened in this manner, since the medical observations will always be available. The health record book will have extraordinary importance in occupational guidance. Every two years a supplementary examination, the results of which will be likewise entered in the health record book, will be made.

Pollitzer's Hundredth Birthday Anniversary

Adam Pollitzer, the founder of scientific otology, who was known to the nineteenth century as the leading otologist of his day, would have been 100 years old a few days ago, if he had lived. The anniversary of his birth was celebrated by all fortunate enough to come in contact with this unusual man. Pollitzer was a representative of an inconspicuous Jewish family in Hungary. He received his training in Vienna, where in 1859 he obtained the doctor's degree in medicine. He studied under Claude Bernard, Helmholtz and Toynbee of London, where he laid the foundations for his masterful researches on the anatomy, pathology and physiology of the auditory organ. He introduced many therapeutic methods for ear disorders, most of which are still in use. He was the main moving force in the creation in 1873 of the first ear clinic in the world, at Vienna, although it was of exceedingly modest dimensions, consisting of two rooms with twenty beds, together with a small laboratory. Nevertheless these small rooms soon became the Mekka of all the otologists of the world, for Pollitzer was an excellent teacher, a man of indefatigable industry and possessed of a very exceptional depth of knowledge, thereby inspiring his more intelligent pupils to undertake most valuable researches. His contributions to the knowledge of the anatomy of the ears, to the pathology of otitis media and of catarrh of the middle ear, and his operative technic of the labyrinth, were milestones in the development of otology. The Pollitzer air douche is still used everywhere, his wall charts illustrating the anatomy of the ear, and his illustrations of the ear drum are still unequalled in beauty and precision. The vast majority of the otologists in Europe were and are his pupils, among whom are men of international reputation. The school and clinic that he founded are still flourishing.

Changes in the Medical Faculty

Prof. Dr. Alfred Fischel, the director of the Institute of Embryology at the University of Vienna, has been placed on the retired list. Born in 1868, he studied in Prague and Vienna, whereupon he devoted himself to experimental pathology and embryology. His textbook on embryology ("Lehrbuch der Entwicklungsgeschichte") is a standard work. The Vienna Institute is indebted to him for its valuable and comprehensive collection of embryologic specimens. Fischel's chief field of research was the origin of monsters.

The Vienna Institute of Legal Medicine has been taken over by Prof. Dr. Fritz Reuter of Graz. He is 59 years of age. After pursuing his studies in Zurich and Vienna he became the head of the department of pathology at the University of Graz, and later he served in a similar capacity in the army. Thereupon his field of activity shifted to Vienna, where he became the assistant of Haberdia. He has published numerous scientific works, two of which, "Forensic Gynecology" and his "Textbook on Legal Medicine," have received widespread recognition.

Professor Dr Carl Sternberg

Another of the most eminent representatives of the renowned Vienna school of physicians has received his final summons. Prof. Dr. Carl Sternberg, the pathologic anatomist, died suddenly, during a trip in a row boat, at the age of 64. He was a native of Vienna and secured all his training in this city. As a young physician he came under the influence of Professor Paltauf, whose position in the field of pathologic anatomy is well established. Sternberg soon became his best collaborator and made so quickly a name for himself that, although scarcely 30, he was appointed privatdozent and served as pathologist of the Vienna Policlinic. In 1906 he accepted a position as anatomic assistant at the large hospital in Brunn, where he remained until 1920. He came, however, every week to Vienna to deliver his lectures. During the war he was the chief pathologist and bacteriologist of the army, and it was owing to his skill and diligence that the wartime epidemics were prevented from spreading in Austria. On returning permanently to Vienna he became prominent as "prosektor" of three large hospitals and general secretary of the Vienna Medical Society. In spite of his manifold professional activities, he found time to write more than 150 scientific treatises. His researches included lymphogranuloma, the lymphatic apparatus and its disorders, the pathology of the intestinal tract (including tumors), and typhoid and cholera. His chief work is his textbook on general pathology and anatomy. He was one of the most active members of the Austrian Cancer Society. He supplied also valuable treatises on "The Bacteriology and Pathologic Anatomy of Paratyphoid" and on "Mixed Infections of the Intestinal Tract."

Tuberculous Arthritis

At a recent session of the Graz Medical Society, Dr. W. Berger and Dr. P. Ludwig reported the results of their research on polyarthritis, in which antituberculosis treatment brought striking improvement. They demonstrated two cases in which very severe joint changes, with complete stiffening of the limbs and helplessness, resulted from articular rheumatism, which had remained resistant to all forms of treatment. Finally, the employment of old tuberculin, autovaccines and natural sunlight restored to a great extent the use of the limbs and brought an increase of weight of about 44 pounds (20 Kg.). By using the Löwenstein method, tubercle bacilli could be demonstrated in the blood of both patients. Two years previously, Löwenstein in Vienna, in collaboration with Reitter, demonstrated tubercle bacilli in blood culture in 68 per cent of 209 cases of "acute articular rheumatism" and in 27 per cent of eighty cases of primary chronic polyarthritis. At the Graz clinic, out of twenty-four cases of chronic polyarthritis, which, according to clinical symptoms, appeared to be undoubtedly of tuberculous origin, tubercle bacilli were demonstrated in the circulation in fourteen. The correctness of the diagnosis was further strengthened by the success that followed the tuberculosis treatment (application of tuberculin, strengthened by autovaccines). Likewise in acute arthritis of the type of articular rheumatism examination of the blood gave positive results even in the cases in which treatment with salicylic acid was successful. Also cases of vegetative endocarditis and of endocarditis lenta peracta were studied. Coronini, Popper and Bodart secured in forty cases of recent vegetative endocarditis forty positive and no negative results, cultures of tubercle bacilli from fresh cadaver blood and heart tissues yielded, in endocarditis peracta, five positive and forty-seven negative results. The two speakers reported also having observed cases of tuberculous endocarditis in which the clinical observations coincided with the examinations of the blood cultures. It seems therefore that a considerable percentage of cases of acute and chronic articular rheumatism not only present clinical evidence of a tuberculous origin but also are associated with tuberculous bacilleemia. On

the other hand, one must not overlook the signs that point to a septic etiology, for in more than 10 per cent of the cases these alone were found in the blood and in the joints. Clinical observations on the two kinds of cases force one to adopt the view that a synergism exists in joint pathology between cocci and tubercle bacilli, furthermore, that there is a clinically non-fungous type of tuberculous polyarthritis, in addition, certain other noninfectious factors play a part—hormonic, constitutional, climatic and thermic factors, and possibly still others.

BUCHAREST*(From Our Regular Correspondent)*

Oct. 23, 1935

The Congress of the National Medical Association

The National Medical Association held its annual congress, September 26-28, in the spacious halls of the association. The attendance superseded all previous records. On account of the miserable economic conditions, physicians cannot afford to go abroad and therefore they satisfy themselves by spending some days in the capital.

Prof. Petre Tomescu, the newly elected president, reviewed the activities of the past year. He regards it as an achievement of the association that with its protestation it warded off revision of those physicians who occupy public offices. The government wanted to reduce the number of state clerks and officials at least 33 per cent for economic reasons. This would have been a disaster to hundreds of medical clerks. The successful intervention of the association against this measure means a great victory. Tomescu attaches great hope to the new medical academy, whose competence is beyond criticism. For the coming year, he set up the following program: 1. The public hygienic organization of the country and the interests of the medical profession demand that a campaign shall be undertaken to overcome the indifference with which the government handles public hygiene problems. 2. Vacant medical positions should be filled. At present hundreds of medical positions in villages are filled by medical students in spite of the great number of unemployed physicians, the reason being that the students offer themselves for much less pay. 3. The abolition of unqualified practitioners should be demanded. All foreign diplomas that have not been notified since the war ended should be revised. 4. A society should be founded to assist impoverished doctors, widows and orphans. One solution of this problem is to make representations to the government to allow a tax stamp of 1 leu (half a cent), to be affixed to every prescription.

The medical congress resolved to request the government to modify certain laws that were adopted lately by the senate. To the law forbidding certain qualified persons from carrying on their profession, the association will propose the addition of the following clause: Physicians, pharmacists and druggists shall be prohibited from practicing their profession except under the jurisdiction of the public health law. The law adopted by the senate does not contain any penalties for practicing quackery, while the public health law has several paragraphs for this purpose. Therefore the association finds it necessary to add these words: "Whoever conducts medical practice contrary to the rules of the public health law commits the crime of quackery and is liable to a penalty of six to twelve months imprisonment and a fine of from 5,000 to 50,000 lei."

The association will demand modification of the law on the falsification of public documents by the insertion of this clause: Any physician who knowingly issues a false medical certificate for use by magistrates or insurance companies commits the crime of issuing a false medical certificate and not, as the law signifies, falsification of a public document, and is liable to imprisonment for from one to six months and a fine of from 1,000 to 2,000 lei.

The chapter on induced abortion needs the following modification. It is not regarded an artificial interruption of normal gestation (1) if the life or health is earnestly threatened, and if this danger cannot be averted by any other way, and if this danger can be eliminated by the interruption of gestation, (2) if one of the parents is insane or suffers from inheritable disease or anomaly and there is a well based suspicion as to the child inheriting this severe bodily or mental disturbance. Impunity is secured only for obstetricians, gynecologists or operative surgeons and only in case the abortion has been induced after a consultation with a specialist in the branch to which the disease pertains. A record has to be made of the discussions carried on at the consultation.

As to professional secrecy, the association suggests the insertion of the following paragraph. An attending physician may be absolved from keeping the secret of his patient in instances specified in the public health law, that is, in all cases in which revealing a secret is conducive to saving the lives or health of patients or communities.

Finally, the congress resolved to demand the insertion of a new paragraph on the baseless defamation of physicians. It is not unusual to blackmail doctors by claiming indemnities for badly treated cases. It frequently occurs that, when patients die after operations, the families of the deceased try to obtain compensation. In some cases doctors prefer to pay a certain amount than to be dragged to court. To prevent these abuses it is desirable that the law embody the following clause suggested by the medical association. Whoever publicly states defamatory things about a physician, referring either to his medical practice or to his private honor, which statements, if true, would involve personal or disciplinary prosecution or public contempt or would injure his professional reputation, commits the crime of "slander against a professional man" and is liable to a penalty of imprisonment ranging from six to twenty-four months and a fine of from 2,000 to 8,000 lei.

BUENOS AIRES

(From Our Regular Correspondent)

Sept. 24, 1935

Transfusion of Preserved Blood

In a previous letter (THE JOURNAL, July 27, p 296) the performance of transfusions of blood made in Bordeaux with blood sent from Buenos Aires by Drs Palazzo and Tenconi was reported. The method and technic for transfusion of preserved blood reported by Drs Palazzo and Tenconi (*Semana méd* 1 766 [March 8] 1934, *Rev sud-am de endocrinol* 18 40 [Jan 15] 1935) have been used by Drs Jeanneney and J Viero of France (*Bull et mem Soc nat de chir* 60 1305 [Dec 15] 1934). The blood, while being taken from the donor, is automatically mixed with sodium citrate and then it is passed through a silk filter before its reinjection. The blood is prepared by suspending 100 cc of centrifugated erythrocytes in 235 cc of a solution prepared with two parts of a 3.8 per cent sodium citrate solution and five parts of either a 10.3 per cent saccharose solution or a 5.4 per cent dextrose solution. Then it is kept in the icebox between 1 and 3 C. The centrifugated plasma is kept by itself. Cultures are made to exclude the presence of bacteria, and the blood groups are determined. Blood thus preserved is ready for transfusion at any time, its use avoids the need of resorting to donors in emergencies, the production of shock is rare, the technic is simple, it is inexpensive and the injections can be made at will with the erythrocytes of the plasma or with mixtures of the two. Drs Palazzo and Tenconi have performed about 395 transfusions during the years 1933-1934. The average time of preservation of the cells used was 76 days. In some cases the cells used had been kept for twenty seven days and the same satisfactory results were obtained.

Economic Difficulties of Hospital Physicians

More than 2,000 physicians give free medical care to the public in the hospitals of Buenos Aires, to which they go daily. As there are no restrictions as to the selection of patients, grave conditions, both for hospitals and for physicians, have originated. The number of patients attending free hospital clinics and dispensaries continually increases, but the hospital incomes do not increase and the means are insufficient to cope with the demands of the public. Some persons, either because they bring letters of recommendation or because they give small donations to the hospitals, are given preferential attention over the poor. The physicians' private practice decreases while their free work in the hospitals increases. Many physicians cannot now make a living, and for this reason the group of hospital physicians agreed to ask a small salary from the hospitals. The Partido Socialista presented a project in which a yearly allowance of 5,000,000 Argentine pesos (about \$1,400,000) can be obtained from the government. The attitude assumed by the physicians has gained publicity through the press and by lectures. The opinions of the physicians are conflicting and, while some believe that it is fair to obtain remuneration for their work, others prefer to have a complete readjustment in the present conditions of the profession, without accepting salaries, a fact that they believe may make the members of the profession subordinate employees in the category of proletarians or place them under the direction of political authorities.

Methylene Blue in Cyanide Poisoning

In THE JOURNAL, August 31, is an editorial which reviews Wendel's article dealing with the action of methylene blue in cyanide poisoning, which the author proved experimentally to be due to the capacity of the stain to form methemoglobin in the blood. The same conclusions were reported in 1933 by Hug (*Rev Soc argent de biol* 9 461 [Oct.] 1933, *Compt rend Soc de biol* 114 947, 1933), who made methemoglobin determinations by means of the Van Slyke gasometric method, after injection of methylene blue. He found that methemoglobin is formed, although in quantities no larger than 17 per cent of the total quantity of hemoglobin in the blood. The weak antidotal action of methylene blue, as compared with that of sodium nitrite, is explained by the slight capacity of the former to form methemoglobin in living animals.

Obituaries

Drs Facundo Largaia, formerly director of the Patronato de la Infancia (a child welfare center) and Ramon Aranguren, formerly director of the Instituto Pasteur antirabico (antirabic center) of the municipality of Buenos Aires, have died.

Marriages

- LESTER L. ANDERSON to Miss Estelle Taylor, both of Stoneville, N C, in Chesterfield, S C, November 11.
CHARLES K. FETTERHOFF, Harrisburg, Pa, to Miss Mary Elizabeth Shue of Mount Union, August 14.
CHARLES H. LACLAIR JR, Uniontown Pa, to Miss Loretta K Mercer of Philadelphia, September 21.
ARTHUR P. KEEGAN, Philadelphia to Miss Mary J Noonan of South Scranton, Pa, September 28.
FRANK HURRON MURRAY, Chester, Pa, to Miss Julia Ralston Young of Swarthmore, September 4.
GEORGE S. MOORE, Hartford City, Ind., to Miss Mary Terhune in Middletown, September 5.
ALFRED CHARLES MOORE to Miss Margaret Wells both of Baltimore, September 21.
OTTO A. MILLER Ashland, Pa, to Miss Helen M Fisher of Reading, September 26.

Deaths

Prof Lafayette Benedict Mendel, Ph D, LL D, member of the Council on Pharmacy and Chemistry of the American Medical Association since 1917 and of the Committee on Foods since its inception, an Associate Fellow of the American Medical Association, died at his home in New Haven, Conn., December 9, after a long illness. Professor Mendel was born in Delhi N Y, in 1872, graduated from Yale in 1891, and received his Ph D in 1893. He continued his studies at Breslau and Freiburg in 1895 and 1896. He became assistant in physiologic chemistry in Yale University in 1892 and professor in 1903. In 1921 he was made Sterling professor. He was a pioneer in the study of nutrition in this country, contributing extensively to the literature in his field and exerting a tremendous influence on scores of men and women who worked and were trained under him and then advanced to distinction in other institutions. Much of his work with proteins vitamins and other nutritional factors was carried out in association with Thomas B Osborne distinguished in the field of chemistry of vegetable proteins. Dr Mendel was appointed to many important lectureships in various universities and medical schools. He received the honorary degree of doctor of science from the University of Michigan in 1913 from Rutgers in 1930 and honorary LL D from Western Reserve University in 1932. He was associate editor of many leading publications in the biochemical field both here and abroad and a member of all the leading organizations in his specialty. For many years he was a prolific contributor on his special topic to the editorial columns of THE JOURNAL. Dr Mendel was awarded in 1934 the Conne medal of the New York Chemists' Club in recognition of his outstanding chemical contribution to medicine. He was also gold medalist of the American Institute of Chemists in 1927. As an educator he was a member of the governing board of the Sheffield Scientific School and of the Graduate School of Yale University of the Russell Sage Institute of Pathology, of the advisory board of the J S Guggenheim Memorial Foundation, and of the Commission on Medical Education. He was author of "Nutrition—The Chemistry of Life Changes in the Food Supply and Their Relation to Nutrition" and of innumerable essays and monographs. During the last two years he was confined to bed and unable to work because of a severe disabling illness. His wife, Alice Friend Mendel, died within the past month.

LAFAYETTE BENEDICT MENDEL
1872-1935

Professor Mendel was widely known for the breadth of his knowledge his grasp of complicated problems in the field of medicine, his clear vision and exceptional common sense in their solution. Educators, industrial representatives and public officials in large numbers constantly sought his advice and counsel. By the warmth of his friendship and his love for humanity he endeared himself to all who knew him.

Herman Morris Adler of Berkeley Calif. Columbia University College of Physicians and Surgeons New York 1901 professor of psychiatry, University of California Medical School, assistant professor of psychiatry, Harvard University Medical School from 1912 to 1917, as well as chief-of-staff at the Boston Psychopathic Hospital, in 1916 made a survey of Cook County Ill, on facilities for the detection and care of mental diseases, under the auspices of the Rockefeller Foundation and the National Committee for Mental Hygiene, in 1917 was appointed state criminologist and director of the Juvenile Psychopathic Institute, Chicago during the war served as a

major in the medical corps of the U S Army, on special duty in disciplinary psychiatry at military prisons, professor of criminology and head of the department of social hygiene, medical jurisprudence and criminology, University of Illinois College of Medicine, Chicago, 1919-1928, adviser to the California Department of Institutions, since 1926 director of the Behavior Research Fund, consultant to the National Committee on Law Observance and Enforcement, member of the Illinois State Medical Society, the Massachusetts Medical Society, the American Neurological Association, the American Psychiatric Association, the New England Society of Psychiatry, the Association for Research in Nervous and Mental Disease, the American Psychopathological Association, the Central Neuropsychiatric Association, the American Orthopsychiatric Association and the American Association of Pathologists and Bacteriologists, author of the section on Medical Science and Criminal Justice in the Criminal Justice Survey of the Cleveland Foundation in 1921, aged 59, died, December 7, in Boston, of pneumonia following an operation.

Samuel Gordon Dabney of Louisville, Ky, University of Virginia Department of Medicine, Charlottesville, 1882, Hospital College of Medicine, Louisville, 1883, professor emeritus of otology, rhinology and laryngology, and for forty five years connected with the University of Louisville School of Medicine, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, on the staffs of the Louisville City Hospital and the Norton Memorial Infirmary, aged 75, died, October 15, of chronic nephritis.

Ralph Vincent Robinson of Pittsburgh, University of Pittsburgh School of Medicine, 1911, member of the American Roentgen Ray Society and the Radiological Society of North America, instructor in roentgenology at his alma mater, served during the World War, on the staffs of the Presbyterian and Children's hospitals and the Falk Clinic, aged 51, died, October 5, of cerebral hemorrhage.

James Edwin Rush of Pittsburgh, University of Pittsburgh School of Medicine, 1920, formerly head of the department and professor of hygiene and public health, University of Kentucky, Lexington, at one time field director of the American Society for the Control of Cancer, on the staff of the Tuberculosis League Hospital, aged 48, died, October 14, of heart disease.

George Merrill Gelser, Rochester, N Y, Cornell University Medical College, New York, 1907, member of the Medical Society of the State of New York, trustee, for many years, and past president of the Rochester Academy of Medicine, on the staff of the Rochester General Hospital, aged 53, died, October 21, of coronary occlusion and arteriosclerosis.

Robert Haller Newman of Knoxville Tenn., University of Louisville (Ky) Medical Department, 1905, past president of the Knox County Medical Society, served during the World War, on the staff of the Knoxville General Hospital, aged 55, died October 13, in the Fort Sanders Hospital, of chronic myocarditis and nephritis.

James Allen Marshall of Pontiac, Ill., Detroit College of Medicine, 1886, past president of the Livingston County Medical Society, for thirty-five years attending surgeon at the Illinois State Reformatory, aged 74, died, November 15, in the Passavant Memorial Hospital, Chicago, of carcinoma of the transverse colon.

Henry De Witt Shankle of Washington C H, Ohio College of Physicians and Surgeons, Baltimore, 1889, member of the Oklahoma State Medical Association, served during the World War formerly connected with the Veterans Administration Facility, aged 68, died, September 26.

Everette Odell Arnold, Corpus Christi, Texas, Baltimore Medical College 1909, veteran of the Spanish American and World wars formerly in the U S Public Health Service and medical examiner of the U S Veterans' Bureau, aged 61, died recently, in a local hospital, of tetanus.

Samuel Milan Kitchen, Nashville, Tenn., Vanderbilt University School of Medicine, Nashville, 1935, intern at the Davidson County Tuberculosis Hospital, aged 24, died, September 1, in the Vanderbilt University Hospital, of pneumonia, metastatic septicemia and osteomyelitis.

LeRoy Delmar Cratty, Wilkesburg, Pa., University of Pittsburgh School of Medicine, 1913, member of the Medical Society of the State of Pennsylvania for many years on the staff of the Western Pennsylvania Hospital, Pittsburgh, aged 45, died, October 26.

Edgar Rand, Huntsville, Ala., Medical College of Alabama Mobile, 1879, member of the Medical Association of the State of Alabama past president and secretary of the Madison County Medical Society, aged 79, died, September 8.

Joseph Perry Standley, St Joseph, Mo, Kentucky School of Medicine, Louisville, 1889, member of the Missouri State Medical Association, aged 66, died, November 8, in the Missouri Methodist Hospital, of a skull fracture received in an automobile accident

Wallace Eugene Miller, Mount Hermon, La, Tulane University of Louisiana Medical Department, New Orleans, 1910, aged 50, died, October 3, in the Elizabeth Sullivan Memorial Hospital, Bogalusa, of diabetes mellitus and carbuncle of the neck

Clarence Whitfield Buckmaster, Yonkers, N Y, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894, city health officer formerly member of the school board, aged 63, died, October 7

William Brink Rosecrans, Brooklyn, Albany (N Y) Medical College, 1901, member of the Medical Society of the State of New York, on the staff of the Wyckoff Heights Hospital, aged 61, died, September 25, of pulmonary embolism

Ferdinand Comfort Sommer, Bloomsburg, Pa, Jefferson Medical College of Philadelphia, 1929, member of the Medical Society of the State of Pennsylvania, aged 30, died, October 15, at the Jefferson Hospital, Philadelphia, of meningitis

Zina A Spendley, Chenango Forks, N Y, Eclectic Medical College of Pennsylvania, Philadelphia, 1869, member of the Medical Society of the State of New York, aged 92, died, October 11, of cerebral embolism and arteriosclerosis

Katharine Stemen Hughes, Kansas City, Kan, College of Physicians and Surgeons, Medical Department Kansas City University, 1896, member of the Kansas Medical Society, aged 73, died, October 23, of sarcoma of the mesentery

Frederick Henry Langhorst, Elgin, Ill, Rush Medical College, Chicago, 1900, fellow of the American College of Surgeons, aged 64, on the staffs of St Joseph's Hospital and Sherman Hospital, where he died, September 27

Harold Victor Mangun, Ackley, Iowa, State University of Iowa College of Medicine, Iowa City, 1925, past president of the Hardin County Medical Society, aged 35, died, September 27, in Iowa Falls, of lobar pneumonia

Walter Geddes Hope, Albuquerque, N M, Jefferson Medical College of Philadelphia, 1886 an Affiliate Fellow of the American Medical Association, aged 75, died, September 22, in Los Angeles, of hypostatic pneumonia

Eugene Holdeman, Elkhart, Ind, Medical College of Indiana, Indianapolis, 1897, member of the Indiana State Medical Association, for many years county coroner, aged 61, died, October 14, of bronchopneumonia

Charles Moore Burrows, Albion, N Y, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889, aged 69, died, October 2, of arteriosclerosis and gangrene of the left foot

Charles Claud Greenfield, Argenta, Ill, St Louis College of Physicians and Surgeons, 1904, member of the Illinois State Medical Society, aged 56, died, September 13, in Decatur, of strangulation of the bowel

Leo DeLance Parry, Easton, Pa., Maryland Medical College, Baltimore, 1912, on the staff of the Warren Hospital, Phillipsburg, N J, and the Easton Hospital, aged 45, died, October 13, of carcinoma

Robert Lee Nance, Bedford, Va, University of Louisville (Ky) School of Medicine, 1933, aged 29 intern at the Boston City Hospital, where he died, October 13 of acute tonsillitis and pulmonary embolus

Allen Benson Clark, Joplin, Mo, Columbus Medical College, 1890, member of the Missouri State Medical Association, city health officer, formerly member of the school board, aged 70, died, September 15

Maurice Buchsbaum, Gary, Ind, Rush Medical College, Chicago, 1905, member of the Indiana State Medical Association, aged 68, died October 24, in the Mount Sinai Hospital, Chicago, of carcinoma

Charles Gustaf Nordin, St Paul, University of Minnesota Medical School, Minneapolis, 1910, aged 50 died, October 9, in the Northern Pacific Beneficial Association Hospital, of carcinoma of the liver

Carey E Wamsley, Newport Ky, Miami Medical College, Cincinnati 1906, on the staff of the Speers Memorial Hospital, Dayton, aged 55, died, September 24, in the Christ Hospital, Cincinnati

John Shepard May, Boston Jefferson Medical College of Philadelphia, 1897, member of the Massachusetts Medical Society, aged 64, died, October 10, in the City Hospital, of coronary sclerosis

John Parker Stoddard, Muskegon, Mich, Bellevue Hospital Medical College, New York, 1867, member of the Michigan State Medical Society, aged 100, died, October 11, of cerebral hemorrhage

William M Hatfield, Mulhall, Okla, State University of Iowa College of Medicine, Iowa City, 1886, for many years president of the Mulhall district school board, aged 77, died, October 16

Robert S Freedman, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York 1895, aged 76, died, November 13, of uremia and acute nephritis

Irvine R Bush, Ardmore, Pa, Jefferson Medical College of Philadelphia, 1883, member of the Medical Society of the State of Pennsylvania, aged 76, died, October 15, of heart disease

Roy Mason Sweeney, Sapulpa, Okla, St Louis College of Physicians and Surgeons, 1907, past president of the Creek County Medical Society, aged 52, died, October 18, of carcinoma

Nat K King, Laredo, Texas, Louisville (Ky) Medical College, 1893, medical officer in charge of the U S Public Health Service, served during the World War, aged 60, died, October 14

Adrian Ramon Bustillo, Tampa, Fla, Universidad de la Habana Facultad de Medicina y Farmacia, Cuba, 1922, on the staff of the Centro Asturiano Hospital, aged 36, died, October 4

Albert William Swearingen, Los Angeles, College of Physicians and Surgeons, Keokuk, Iowa, 1885, Jefferson Medical College of Philadelphia, 1888, aged 75, died, September 27

Andrew Henderson, Powell River, B C, Canada, McGill University Faculty of Medicine, Montreal, Que., Canada, 1880, aged 82, died, September 19 in St Paul's Hospital, Vancouver

John Ralph Sickler, Frankfort, Ind, University of Pennsylvania Department of Medicine, Philadelphia, 1902, aged 58, died, October 14, of cerebral hemorrhage and arteriosclerosis

Hiram Zebulon Frisbie, Elkland, Pa, Jefferson Medical College of Philadelphia, 1894, member of the Medical Society of the State of Pennsylvania, aged 68, died, October 11

James Logan Shiland, Santa Barbara, Calif, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882, aged 78, died, September 15

John Blake White, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1874, aged 85, died, November 4, of heart disease

Charles E Stephenson, Columbia S C, Meharry Medical College, Nashville, Tenn, 1903, aged 60, on the staff of the Good Samaritan Hospital, where he died, October 6

George Tupper Swandale, Kenosha, Wis, Bellevue Hospital Medical College, New York, 1878, aged 80, died, October 9, in the Kenosha Hospital, of intestinal obstruction

William Ross Martin, Brooklyn, Omaha Medical College, 1891, member of the Medical Society of the State of New York, aged 69, died, October 13, of heart disease

William H Newlin, New London, Ind, Eclectic Medical Institute, Cincinnati, 1890, aged 70, died, October 27, of heart disease, arteriosclerosis and prostatic hypertrophy

George Cutler Upham, Biddeford, Maine, Bellevue Hospital Medical College, New York, 1882, member of the Maine Medical Association, aged 78, died, October 13

Eugene Henry Bryan, Penryn, Calif, Hospital College of Medicine, Louisville, Ky, 1894, member of the California Medical Association, aged 67, died, October 8

William H Zorger, Champaign, Ill, College of Physicians and Surgeons, Keokuk, Iowa, 1886 member of the Illinois State Medical Society, aged 75, died, September 22

James Dowlen Jones, Emerson, Iowa, Barnes Medical College, St Louis 1896, aged 68, died September 19, in Kellerton, of bronchopneumonia and leukemia

Milton Edward Beitenman, Cascade, Iowa, Creighton University School of Medicine, Omaha, 1924, aged 39, was killed, October 17, in an automobile accident

Henry Roscoe Lawrence, Atlantic City, N J, Jefferson Medical College of Philadelphia, 1881, also a druggist, aged 78, died, October 15, of coronary disease

Oscar Eugene Wright, Fairview, Ky, University of Tennessee Medical Department, Nashville, 1896, aged 63, died, October 13, of carbolic acid poisoning

Emmett E Irwin, Russellville, Ark., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1908, aged 48, died suddenly, September 29, in Fort Gaines, Ga

OBSERVATION VERSUS MEASUREMENT IN FIRE WALKING

To the Editor —With much interest I have read reports of fire walking by Kuda Bux. This includes the item in the London letter (THE JOURNAL, October 19, p 1282)

Again herein the statement is made "his feet making contact with the burning embers for some five seconds each time." I am enclosing herewith illustrations which support the belief that this statement may have been on the basis of opinion without relation to any accurate method of measurement

For a number of years I have been recording human gait. I have nearly 2,000 records at the present time. Approximately 1,000 of these are of normal individuals, accurately timed in seconds and tenths of seconds carried out to the third decimal. Each person, un instructed as to the rate walked a distance of 50 feet at the average rate of 1.8 steps per second. The weight-bearing time from the contact of the heel with the floor until the great toe left the floor was 0.65 second, for only 0.05 second was the entire plantar surface of the shoe in contact with the floor. These figures reveal the function of the foot through the shoe under normal conditions. Work now in progress with a different type of contact for recording strongly suggests that at this rate of walking there may be no interval of time at which the entire plantar surface of the foot is bearing weight. It is well to hold in mind that all of the foregoing applies to normal individuals walking under normal conditions

Normal gait record drawn from average of fifty records

This is important in relation to the statements of the prevailing conditions under which Kuda Bux walked on fire. It is reasonable to believe that under such influences the heel and longitudinal arch were elevated the feet assuming the position of a toe-dancer or as when one is sprinting. It is not necessarily remarkable, therefore, that the court plaster in the arch of the foot failed to show evidence of having been scorched. On a

basis of all facts mentioned herein, it seems reasonably possible that the position and time interval in which this particular individual brought his feet in contact with the hot embers was not such as to produce evidence of blisters

It should be remembered also that Kuda Bux was highly trained in this particular feat. His reaction was correspondingly suited to prevailing conditions, having been conditionally reflexed by repeated experiences since he was 14 years of age. The fact that two other individuals wholly inexperienced in the

Duration of weight bearing on forefoot midfoot and heel

practice failed to meet the task is not necessarily proof that the result of his experience was entirely the result of faith

That one may not be able to account for the influence of faith in this Kuda Bux demonstration is not of itself justification for denying the possibility. It is evident, however, that attention should be called to the time relationship of the contact of the foot with the burning embers of stated temperature. Until more accurate figures are available than those which have been quoted in THE JOURNAL and elsewhere, it seems pertinent to retain an open mind.

R. PLATO SCHWARTZ, M.D., Rochester, N. Y.

FACTS FROM A GOVERNMENT TRANSIENT CLINIC

To the Editor —This communication is being written after two years work in a federal transient bureau of an industrial center on the Great Lakes. Most of the families come from the West and the South.

I presumed when I started my work that most of the transient families and single girls would be suffering from a neurosis due to economic insecurity. This is not true in the family group. A normal family life minimizes other stress and strain. The single girls, however, show instability, in most cases a neurosis. They come from broken homes in most cases and fail to adjust in any environment. They live alone in furnished rooms and complain of being lonely, but when put in groups or in normal homes they become a source of friction.

Families and individuals from the South show an inadequate knowledge of what to buy in the line of foods. I do not mean any technical knowledge of vitamins or minerals but the common information we all have concerning vegetables, fruits and milk. Two persons developed a neuritis as the result of vitamin B deficiency. They bought corn meal, navy beans and salt pork almost exclusively, although the grocery order was ample to include a normal diet. One mother objected to suggestions, stating that she could not afford anything else. When told that kale and boiling beef would be cheaper and go as far as her selection of food, she confessed knowing nothing about kale turnips and many of our common foods.

An attempt is made to vaccinate all nonvaccinated persons and protect all children from diphtheria and whooping cough. Most persons coming from the Southern states are not vac-

cinated and protest by saying ridiculous things as "You're not going to cup my arm off," showing the lack of general education in many sections

The children as a whole are not undernourished. Out of thirty-two, twenty were underweight according to the Baldwin-Wood charts and twelve normal or overweight. Many of the "normal" children showed poor posture according to the standard that a plumb line drawn from the external auditory meatus should fall through the middle of the shoulder and hip joint. Six of the twenty underweight children attained normal weight when given a quart of milk daily and a cereal high in mineral and vitamin B.

In starting the work I was convinced that living quarters played a great part in keeping a child in good physical condition. This may be true of the adolescent, but I found no correlation between crowded, furnished rooms and poorly nourished children, and comfortable homes and healthy children.

Points brought out by the work are that

1 Persons in family groups as a whole are stable emotionally. The single girls as a group show instability.

2 Persons from the South select a deficient diet, often developing a deficiency disease.

3 Many persons from the Southern and Western states know nothing of immunization. A careful watch should be made to immunize persons as they migrate into large cities.

4 Small children do not seem to react to poor living conditions. Their only requisite is food sufficient in quality and quantity.

MARY FETZER MAZZA, M.D., Cleveland

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

WINTER ITCH

To the Editor—A woman, aged 51, complains of itching of the chest arms and face coming on only in the winter. This has appeared for five or six winters perhaps more. During the summer months she is free from the pruritus. With the onset of cold weather, this itching appears usually toward evening lasting throughout the night. The itching is intense. There are no lesions save excoriations from scratching or rubbing. The patient has artificial dentures, cholecystectomy and appendectomy were performed four and one-half years ago. She was treated for residual gallstones by several physicians, but recently I have been able to avert and ameliorate attacks of pain by use of coronary dilator drugs, antipruritic drugs and lotions are without effect, change of bedclothes, linens and covers are of no avail. Ovarian therapy has not helped. The patient is unable to obtain a restful night during the winter. Please advise as to diagnosis and suggested treatment. Blood chemistry and the icteric index are within normal limits. Kindly omit name in publication.

M D Wisconsin

ANSWER—How often does the patient bathe? How much soap does she use? The simplest explanation of the winter itch is that her skin is too dry from excessive use of soap, lack of perspiration, dry cold air outdoors and dry warm air indoors. She should cease the use of soap except on the face, hands and feet and in the folds of the body. She should use rose water ointment, preferably with 10 per cent boric acid, after each bath before the skin is wholly dry. Baths should not be hot, rather lukewarm, followed if possible by a cool douche.

LEAD POISONING IN TOBACCO CHEWERS

To the Editor—What if any are the harmful effects of chewing tobacco while exposed to the fumes of lead daily without a mask? This is an industrial question asked of me for decision. Will you kindly give me your opinion and references in the literature?

M D New Jersey

ANSWER—This question as interpreted, is whether or not the probability of lead poisoning is increased as a result of tobacco chewing by workers during periods of exposure to lead. So simple a matter as this has led to highly divergent opinions. In nearly every report based on any industrial hygiene survey on lead-using departments or industries, a sentence or

two may be found referable to tobacco chewing. In some reports, definite statements may be found recommending the prohibition of tobacco chewing. In others, equally strong recommendations may encourage tobacco chewing as a commendable preventive measure. The facts are these. In some lead-using trades, such as painting, the fingers may become smeared with lead, which may be transmitted to the mouth with every chew of tobacco, and particularly with shredded tobacco in contrast to plug tobacco, which is now little used. This has led to an unfavorable attitude in painting and similar trades. Advocates of tobacco chewing point out with accuracy that tobacco chewers carefully avoid swallowing saliva and are given to much spitting, thus removing from their mouths some of the lead that may be present as a result of dust or other exposure. Further it is to be recognized that some chewing tobaccos contain lead as a result of lead compounds used as insecticides during the growing stage of tobacco. The amount is not large, but it may be detected in qualitative amounts in many samples. In this particular instance the query points out that the exposure of lead is in the form of fume. This is a special factor which must be considered in addition to the transfer of lead to the mouth by fingers contaminated by lead.

EDEMA OF CONJUNCTIVA

To the Editor—A white man, aged 63, has been a locomotive engineer for the last twenty-five years. In the past four months he has noticed a slight swelling of his eyelids especially in the morning and following a day's work on the railroad driving a locomotive 300 miles. Both eyelids of each eye are involved. The swelling has been receding during the day only to return the next morning. Recently (in the past two weeks) it has persisted throughout the day. There are no other complaints. There is no history of illnesses, operations or allergy. Physical examination is completely negative, except for the palpebral edema. The corneas are clear, the conjunctivae slightly injected. The eyegrounds negative. The nose is clear and the teeth have all been removed. The blood pressure is 140 systolic 93 diastolic. The heart and lungs are normal. The abdomen is normal. The extremities show no edema. Laboratory studies reveal blood urea 13.0 Gm creatinine 1.5 blood sugar 110, red blood cells 4,850,000 white blood cells, 7,500 hemoglobin, 88 per cent differential counts normal. Urinary studies show no albumin, sugar or casts on repeated examinations. I am unable to explain the cause of this local edema. Could it be due to the occupation, with exposure to the wind while driving the locomotive? Could you suggest any further studies or explain the cause of this condition? Any treatment?

JOHN C ULLERY, M.D., Philadelphia.

ANSWER—Edema of the conjunctiva and eyelids may be due to such a variety of causes that a rather careful study of each individual case is a necessity. Among the commoner causes are chronic conjunctivitis, chronic inflammation of the accessory nasal sinuses, trichinosis, mild tenonitis, or meibomianitis. It is possible that, in the case here cited, exposure to the continuous wind while running a locomotive may be the exciting factor. It is suggested that the patient be instructed to wear fairly air-tight goggles, such as are used by airplane pilots when in open cockpit planes, and that a mild nonirritating wash be prescribed.

CARBON MONOXIDE POISONING

To the Editor—Last spring I was called to see several members of one family who were all suffering from dizziness, prostration and faintness. Even the family dog had fainted. Recently gas had been installed for heating purposes and the air was much vitiated by the natural gas used in the heating plant. The degree of the contamination must have been high. Fresh air restored them all. Now there is a suit of damages pending. I have not been able to find satisfactory literature on the subject. What are the pathologic changes in such cases and amount and duration of the injury?

N C IKENYAN, M.D., Charleston, Ill.

ANSWER—There is every indication that the described accident represents carbon monoxide poisoning, unless in fact partial asphyxiation was brought about by accumulation of natural gas to the point at which an oxygen deficiency developed. Natural gas commonly contains only a low concentration of carbon monoxide, although artificial gases may be rich in carbon monoxide. In the absence of carbon monoxide in the gas or as a product of incomplete combustion, the gases making up natural gas are chiefly asphyxial in their action. Carbon monoxide goes further in its harmful action in that much lower concentrations are dangerous and because an actual combination takes place between hemoglobin and the carbon monoxide to the end that, even though oxygen is present in the atmosphere, it may not be taken up or partially may be prevented from being taken up by the presence of carbon monoxide in combination with the hemoglobin. Unless the acute manifestations were severe, and unless sequelae developed within a period of two weeks after the last exposure, it is quite believable that no persistent harm may have been produced. These

patients are prone to develop neuroses, neurasthenic states and insomnia, and occasionally actual psychoses arise. The ultimate outcome of nonfatal gassing from asphyxiants largely depends on the extent of injury to the brain during periods of anoxemia. Minute diffuse hemorrhage often leads to permanent neurologic or psychiatric disturbances. The circumstances described in the query suggest a defective installation or perhaps improper operation. Every effort should be made to ward off the possibility of a recurrence of the accident described. In the event of remaining doubt, tests for the presence of carbon monoxide should be made with some such instrument as the continuous carbon monoxide indicator, one or more of which usually are available in most cities and frequently may be found in state department of health laboratories. Ampule detectors may be purchased at low cost. When one of these ampules (which contain palladium chloride in acetone) is broken and suspended in an area suspected of containing carbon monoxide, its contents will turn black in the presence of that gas. This method is sensitive only to a minimum of 0.05 per cent, which percentage constitutes a distinct hazard. Any one of the following publications will furnish extensive additional data:

Henderson, Yandell and Haggard H W. Noxious Gases. New York: Chemical Catalog Company, 1927.
Carbon Monoxide Poisoning and the Automobile Exhaust. Review of Literature by the Special Subcommittee of the Committee on Public Health Relations of the New York Academy of Medicine. Bulletin of the New York Academy of Medicine, August 1926, pp. 402-440.

SINUSITIS IN CHILDREN

To the Editor.—A boy $5\frac{1}{2}$ years of age, weight 45 pounds (20 Kg), height 46½ inches (142 cm), has a persistent pulse of 100 to 120 during the day and from 76 to 84 while sleeping. No pathologic condition exists in the heart although there is quite an irregularity while sleeping. The temperature varies from 99 to 99.6 F. The weight has been constant for about six months and the appetite has been poor. The child has been active and does not tire easily. About a year ago following an acute nasopharyngeal infection his tonsils and adenoids were removed and there has been a slight elevation of temperature and increased pulse rate since then. There is moderate enlargement of the anterior cervical glands and frequent sneezing especially in the morning with frequent attacks of coryza. Roentgenograms of the chest and sinuses give negative results. Three tuberculin tests (one old tuberculin one Mantoux, and one purified protein derivative) have all been negative. Because of symptoms and what observations have been made this condition has been diagnosed as sinusitis. The child rarely complains of headaches. There is no kidney disturbance and the bowels are normal. The boy is an only child of healthy parents and has had good care. He has had iron, vitamin and malt tonics during the past year and attended kindergarten the last half of the past school year. The school activity was very tiring to him. He has been immunized against scarlet fever and diphtheria and has been vaccinated for smallpox. During the past two years he has had measles, whooping cough and chickenpox. Please advise me on the following points: 1. In the absence of roentgen evidence is one still justified in considering the condition as being due to sinusitis? 2. Would mixed stock vaccines aid in clearing this up? 3. Is a pulse rate of 100 to 120 and a temperature of 99 to 99.6 unusual in children of that age? 4. Is it logical to allow this boy the activity of other children of the same age?

MD, Nebraska

ANSWER.—The paranasal sinuses as a rule are not fully developed until the middle period of childhood. The ethmoid cells are present at birth. The sphenoidal sinus is very small in the first year, and the frontal sinus is not present as a rule before the third year. The maxillary sinus develops at about the same period. The sinuses may become infected as soon as they are developed. The diagnosis of sinusitis should be made on the basis of clinical symptoms and confirmed by the x-rays. In the absence of clinical observations and evidence furnished by the x-rays, the existence of sinusitis is improbable.

2. If the diagnosis of sinusitis cannot be established the use of mixed stock vaccines would not be indicated. There is considerable question in the minds of bacteriologists and clinicians whether mixed stock vaccines are of value even when sinusitis is present.

3. A moderate elevation of temperature and an increase in pulse rate are not uncommon in neuropathic and delicate children, though in every instance one should accept this statement only after a careful and most complete examination in order to exclude infection, organic or endocrine disorder or a functional disturbance that comes from fatigue or overactivity. Many an asthenic child shows a slight elevation of temperature and an increased pulse rate and eventually grows to be normal and robust.

4. The child should be permitted to partake of as much exercise and activity as his strength will allow. When he becomes fatigued he should temporarily desist from activity.

LATENT MALARIA

To the Editor.—A woman aged 40 has suffered for the last ten or twelve years from weakness and severe pains which seem to run through her veins. At times she has what she calls "shakes" when she seems to become cold. I have seen her in only one of these attacks a mild one she said and at that time her temperature was 103 F and she seemed to me to be having a malarial chill. That was four or five months ago and there have been no recurrences. The pains of which she complains come on every few days; in fact, she says that she is rarely comfortable but that the more severe suffering occurs at irregular intervals. The suffering seems to be intense and on one occasion I gave her half a grain of morphine before any substantial relief was obtained. After an attack she is very weak; she has spent at least three fourths of her time for several years in bed. She is fairly well nourished and her appetite and her digestion are good. The blood pressure is around 105 systolic and 65 diastolic. The heart is normal; the temperature usually about 98. The urine is normal. Menstruation is normal. There was some anemia a few months ago but this responded to iron therapy. She has been pregnant three times since this condition began and she says that as well as she can remember she felt well and had no "shakes" during the time she was pregnant. During the five months that I have been attempting to treat her she has had iron and other tonics and responded very well as far as her blood picture is concerned but gained little or no strength. Quinine was given on the supposition that an atypical malaria might be causing the trouble. There have been no more "shakes" and no fever but the pain and weakness have remained unchanged. Mentally the woman seems to be quite well balanced and shows absolutely no evidence of hysteria or other mental illness. Can you give me any suggestion as to etiology and treatment? Because of the fact that she was well when pregnant I have thought of using an extract of pregnancy urine but the cost has been against that; however, if in your opinion such treatment would be logical I will try it.

MD, Colorado

ANSWER.—Most likely, this patient has had latent malaria for many years. The treatment with quinine stopped the chills and fever, but the pain and weakness that have remained may be associated with some malarial infection, which still persists. A careful blood examination should be made to determine the presence of a malarial infection and this should include stained blood smears. If the examination should reveal any evidence of malaria a prolonged, thorough course of quinine should be given, and it would be well to combine this with iron and small doses of arsenic. The patient should take a high caloric, well balanced diet with enough vitamins and she should be encouraged to do some daily gymnastic exercises. Even though the blood examination should not at this time reveal any evidence of malaria, it may still be wise to follow the plan outlined.

PARATHYROID DYSFUNCTION IN PREGNANCY

To the Editor.—Two women aged 26 and 40 complain of 'an achy tightness in the lower limbs coming on about the fourth month of pregnancy and lasting for from three to five months after delivery. This discomfort usually starts in the buttock or calf and extends to the arch of the foot and the toes. It comes on only after sitting or lying still for a while and relief comes only after movement or massage if the limb happens to be cold. Unless something is done the sense of tension becomes so great that the limb jerks involuntarily. There is no history of chorea or rheumatic infection in either patient. Calcium therapy was tried in the case of the younger woman without relief. The older woman has had this through repeated pregnancies which were normal; the younger was a primipara and had slight preeclamptic symptoms during the last two weeks. Can you give me any suggestions as to etiology and therapy?

MD, Colorado

ANSWER.—The symptoms mentioned by the correspondent are too vague to enable any one to make a positive diagnosis. Several conditions might be thought of: an unusual form of tetany, circulatory disturbance due to varicose veins in the pelvis, or faulty circulation in the extremities, neuritis on the basis of vitamin deficiency, some form of essential anemia, a disturbed water balance.

The theory of parathyroid dysfunction seems to cover the situation the best, and treatment along such lines would be indicated.

ATROPINE BEFORE ANESTHESIA—DIVINYL OXIDE

To the Editor.—Could you tell me if the injection of $\frac{1}{2}$ -to grain (0.4 mg) of atropine previous to a chloroform anesthesia is a safeguard against the cardiac syncope that sometimes occurs in this anesthesia? I have heard that it is. Also could you send me information concerning the new obstetric anesthesia recently introduced—divinyl oxide? I should like to know where it may be purchased and its approximate cost and whether it has the disadvantage mentioned in the case of chloroform.

ALBERT T. HUME, MD, Chetok, Wis

ANSWER.—The action of the vagus nerves can be inhibited with atropine if it is given in sufficient dose, it is obvious that whatever benefit the patient derives from atropine is through this particular effect of the drug, and unless the patient has an idiosyncrasy to atropine it is wise to administer it as part of the preliminary medication before chloroform is adminis-

tered. J. T. Gwathmey (Anesthesia, second revised edition, New York and London, Macmillan Company, 1924, pp. 372-273) recommends the use of $\frac{1}{100}$ grain (0.6 mg.) of atropine for adult men or $\frac{1}{160}$ grain (0.4 mg.) for adult women, and morphine as a preliminary to chloroform anesthesia. This is particularly true when surgical anesthesia is to be produced with chloroform, but it is also desirable when only the stage of analgesia is to be produced.

Vinethene is the proprietary name of Merck & Company, Inc., for divinyl oxide. The product has been submitted to the Council but does not stand accepted as yet. The Council published a preliminary report on the product Jan. 6, 1934.

USE OF GONADOTROPIC EXTRACTS AND PROGESTIN IN HABITUAL ABORTION

To the Editor—Among other articles read in *THE JOURNAL* at different times I came across the subject of treatment of habitual abortion by the use of Antuitrin S or follutein. That was in the issue of March 23. I have a patient who has been desirous of having children and has been pregnant four different times. Because of abortions she has been unable to bring the children to term the closest being seven months. She is now again pregnant at seven months, was in my office today and again thinks she is going to have trouble. Can you refer me to any kind of serum to be given that might be more certain than Antuitrin S is known to be, or can you give me some good advice that I might pass on to this would-be mother? I would appreciate any good suggestions of later knowledge you may have.

M. D. North Carolina

ANSWER.—There are no clinical reports capable of proving that the gonadotropic principle of pregnancy urine (of which follutein and Antuitrin-S are commercial preparations) prevents abortion. There is a considerable amount of clinical experience supporting the theory that the corpus luteum helps to preserve pregnancy by preparing the uterine mucosa and inhibiting uterine contractions, but the use of the extracts now on the market has not been uniformly successful—sometimes they seem to hurry abortion. One of the most convincing series of cases was presented by Falls, Lackner and Krohn at the Atlantic City session. These authors recommend the use of commercial preparations containing progesterin (the hormone of the corpus luteum) in threatened and habitual abortion, these may be given a trial. There are many causes of habitual abortion: syphilis, kidney disease, focal infections, hypothyroidism, infantile uterus, avitaminosis and the like. This patient should be kept in bed absolutely, the foot of the bed elevated 10 inches, the bowels moved without straining, progesterin given (as described by Falls, Lackner and Krohn), thyroid given if the basal metabolic rate is low or even if normal, a generous diet containing all the vitamins, and calcium and iron.

HERPES GENITALIS

To the Editor—For the last eight months I have been treating a single woman aged 33 for what I diagnosed as herpes genitalis but after every menstrual flow the condition reappears. She states that there is a burning itching sensation about the vulva, followed in a few hours by the appearance of small discrete red spots which rapidly become vesicles and then crust over and disappear in the course of from seven to ten days. I have tried local and general treatment including topical applications of 40 per cent silver nitrate 5 per cent iodine, gentian violet the actual cautery trinitrophenol suppositories, changing the brand of pads used using no talcum powder general intravenous treatment with neocarsphenamine (three doses), calcium and iron tonics, together with ointment of ammoniated mercury and of zinc oxide, but all to no avail. She has no leukorrhea. She states that she has occasional intercourse. The Wassermann reaction is negative. Smears are negative for gonococci and Trichomonas. Can you suggest anything as a possible diagnosis and treatment, excluding venereal warts and faulty hygiene? Please omit name.

M. D. Ontario

ANSWER.—The patient evidently suffers from herpes genitalis, a most annoying and stubbornly recurrent condition.

Aside from the discovery and removal of the cause, such as genital disorder or diseases of the urinary tract or rectum, the treatment is essentially symptomatic. Occasionally, roentgen therapy is almost specific. Nerve resection merits consideration in severe cases.

STAMMERING

To the Editor—Please give me the best possible information on treatment for stammering as to the necessity of going to a school or whether it could be done through the mail or whether the age would limit the possibility of cure. The patient I have in mind is a man aged 33.

CUTHBERT J. LEAVY, M.D. Freeport, Ill.

ANSWER.—Thirty-three years is a good age, as responsibility and determination are present, although treatment takes longer at that age. If the patient has stammered all his life, it will take anywhere from nine months to two years. Large cities

have specialists in the treatment of stammering. Cleveland shows the best school statistics, as it has practically eliminated adult stammering. Private schools for stammering are often unreliable, sometimes good. Treatment by mail cannot be watched and varied according to the peculiarities of the case.

CONGENITAL DEAFMUTISM

To the Editor—A man now 25 years of age had at birth bilateral supernumerary thumbs. These extra appendages were smaller than the normal thumbs but were complete to the extent that they had the usual joint structures with apparently healthy blood and nerve supplies. The mother of the patient was anxious to have these congenital thumbs removed but the family physician advised against their too early removal, stating that if the operation was performed at too young an age it would cause the patient to be a mute. However, the mother became impatient at the advice of the physician and took her son at the age of 2 years to a nearby medical center. At this time the patient appeared normal in every respect with no pathologic disturbance of any of the cranial nerves. The supernumerary appendages were removed by a surgeon, and from two to three weeks following the operation the patient became a mute. He has not spoken a word since that time, apparently devoid of his speech and hearing faculties. He has been seen by prominent specialists who have given a hopeless prognosis but can offer no explanation as to the etiology of the mutism. All neurologic tests are negative except for the loss of the auditory and speech sensations. There appears to be no organic disease present. All laboratory tests including the Wassermann and Kahn tests are negative. The family history is irrelevant. Evidently the family physician had a definite reason for advising against the operation. I would appreciate greatly an explanation of the etiology and physiology of the case. I might add that the child has been mentally alert at all times and has made good progress intellectually in an institution for mutism. Is there any possible treatment or is the prognosis entirely unfavorable?

M.D., Michigan.

ANSWER.—This patient undoubtedly is a congenital deaf mute and would not have learned to talk unless the cause of the deafness could have been removed early in life. As he was only 2 years old at the time of the operation, it is not likely that he had learned to talk before that time. The family physician probably knew or suspected that the child was abnormal and was afraid that the operation might later be blamed for the failure of development, and events proved his wisdom.

OPERATION FOR UNDESCENDED TESTIS

To the Editor—A man aged 43 has been afflicted with undescended testicles since his birth. They are just above the pubic bone and can be felt. No operation has ever been attempted. Some weeks ago he visited a prominent clinic. What he was told or was not told I do not know. Anyway since visiting the clinic he has been badly scared and nervous, and he worries greatly about his condition. I want the best advice possible as to what if anything, should be done with the patient. Is an operation in order and if so what? What chance is there of making adjustments at this age? Please give definite advice and information. Kindly omit name.

M.D., Kansas.

ANSWER.—The most favorable age to operate on patients with undescended testicles is before the age of puberty. Many patients have been operated on past the age of puberty well on into middle life, with good results. The mobility of the testicle does not indicate the length of the cord. For illustration, a man, aged 34, had one testicle in the peritoneal cavity. This testicle was brought down by operation with little or no difficulty, with a normal result. The question of malignancy has been overexaggerated in the literature. In more than a hundred cases only two were found to be malignant, both patients being in their twenties. The indications for operation are sterility, cosmetic reasons, pain, pain due to trauma, and a malignant condition. There is nothing for the patient to be worried about. An operation would do him no harm and possibly would do him a lot of good. If the patient is sensitive about his appearance or has pain, an operation would be indicated, the gubernaculum technic being used to make the fixation. According to the literature no one can state that the patient when operated on past puberty will be fertile. Fertility has nothing to do with impotence. This patient probably never will be satisfied until an operation is done.

STROPHANTHUS IN CORONARY DISEASE

To the Editor—In your answer to a query concerning the use of strophanthus in coronary disease (*THE JOURNAL*, November 9, p. 1543) you state that the only real indication for drugs of the digitalis group in coronary disease is when auricular fibrillation is present. Another important indication for the use of digitalis in coronary disease is when congestive heart failure is present as manifested by either moist rales at the lung bases, a palpable and tender liver or edema of the extremities. The digitalis group will prove of value in such instances even with heart rhythm perfectly regular.

EMMET F. HORINEZ, M.D., Louisville, Ky.

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Written examination for Group B applicants will be held in various cities throughout the country March 14. Oral examination for Group A and B applicants will be held in Kansas City Mo. May 11-12. Applications for written examination should be filed with the secretary before Jan. 15. Sec. Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, March 28. Applications must be filed not later than February 28. Oral clinical and pathological examination of all candidates will be held in Kansas City Mo. May 11-12. Applications must be received not later than April 1. Sec. Dr. Paul Titus, 1015 Highland Bldg. Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY Kansas City Mo. May 11. Asst. Sec. Dr. Thomas D. Allen, 122 S. Michigan Ave. Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis Jan. 11. Sec. Dr. Fremont A. Chandler, 180 N. Michigan Ave. Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY Kansas City, Mo. May 9. Sec. Dr. W. P. Wherry, 1500 Medical Arts Bldg. Omaha.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York Dec. 30. Sec. Dr. Walter Freeman, 1726 Eye St. N. W. Washington D. C.

ARIZONA Basic Science Tucson Dec. 17. Sec. Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson.

COLORADO Denver, Jan. 7. Sec. Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

DISTRICT OF COLUMBIA Washington Jan. 13-14. Sec. Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg. Washington.

HAWAII Honolulu, Jan. 13-16. Sec. Dr. James A. Morgan, 48 Young Bldg. Honolulu.

ILLINOIS Chicago, Jan. 28-30. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

MINNESOTA Basic Science Minneapolis Jan. 7-8. Sec. Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis.

MEDICAL Minneapolis, Jan. 21-23. Sec. Dr. Julian F. Du Bois, 350 St. Peter St. St. Paul.

NATIONAL BOARD OF MEDICAL EXAMINERS Parts I and II Feb. 12-14. May 6-8. June 22-24 and Sept. 14-16. Part III tentatively scheduled as follows: Chicago, Jan. 7-9 and New York, Jan. 13-15. Ex. Sec. Mr. Everett S. Elwood, 225 S. 15th St. Philadelphia.

NEBRASKA Basic Science Omaha Jan. 7-8. Dir. Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEW YORK Albany Buffalo New York and Syracuse Jan. 27-30. Chief Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg. Albany.

NORTH DAKOTA Grand Forks Jan. 7-10. Sec. Dr. G. M. William, 44 S. 3d St. Grand Forks.

RHODE ISLAND Providence Jan. 23. Dir., Department of Public Health, Dr. Edward A. McLaughlin, 319 State Office Bldg. Providence.

SOUTH DAKOTA Pierre, Jan. 21-22. Dir. Division of Medical Licensure, Dr. Park B. Jenkins, Pierre.

TENNESSEE Memphis, Dec. 18-19. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

WASHINGTON Basic Science Seattle Jan. 9-10. Medical Seattle, Jan. 13-15. Dir. Department of Licenses, Mr. Harry C. Huse, Olympia.

WISCONSIN Basic Science Milwaukee Dec. 21. Sec. Prof. Robert A. Bauer, 3414 W. Wisconsin Ave., Milwaukee. Medical Madison Jan. 14-16. Sec. Dr. Robert E. Flynn, 410 Main St. La Crosse.

Connecticut July Examinations

Dr. Thomas P. Murdock, secretary, Connecticut Medical Examining Board, reports the written examination held at Hartford, July 9-10, 1935. The examination covered 9 subjects and included 70 questions. An average of 75 per cent was required to pass. Thirty candidates were examined, 23 of whom passed and 7 failed. The following schools were represented:

| School | PASSED | Year Grad | Per Cent |
|--|--------|-----------|----------|

Aphasia A Clinical and Psychological Study By Theodore Weisenburg M.D. and Katharine E. McBride Ph.D. Cloth Price \$5 Pp 634 with 28 Illustrations New York Commonwealth Fund London Oxford University Press 1935

Of all the problems of neurology, the problem of understanding the aphasia has been one of the most difficult confronting both the clinician and the researcher. An analysis of the literature reveals that some recent textbooks still closely adhere to the motor-sensory classification, while others follow the lead of Head. Why the technics developed by the clinical psychologist have never previously been applied to this field, where they would be more apt than the purely "physical" approach, is a question that arises in one's mind immediately on realizing the mode of attack of these authors to their problem. The psychologists have developed standardized tests of reading and of speech in all their various divisions. These tests have been used in school systems, but psychologists, not being M.D.'s, have been unequipped to go into the hospital to study aphasia and, having inadequate knowledge of neural anatomy, were unable to approach the problem adequately. The present volume, using Weisenburg's neurologic knowledge and McBride's psychologic technics, does do so. The book naturally begins with a historical introduction demonstrating the development of the theories and ideas about aphasia from the time of Broca to the present. Naturally, the work of Hughlings Jackson, Marie, Head and Goldstein is stressed, but the whole literature is covered in sufficient detail although not completely, so that one may gain a thorough idea of the problems confronting Weisenburg when he undertook this study. The whole field was disordered, for where previously authors had felt that they were on safe grounds in dealing with aphasia, the work of Head confused the whole issue. The authors point out that, in addition, Head devised several tests which are really very useful. The present work makes no attempt to undertake a thorough reclassification of those disorders called aphasia but rather divides them up into three types, the expressive, the receptive and the expressive-receptive types. There is a fourth group, the amnesic. Under each type is a discussion and one or more cases are presented to illustrate the point, and these cases are demonstrated in such a way that one can see the value of psychologic tests of reading and speech and really understand the nature of each individual problem. The tests themselves are discussed in a chapter in the early part of the work and are more fully described in an appendix. All the information physiologically, neurologically and psychologically that would aid in the understanding of the processes involved are described fully in each case. Also given are a number of illustrations showing drawings made by the various patients, as well as some illustrations of hand writing. There are several tables, which illustrate better than description the results. The conclusions which the authors have at the end of the discussions of cases seems convincing and sound, a number of interesting and heretofore unrealized factors are discussed. An example of one of them is the fact that aphasic cases which seemingly are neurologically similar vary greatly one from the other in the results of their psychologic tests. The authors carefully control their study by giving these tests to a group of normal persons and also to a group of nonaphasic neurologic patients and the distinctions that are drawn and the various comparisons that are made are interesting and instructive. Most neurologists and psychologists who are interested in speech correction or analysis cannot afford to be without this book. It is so carefully done and so attention compelling that it might

even prove to be worth its cost to the general practitioner. One may predict that its newness of view and attack may cause a question to arise as to its value in the minds of the older men who are already specializing in this type of work, but it would not be rash to say that it should eventually prove itself to be a solid piece of constructive research.

Onchocerciasis with Special Reference to the Central American Form of the Disease By Richard P. Strong Ph.B. M.D. S.D. Professor of Tropical Medicine Harvard University Medical School Jack H. Sandground D.Sc. Assistant Professor of Tropical Helminthology Harvard University Medical School Joseph C. Bequaert Ph.D. Assistant Professor of Entomology Harvard University Medical School and Miguel Muñoz Ochoa M.D. Parasitologist Salubridad Publica Guatemala. Contributions from the Department of Tropical Medicine and the Institute for Tropical Biology and Medicine No. VI. Cloth Price \$4 Pp 234 with 103 Illustrations Cambridge Harvard University Press 1934.

This is a monograph on the Central American form of onchocerciasis, a helminth infection of man, producing swellings around the adult worm, mainly on the head. It is associated with ocular complications resulting in blindness in extreme cases. Dr. Strong, who investigated the disease in Guatemala in 1931 and 1932, contributes the larger section, containing the epidemiologic and endemologic studies, clinical and pathologic observations, ocular complications, transmission, immunity, microfilaricidal substances, public health aspects, prophylaxis and treatment. Dr. Sandground attacks the knotty problems of the classification of *Onchocerca* and critically analyzes the inadequate literature regarding this human helminth and related worms from the horse, cattle and antelope. He gives complete accounts of the adult male and female *Onchocerca caecutius* from Guatemalan cases. Dr. Bequaert describes the insect vectors of the larval stages or microfilariae, namely, the black flies or Simuliidae, of the area of the disease in Guatemala, with studies of their life cycle, eggs, larval and pupal stages, enemies and parasites, seasonal incidence, biting and feeding habits, duration of life, prevention, protection and control. Dr. Ochoa adds a succinct summary of epidemiologic facts derived from his observations on the disease in Guatemala.

Onchocerciasis is sharply restricted to coffee growing districts at an altitude of from 2,500 to 5,000 feet, but not all plantations are afflicted. It occurs largely among Quiche Indians, who form 95 per cent of the population and contribute 98 per cent of the cases. Absence of the disease on a plantation cannot be traced to environmental factors or to absence of *Simulium*, the insect vector. It may be due merely to absence of infected human beings. This irregularity in distribution and lack of early records of the disease support the hypothesis of relatively recent introduction of the worm but are not conclusive on this point.

Three species of *Simulium*, all living in the larval stages in swiftly flowing mountain streams, may become insect vectors. The adult flies are small, from 1.5 to 3 mm in length, fly by day about settlements and plantations, and suck the blood of man from exposed skin of the face and legs. The adult worms live in the tumors, usually on the head. The larval worms, or microfilariae, live in the fluid of the tumor, in the corium of the skin around the tumor, and also migrate to the cornea, iris, conjunctiva and some other parts of the eye, but not in the blood. The saliva of the biting fly seems to attract the microfilaria, and large numbers of the worms are found in flies after feeding on an infected man. Mosquitoes, which draw blood from deeper levels of the skin, were not found to ingest microfilariae. The larval worms pass through three phases in the muscles and other organs of the fly, and increase in length and activity in the final infective stage. When a fly with the infective stage bites man, the worms escape from the mouth parts of the fly and enter the lesion. In less than a year a tumor, containing adult worms, develops in the skin.

The habits of the natives expose them to bites of the flies. More men are infected than women. Tumors may develop on the children only a few months of age. The compression of the scalp by hat bands and the custom of supporting back loads by a head band may contribute to the location of the tumor of the Central American form of onchocerciasis in the scalp. In comparable African infections the tumors are rarely on the head. The disease occurs also in restricted coffee producing regions in the provinces of Chiapas, Oaxaca and Guerrero in Mexico, where rather heavy infections have been reported. The origin

of the disease, first reported in Guatemala in 1915 and in Mexico in 1926, remains a mystery. The investigations of Dr Sandground reveal no significant differences between the Central American worm *Onchocerca caecutiens* Brumpt and the African *O. volvolus* Leuckart. The insect vectors are different in the two continents and the location of tumors is predominantly but not exclusively different. There is no critical evidence of the introduction into tropical America of the African type of disease by African Negroes. It is possible that differences in the biting habits of the insect vectors in the two continents accounts for the clinical differences in the human host.

This monograph is a fine example of an extensive, comprehensive and critical, cooperative study of epidemiology, endemology, pathology, transmission and therapy of a puzzling obscure and, in some respects, mysterious tropical disease involving man, the black flies, and two diverse stages of a nematode worm, perhaps in two continents, and the consequences of the African slave trade.

The Structure and Composition of Foods. By Andrew L. Winton, Ph.D. and Kate Barber Winton, Ph.D. Volume II. Vegetables, Legumes, Fruits. Cloth. Price \$15. Pp. 904 with 303 illustrations. New York: John Wiley & Sons Inc., London: Chapman & Hall Ltd. 1935.

All persons requiring readily available information on the macroscopic and microscopic structure and chemical composition of vegetables and fruits have been looking forward to the printing of the second volume of this highly useful and practical reference compendium. It is another example of excellence of the contributions of recent years being made by American scientists to the technical literature and is the only one of its kind in the English language. The subject matter is well ordered and simply presented. All varieties of fruits and vegetables, even those practically unknown on the American market and table, are represented. The products are grouped according to botanic families. The section on the potato is illustrative of the scope of the material presented. This includes general information, macroscopic structure, microscopic structure, chemical composition, composition of parts of the tuber, influence of locality on composition, relation of development to composition, influence of methods of culture, fertilizers and degree of maturity, changes during storage, losses on boiling, and discussion of potato proteins, acids, carbohydrates, pectins, glucosides, enzymes and mineral constituents. Products of lesser importance of course are less comprehensively discussed. The data are gleaned from world technical literature. The vitamins are outside the province of the book. The authors have devoted much painstaking effort to the compiling of the vast store of data and information in this valuable volume and greatly enriched the fund of available information on food composition, for which many will be duly grateful.

Mechanics of Normal and Pathological Locomotion in Man. By Arthur Steindler, M.D., F.A.C.S., Professor of Orthopedic Surgery, the State University of Iowa, Iowa City. Cloth. Price \$8. Pp. 424 with illustrations. Springfield, Illinois and Baltimore: Charles C. Thomas, 1935.

This long awaited book is the combination of many years of the hardest type of labor on this and related subjects. It reveals a tremendous amount of allied research and study especially in higher mathematics. The author has even been perfecting himself in a knowledge of calculus. As a student of orthopedic surgery in America, he is of course well recognized. It is anticipated that this book will stimulate interest and further study of this important subject, which at first seems abstract but which in its application is intensely practical. It concerns such conditions as poliomyelitis, arthritis, fractures, dislocations, postural defects and scoliosis. The chapters that are especially good are those on the mechanics of the human gait, the pathomechanics of the gait, the physical properties of bone and the dynamics of muscle action. The chapter entitled "From Ancients to Haller" is a classic. It would be impossible to produce this type of book without the cooperation of an unusual anatomist. This the author had in the late Dr. Prentiss. Much of the discussion is difficult to understand. The line drawings and photographs are fine. The publishers deserve much credit. Many American or English illustrations would have been more easily understood than some of those taken from foreign publications. It is hoped that in the second edition this and other irregularities will be smoothed out. Many illustrations are too

small, and the print requires a magnifying glass. A few illustrations are not very illustrative. There are some duplications: for example, figure 7 ($\lambda \lambda$) is the same as figure 13 ($\lambda \lambda$). Figure 6 ($\lambda \times 15$) is the same as figure 8 ($\lambda \times 14$). Figure 6 ($\lambda \times 14$) is marked "flexors" and it should be "extensors". Figure 1 (λ) is marked McMurray instead of McMurich. The volume is excellently written, is unique in its approach to its subject and should promptly be recognized as the best book in its field.

Man the Unknown. By Alexis Carrel. Cloth. Price \$3.50. Pp. 346. New York & London: Harper & Brothers, 1935.

In this volume we observe Alexis Carrel, philosopher, as he surveys the human being with a background of knowledge of physiology, biology and medicine. His introductory chapters indicate the extent of our knowledge and many of the points at which new research is needed. He then discusses the necessity for understanding man as the greatest of all sciences, and indicates some of the technical difficulties encountered in this study. Here he indicates the position which animal experimentation may occupy in the course of such research. Especial attention is paid to the necessity of work on dogs. From this point Dr. Carrel passes to a consideration of various special functions and of the manner in which these functions are disturbed by disease. He emphasizes particularly the effects of the glands of sex and the part played by the male and female elements in reproduction. Especially significant is a paragraph on the working of the normal body.

The difficulties with the volume from the point of view of the physician begin with the fourth chapter on mental activities. Here Dr. Carrel must depart from established scientific fact and enter into the field of imagination. He accepts the ideas of telepathy and clairvoyance and he analyzes the esthetic, mystical and religious senses. He realizes, however, that mental activities depend also on physical activities and in this chapter provides an exaltation of the testis as a motivating organ, which should give considerable stimulation to the rejuvenationists. In fact, he proceeds in chapter 5 to a discussion of longevity and rejuvenation and he wisely concludes that "added years without health and strength would be a calamity. The number of centenarians," he says, "must not be augmented until we can prevent intellectual and moral decay and also the lingering diseases of old age." The human being will not, he believes, ever vanquish death or physiologic time. Dr. Carrel then considers the adaptive functions of mankind and finally the individual human being and the remaking of man. He recognizes the impossibility of overcoming biologic laws but at the same time emphasizes the desirability of applying the scientific knowledge we now have for greater health and great power.

Here then is a book full of sound thought on many topics but unscientific so far as the author enters into the imaginative field in relationship to processes that are not yet understood. Certainly the book will repay the time spent on it by any thinking man. It is unfortunate, however, that the publisher in choosing a type for the book has selected one so ornamental as to make reading a little difficult.

Clinical Tuberculosis. Edited by Benjamin Goldberg, M.D., F.A.C.P., F.A.P.H.A., Associate Professor of Medicine, University of Illinois College of Medicine. With the collaboration of thirty-three contributors. In two volumes. Cloth. Price \$22. Various pagination with 649 illustrations. Philadelphia: F. A. Davis Company, 1935.

This consists of chapters prepared by a large number of authors and edited by Dr. Goldberg. Almost all phases of the disease are covered from epidemiology, bacteriology, pathology, complications, diagnosis, classification, treatment and prognosis to prevention. The first chapter, by Drolet, on epidemiology, takes into consideration the tuberculosis record for New York, Philadelphia and Boston for 120 years. He illustrates definitely that the mortality has been decreasing for more than fifty years. He calls attention to the fact that until recently in many places the tuberculosis mortality rate was highest during the first year of life but that now the picture has been radically altered. For example, in 1900 in the ten original registration states 350 male infants under 1 year of age died of tuberculosis for every hundred thousand living, but by 1929 the mortality rate for male infants had dropped from 350 to 58.

Among female infants in 1900, 295 died of tuberculosis per hundred thousand living, but in 1929 this figure had dropped to 52, while the rate for young women between 20 and 25 years was 120 per hundred thousand living in 1929. Drolet believes that this marked decrease in infant mortality is due to segregation of open cases of tuberculosis and increased home and sanitary supervision of all members of families with tuberculosis. This chapter contains much valuable information concerning tuberculosis among the various races of people, as well as the effect of occupation and other factors on the disease. The chapter on the pathology of pulmonary tuberculosis, by Jaffe, deals first with the primary form of the disease and finally with the clinical form. Rankes classification is followed. Ornstein and Ulmar have presented excellent chapters on the physical diagnosis and classification of pulmonary tuberculosis, in which a complete description is given of the various abnormal physical signs. These chapters are followed by a rather elaborate discussion of the roentgen examination by Potter. The concluding chapter in the section on diagnosis is written by Goldberg, who discusses the subject of differential diagnosis. The entire subject of therapy from diet, strict bed rest, through collapse therapy, is well presented by a number of authors, including Matson, Coryllos, Hedblom and Mayer. The two volumes are profusely illustrated and contain a large amount of valuable information for all physicians interested in tuberculosis.

Pellagrole Dermatosen an Gelsteskranken mit besonderem Hinblick auf das Vorkommen solcher bei Schizophrenen und mit Beiträgen zur Beleuchtung gewisser ätiologischer und pathogenetischer Verhältnisse bei Dementia praecox und Pellagra. Von Paul J. Reltter Dr. med. Abteilungsarzt am Sct. Hans Hospital II Dänemark und Jakob Jakobsen. Paper. Pp. 125 with 20 illustrations. Copenhagen. Levin & Munksgaard. Leipzig. Georg Thieme. 1935.

This is a clinical study of 955 mental patients in a Denmark asylum, in 182 (19.3 per cent) of whom pellagroid skin lesions were found, mainly of a hyperkeratotic type on the elbows, knees, hands and face. The highest incidence was seen in the encephalitis cases (60 per cent), next in the schizophrenic group (21 per cent) and third (8.6 per cent) in the manic depressive class. Fourteen cases were considered to be true pellagra on account of the association of a severe dermatitis with stomatitis, diarrhea and neurologic symptoms. Other skin disorders, such as acne and rosacea, were frequently found in the dementia praecox group. As controls, 881 criminals in the state prison were investigated to determine the effect of a low vitamin diet on the frequency of skin changes, and only 4.5 per cent were found to have pellagroid dermatoses. Investigations of the gastric contents and blood changes in the dementia praecox group with skin lesions showed the frequent association of hypochlorhydria and achylia with lymphocytosis and eosinophilia. The observations recorded are of interest in showing the frequent occurrence of "pellagroid" dermatoses in mental cases, although nothing new has been added to explain their pathogenesis. Similar observations have been made in this country in the so-called pseudopellagra occurring in alcoholic addicts.

The Patient's Dilemma. A Public Trial of the Medical Profession. By S. A. Tannenbaum M.D. and Paul Maerker Branden. Cloth. Price \$2.50. Pp. 278. New York. Coward McCann Inc. 1935.

The medical author of this book apparently graduated from the College of Physicians and Surgeons, New York, thirty-seven years ago. He is now exposing the hideous truth about the commercial side of the practice of medicine. When he gets all through with his exposure he has done nothing but expose his own ignorance of the situation. Perhaps a better recognition of the true state of affairs would have kept him from such an out-and-out exhibition of bad taste, exaggeration and malice as is represented by this volume.

At the time of this writing the book has already been before the public for some months and it apparently has fallen with a dull and unexciting thud. Apparently the author intended to rouse public wrath and to shake public confidence in the medical profession but has served only to reveal the great confidence that actually exists and the inability of scandal mongers within or without the profession to shake that confidence. It would be, therefore, a work of supererogation to analyze the

volume page by page. One finds the usual criticisms relative to fee splitting and to the abuse of physical therapy apparatus for purposes of income. One finds attention called to the small incomes of a good many doctors and to the large charges occasionally associated with major medical procedures. The book is utterly inadequate in its consideration of present plans for medical practice and in its defense of socialized medicine.

Some Thoughts of a Doctor. By Frederick Parkes Weber M.A. M.D. F.R.C.P. With a preface by Sir W. Langdon Brown M.A., M.D., F.R.C.P. Regius Professor of Physic in the University of Cambridge. Cloth. Price 6s. Pp. 183. London. H. K. Lewis & Co. Ltd., 1935.

These essays, thirty-one in number, range from such subjects as "Nature and God" and "The Rights of Nations" to "The Gambling Spirit" and "Exercise, Work, Rest and Sleep." They represent the meditations of a scholarly physician over various aspects of life and living. The same breadth of information which the author has shown in his medical writing is exemplified in his essays on subjects far removed from medicine. Many of them are reminiscent of Osler's treatises, though they are highly individual and original in thought. While the writer lacks an engaging literary style, the essays are stimulating. The physician will enjoy taking issue or agreeing with the author on the many subjects he has treated provocatively.

A Textbook of Clinical Neurology with an Introduction to the History of Neurology. By Israel S. Wechsler M.D. Professor of Clinical Neurology, Columbia University. New York. Third edition. Cloth. Price \$7. Pp. 826 with 162 illustrations. Philadelphia & London. W. B. Saunders Company. 1935.

This edition appears with minor changes in the text throughout and with the valuable addition of a chapter on the history of neurology. This chapter, although containing a good deal of factual material, does not accomplish its purpose as an addendum to the book at large. It is unfortunate that selected bits of neurologic history are not placed in the various chapters of the diseases to which the history refers. Otherwise the book is essentially like the second edition with a few minor alterations. Dr. Wechsler has had the good judgment to maintain the book in the form and style that created its intense popularity. The book is an excellent and valuable introduction to clinical neurology.

Recent Advances in Diseases of Children. By Wilfred J. Pearson, D.S.O. M.C. D.M. Physician in charge of Children's Department, University College Hospital, London and W. G. Wyllie M.D. F.R.C.P., Physician to Out Patients Hospital for Sick Children, Great Ormond Street, London. Third edition. Cloth. Price \$5. Pp. 666 with 61 illustrations. Philadelphia. P. Blakiston's Son & Co. Inc. 1935.

The authors of this concise treatise have maintained the editorial policy of the previous editions in presenting a connected outline of the diseases in childhood. For the most part many of the chapters have been recast and revised. Those who are familiar with the previous editions will find an apparent similarity, but this is only in form. The authors have sought mainly to formulate principles for solving problems of disease in children. These do not change as often as scientific data, but the reader often benefits by their restatement. The book is unique in its style and manner of presentation, and the physician and student will benefit by its concise correlations. It is not recommended as a textbook in pediatrics but as a complementary volume.

Aids to Ophthalmology. By N. Bishop Harman M.A. M.B. F.R.C.S. Consulting Ophthalmic Surgeon, West London Hospital. Eighth edition. Cloth. Price \$1.25. Pp. 242 with 203 illustrations. Baltimore. William Wood & Co. 1935.

This is a pocket size quiz compend type of book which attempts to cover the anatomy, physiology, diseases, refraction and surgery of the eye, without an attempt to be complete in and of itself. There are many Unusual diseases "are intentionally omitted." There are numerous illustrations and several tables. A chapter on eye conditions in school children is based on 22,000 examinations in London. The diseases and refractive errors of this group are discussed. One chapter deals with the visual requirements for the various governmental and municipal services and industries in Great Britain. The book is concise and is of value when preparing for examinations or reviewing the subject but is too brief to serve as a textbook.

Medicolegal

Malpractice Facial Paralysis and Deafness Following Mastoidectomy—One of the physician-defendants performed a "radical" mastoidectomy on plaintiff. Facial paralysis and deafness in the ear involved resulted. The plaintiff, contending that he had consented only to a "simple" mastoidectomy, sued the defendants for performing an unauthorized operation and for negligence in connection with the operation. The jury returned a verdict for the plaintiff for \$30,000 and, after first rendering judgment on the verdict, the circuit court reversed itself and ordered a new trial. The plaintiff appealed to the Supreme Court of Wisconsin.

If, said the Supreme Court, the radical operation was performed without the consent of the patient, either express or implied, then the operator was guilty of an assault and would be responsible for damages resulting therefrom. The court, however, agreed with the circuit court that the case was ineptly submitted to the jury with the result that there was a lack of findings by the jury on which to base a valid judgment as to the amount of damages resulting from the "radical" operation as distinguished from the "simple" operation. The case should have been submitted in such a form as to exclude from consideration, in assessing damages, the expense, pain and natural or necessary results of the "simple" operation to which the patient concededly submitted. While it may be difficult to draw an exact line between the extent of the "simple" operation and the beginning of the "radical" operation under the circumstances of the case, the assessment of damages must nevertheless be made with that distinction in mind. This error was of sufficient gravity, in the opinion of the court, to warrant the granting of a new trial.

The trial court committed no error in permitting a physician, licensed in Iowa, to testify as an expert witness for the plaintiff. Section 147.14 (2), Wisconsin Statutes, provides, in part:

Practitioners in medicine, surgery or osteopathy licensed in other states may testify as experts in this state when such testimony is necessary to establish the rights of citizens or residents of this state in a judicial proceeding and expert testimony of licensed practitioners of this state sufficient for the purpose is not available.

When a party has shown, said the court, the taking of adequate steps to secure the aid of Wisconsin physicians, and that he has been unable to secure it, he may call as a witness an expert from without the state. It was for the trial court to determine whether or not the plaintiff in this case had in good faith attempted to secure the aid of Wisconsin physicians, and, having so determined, in the absence of a showing of an abuse of discretion, the determination is final. The action of the trial court in granting a new trial was affirmed.—*Paulsen v Gunderson (Wis)*, 260 N W 448

Evidence Exhibition of Injured Knees to Jury—Sylvia Mayson was employed as an entertainer in a cabaret. As a result of a collision between the taxicab in which she was riding and a truck, she sustained injuries and sued the cab company and the owner of the truck. The trial court gave judgment for her and the defendants appealed to the Court of Appeals of Maryland.

At the conclusion of the plaintiff's testimony, and after she had exhibited scars on her face, neck and forehead to the jury, her counsel requested permission to exhibit to the jury the injuries to her knees. Counsel stated that his desire to have his client exhibit her knees was because of her occupation, she having testified that her vocation was that of entertainer, dancer and singer, and that the disfigurement of her knees vitally affected her in this respect. The trial court in acceding to counsel's request, stated that while ordinarily such scars on the knees would not be an element of significance, yet in view of the plaintiff's occupation the evidence was admissible in this case. The admission of this form of evidence, said the Court of Appeals, was entirely in the discretion of the trial court, and there was no impropriety or error in its admission. The plaintiff had testified that she had two "brush burn wounds" on her knees, the scars of which remained. The exhibition of her

knees merely corroborated her oral testimony in this respect. In its ruling, the Court of Appeals cited *Chicago & A R Co v Clausen*, 173 Ill 100, 50 N E 680, a case in which the Supreme Court of Illinois upheld the lower court in permitting a plaintiff to exhibit to the jury a rupture alleged to have been a result of an accident.

Finding no error in the rulings of the trial court, the Court of Appeals affirmed the judgment for the plaintiff.—*Zeller v Mayson (Md)*, 179 A 179, *Rubenstein v Same (Md)*, 179 A 179

Evidence Opinion of Expert Witness Based on the Opinions, Inferences and Conclusions of Other Witnesses—The opinion of an expert witness, said the Court of Appeals of Maryland, however qualified he may be to speak, cannot be predicated, either in whole or in part, on the opinions, inferences and conclusions of other witnesses. A witness who is qualified as an expert, who has heard the entire testimony in the case, and who assumes the truth of it all, may base his opinion on such testimony, where not conflicting, but the opinions of other witnesses may not be incorporated in the question or taken into account in giving his answer.—*Mt Royal Cab Co, Inc v Dolan (Md)*, 179 A 54

Medical Practice Acts Jurisdiction to Reinstate Revoked License in Court Not Board—The plaintiff, a physician, was convicted of violating the Harrison Narcotic Act and sentenced to the penitentiary. While he was so confined, the board of medical examiners revoked his license to practice medicine and the board's action was sustained by the Supreme Court of Iowa. *State v Hanson*, 201 Iowa 579, 207 N W 769. After serving his sentence, the plaintiff returned to Iowa and began anew to practice medicine but was enjoined from continuing to do so. Subsequently, the board of medical examiners, with the consent of the district court, gave him what the court refers to as a "sort of license to practice under" another physician, which license was later withdrawn. On numerous occasions, the plaintiff petitioned the board of examiners to reinstate his license and on May 11, 1933, the board passed a resolution denying the application for reinstatement, contending that a statute, passed after the revocation of the license, transferred from the board to the district court jurisdiction in all matters relating to revocation of licenses. Thereupon the plaintiff instituted the present proceedings to compel the board to issue the license. From a decree by the district court in favor of the plaintiff, the board appealed to the Supreme Court of Iowa.

At the time the plaintiff's license was revoked, said the court, the medical practice act conferred on the board of examiners the right to revoke or suspend a license "for such a time as the board of medical examiners may determine." Subsequent legislation, however, divested the board of this right and conferred it on the district court of the county in which the physician involved resides. Hence, the board correctly in this case concluded it had no jurisdiction to reinstate the plaintiff's license. The district court erred in considering the merits of plaintiff's case. The sole issue was a question of jurisdiction. The decree of the district court was therefore reversed.—*Hanson v State Board of Medical Examiners (Iowa)*, 260 N W 68

Charitable Hospitals Liability for Negligence in the Selection of Servants—The plaintiff filed complaint against the defendant, a charitable hospital, alleging that the hospital was negligent in selecting incompetent and unskilful employees through whose negligent care and treatment she was injured. The trial court dismissed the complaint, and the plaintiff appealed to the Supreme Court of Wisconsin.

The plaintiff contended that the defendant, although it was a charitable institution, must use due care in the selection of its employees to whom it entrusts the care and treatment of its patients, and that this is a nondelegable duty, for the non-performance of which the hospital is responsible. It was conceded that a charitable hospital is not liable for the negligence of its employees. The basis of this rule, said the court, is that these hospitals perform a quasipublic function, akin to

that performed by municipalities in performing governmental functions, and justice and public policy require that the doctrine of respondeat superior shall not be applied. But, said the Supreme Court of Wisconsin, the reason for the rule as applied to the negligent acts of servants applies with equal force whether the negligent act is of a nurse or other employee employed by the hospital, or the negligence of its manager or managing board in selecting the nurse or other employee. The hospital can act only through its agents in selecting its employees. The agent who selects the employee is an agent of the hospital in no different sense than is the employee thus selected. The duties of the two agents are different, but the agency relation is the same, and if the doctrine of respondeat superior does not apply to the acts of one, it should not to the acts of the other. On reason, therefore, if a charitable hospital is exempt from liability for negligent acts of its incompetent employees committed on its patients, it is exempt from liability for negligence of its managing agents in selecting those incompetent employees. Precisely the same reason lies for exemption in both cases and it lies to precisely the same extent. A physician is in many cases the managing agent of a hospital. That such a hospital should be exempt from liability for the tort of its managing agent in himself negligently performing an operation which he was incompetent to perform, and should be liable for the negligence of the same physician in delegating another physician to perform it who was incompetent and negligently performed it, is utterly irreconcilable, the court concluded. The judgment of the trial court, dismissing the complaint, was affirmed.—*Schunacher v Evangelical Deaconess Soc of Wisconsin (Wis)*, 260 N W 476

Malpractice Tonsillectomy Performed on Intoxicated Patient—The defendants removed the tonsils of plaintiff's husband under a general anesthetic. Three hours later he died. Attributing the death to the fact that the defendants operated on the patient when he was intoxicated, the plaintiff sued. The trial court gave judgment for the defendants and the plaintiff sought a reversal in the court of civil appeals of Texas.

The expert testimony in this case, said the court, does not show that any negligence on defendants' part was the proximate cause of the patient's death. During a period of two days the patient consumed approximately 7 pints of intoxicating liquor. About 7 o'clock in the evening of the second day, after eating a large meal, he went to a hospital for the purpose of having his tonsils removed by the defendants. He was operated on about 8 o'clock that evening, the operation consuming between forty and forty-five minutes. Following the operation the patient's condition was good. About 11 45 p. m. his pulse suddenly became very weak, his respiration slow and shallow, and he died. The plaintiff's only expert witness did not testify that the patient's death was caused by the negligence of the defendants. He did testify that if a drunken person is operated on that certain bad results may follow, that a general anesthetic given to a drunken person will sometimes throw him into delirium tremens, that a drunken person will require more anesthetic than a sober person, and that there is great danger of heart failure and pneumonia. The undisputed evidence, the court said, showed that the patient did not develop pneumonia, that it did not take more than the usual amount of anesthetic to produce insensibility, that the patient did not vomit as a result of the anesthetic, that the patient's blood pressure was normal, that he did not develop delirium tremens, and that he did not have heart failure either while the operation was being performed or after the operation within the period which the expert witnesses stated it could have occurred as a result of the intoxication. The preponderance of evidence established the fact that the patient's death was the result of a blood clot getting into the blood stream and finding its way to the heart. Eight expert witnesses testified that the patient's death was not due to the fact that he was operated on while intoxicated; none testified that intoxication had anything to do with his death. A physician is not a warrantor of cures nor does the rule of *res ipsa loquitur* apply in a malpractice case. The fact that the operation was not successful does not establish the fact that the physicians were negligent and that such negligence was the proximate cause of the death. Even if there were

evidence that the patient's intoxication was a proximate cause of his death, the evidence also shows, with at least equal clarity, that an embolism may have been the sole proximate cause of the death. The jury will not be permitted to guess which of two causes may have caused the death, verdicts must be based on something more than speculation, conjecture or inference.

The plaintiff contended that it was the duty of the defendants to secure her permission before operating on her husband. While it is true, said the court, that a physician must secure the consent of the parent to operate on a minor, a wife is not the guardian of her husband and her consent is not necessary before a physician is authorized to perform an operation on him.

Concluding that there was no medical expert testimony to establish the fact that the patient's death was proximately caused by the negligence or want of proper care and skill on the part of the defendants, the judgment of the trial court for the defendants was affirmed.—*Barker v Heaney (Texas)*, 82 S W (2d) 417

Malpractice When Arbitration Agreement Does Not Deprive Court of Jurisdiction.—The Ross Loos Medical Group entered into an agreement with the Los Angeles Police Relief Association, whereby the medical group became obligated to furnish certain medical and allied services to subscribers or members of the relief association, and their families. The wife of a member of the relief association alleged malpractice in treatment given her by a physician attached to the medical group, and she and her husband sued the group. The defendant medical group alleged that the cause of action was subject to compulsory arbitration under the terms of the agreement, which provided, in part, that—

Complaints made by either or any of the parties interested shall be forthwith investigated by the Committee of the Relief Association and of the Medical Group. In the event the explanation offered is not satisfactory a board of arbitration shall be selected. Such Board shall meet in arbitration without unnecessary delay and their decision shall be final.

In the judgment of the district court of appeal, second district, division 2, California, the arbitration provisions of the agreement do not apply to personal damage claims by individuals but only to methods and conditions of contact between the contracting parties and their individual members. The arbitration provisions contemplate only an inquiry into a grievance that has been first submitted to a joint committee for explanation, and malpractice is more than a grievance answerable by an explanation. The arbitration agreement did not deprive the trial court of jurisdiction.—*Spanach v Superior Court of Los Angeles County (Calif)*, 43 P (2d) 339

Current Medical Literature

AMERICAN

The Association Library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Protein Stabilization in Eclampsia—Harden and his associates studied the changes in the maternal constitution incident to so-called physiologic gestation, the clinical features of preeclampsia and eclampsia (with reference to the clinical use of an alcoholic extract of liver) and the application of protein stabilization as a measure of study of preeclampsia and eclampsia. The results of their study indicate that the most profound clinical alterations demonstrable in preeclampsia and eclampsia are in the field of protein metabolism that this has a direct application in the final outcome is more than probable. Any plan of prevention and treatment must take into consideration such measures as will tend to maintain the protein of the mother within the limits of normal pregnancy.

Treatment of Dysmenorrhea by Presacral Sympathectomy—Keene states that presacral sympathectomy for dysmenorrhea is limited in its usefulness to young women, and hence its value must be judged not only in terms of relieving pain but also by its effects on menstruation and pregnancy. The operation severs the chief sympathetic nerve supply to the bladder and rectum as well as the uterus and a satisfactory result must include unimpaired function of these organs. His experience, and that of others reported, justify the belief that presacral sympathectomy has a place in the treatment of properly selected cases of functional dysmenorrhea, but its adoption is warranted only when less radical measures have failed. In organic dysmenorrhea, presacral sympathectomy may be used with advantage to supplement operations on the pelvic organs. Ordinarily the operation is not difficult, but conditions may be encountered rendering its performance tedious and hazardous. The operation relieves pain in the majority of cases and does not interfere with menstruation, spontaneous parturition or motor control of the bladder and rectum.

End Results of Labor in Primiparas—Aldridge and Watson observed that the incidence of birth injuries to mothers and babies, and of postpartum complications, was in direct proportion to the incidence of prolonged labor abnormal pelves

faulty presentation and large babies, which resulted in the application of increased pressure to the maternal soft parts and to the fetus during labor and delivery. Elective low forceps after perineal incision can justly be regarded as a prophylactic procedure in patients who would deliver spontaneously if allowed to do so. Perineal incision, when used in conjunction with any type of vaginal operative delivery, consistently reduced the incidence of birth injuries and postpartum complications. Prophylactic methods of delivery should be used by men trained both in obstetrics and in gynecology in hospitals properly equipped to give obstetric care. All women should have the protection of delivery in hospitals under supervision of men trained in gynecology and obstetrics.

Ovary-Stimulating Factors and Antihormones—Fluhmann conducted experiments to study the occurrence of "anti-hormones" in the blood of experimental animals injected daily for a long period of time with gonadotropic extracts. The injection into rats of a preparation of human pituitary gland for ninety or 119 days resulted in the production of substances capable of inhibiting the action of gonadotropic extracts prepared from both human hypophyses and from blood of pregnant women. A species specificity was demonstrable, however, as it proved ineffective with sheep pituitary extracts. The administration to rabbits of a human pregnancy blood gonadotropic extract for seventy-four days resulted in the production of substances capable of inhibiting similar extracts, but it was ineffective against either human or sheep pituitary gland preparations. Antihormones in the blood of women during the first ten days of the puerperium could not be demonstrated.

Basophilic Aggregation Test in Lead Poisoning—McCord and his co-workers assert that in the 1934-1935 epidemic of lead poisoning in the automobile industry 6,900 basophilic aggregation examinations of the blood were made. In addition, during this period 1,100 tests were made in other industries. This number includes approximately 500 control examinations made on workers who were not exposed to lead. Positive basophilic aggregation tests have served as an index for lead absorption prior to the appearance of clinical manifestations of lead poisoning. This test has proved to be of value in

the diagnosis of early cases of lead poisoning. The procedure is suited to application by any physician or laboratory carrying out any blood examinations. The basic principle in the basophilic aggregation test is the enumeration of red blood cells containing basophilic substance, in contrast to the customary procedure of qualitative or quantitative examination for stipple or polychromatophilic cells. The native state of basophilic material in unaltered red blood cells is not known, but in the process of laking and staining red cells this substance may be artificially aggregated into readily visible masses. In normal human adults, these aggregates rarely exceed 1 per cent of the total number of erythrocytes, but in persons exposed to lead the percentages ordinarily lie above this normal maximum, when considerable lead is being absorbed or when clinical lead poisoning is imminent. Finding more than from 1 to 15 per cent and especially more than 2 per cent in persons exposed to lead at once suggests lead absorption and the possibility of approaching lead poisoning, or the actuality of early lead poisoning. In chronic lead poisoning this test usually is not, but may be, positive. As lead poisoning progresses to extended chronicity, the reliability of the procedure diminishes. The test has been utilized in industries using lead to determine the number of exposed workers absorbing lead, as some proof of existing lead hazards, as a guide for the transfer of workers absorbing lead to lead-free departments, as a measure of the efficacy of preventive devices and practices and as a means for the detection of malingers. There are varied types of diseases leading to positive basophilic aggregation tests, but in groups of workers in lead industries, presumably normal except for the possible effects of lead exposures, the positive basophilic aggregation test stands in some relation to lead absorption and its subsequent action.

Bacillus Welchii in Tuberculous Cavities.—Farago obtained positive cultures of *Bacillus Welchii* from 100 per cent of tuberculous cavities bacteriologically studied within a few hours of death. Other species of pathogenic and nonpathogenic anaerobes were isolated in a smaller percentage of cases. Of the *Bacillus Welchii* strains cultivated from cavities, 42 per cent proved to be pathogenic. Sputum from tuberculous patients also gave positive results in 10 per cent of the cases. The author believes that the isolation of *Bacillus Welchii* from a definite though small percentage of sputum from tuberculous cavities lends support to the view that their presence in the cavities at necropsy is not due to dissemination of the organisms after death. While there can be little doubt that conditions suitable for the growth of anaerobic organisms exist in these cavities, the path of invasion by anaerobic bacilli is problematic. Spirochetes have been found in bronchiectatic cavities, but these organisms are present in the pharynx, whereas Branham and Levinthal failed to discover any anaerobic bacilli in the mouth, nose or pharynx. The question of whether these organisms exert any harmful effect on the host is difficult to answer. The fact that in a certain number of cavity cases there was evidence of the formation of antibodies against the hemotoxin and the toxin of *Bacillus Welchii* would suggest that the products of the organism are absorbed from the cavity, but whether in sufficient amount to affect the health of the patient or to retard the process of healing it is impossible for the author to say at present.

Artificial Pneumothorax in Treatment of Lobar Pneumonia.—Burbank and Rothstein treated twenty cases of lobar pneumonia by artificial pneumothorax, with a resulting mortality of 10 per cent. Of their cases, at the onset of treatment, nine had consolidation of the left lower lobe, four of the right lower lobe, two of the right lower and middle lobes, two of the entire right lung and one each of the right upper lobe, of the right middle and upper lobes, and of both lobes of the left lung. With reference to age, the principal factor to be considered is the function of the lungs, as affected by the presence of emphysema and chronic bronchitis. These pulmonary conditions increase with increasing age. The authors have arbitrarily set 60 years as the upper limit, paying less attention to the chronological age than to the presence of diminished breath sounds, fixed barrel chest, numerous rhonchi and a past history of dyspnea on slight exertion. No patients should be treated unless acutely ill, otherwise the percentage of recoveries will be increased falsely. Patients who are febrile past the sixth day are not suitable for treatment while pneumothorax is still in the experimental phase, as many such patients in whom no complications exist will recover. Patients presenting small effusions probably do not offer any contraindications, but until the percentage of empyemas with pneumothorax treatment is established it would be wise not to treat them by this method. None of the authors' patients experienced any immediate pain, shock or discomfort. Relief of pain was permanent, usually after 500 cc. Relief after the first treatment occurred in ten cases, after the second treatment in six more, and four had no pain at any time. There were no immediate complications. Of the twenty patients, two developed empyema. Both were operated on (rib resection and open thoracotomy) and are gradually recovering. Both cases were due to *Streptococcus haemolyticus*. Absorption takes from two to three weeks. Delirium developed in five cases, in three it required restraint. Delirium tremens developed in one case of chronic alcoholism. This patient died. Three patients developed contralateral lobar pneumonia, one of these died. The beneficial effects of pneumothorax are apparently related only to the relief of pleural irritation. There is practically no collapse as seen on the roentgenogram of the involved lobe and no noticeable effect on toxicity, nor is it reasonable to assume a diminution of blood or lymph drainage from the involved areas. The rationale of the therapeutic effect appears to the authors to be as follows. Respiration becomes free, painless and of increased depth. This lessens the exertions of the patient, the cyanosis and anoxemia, and the chance of contralateral diminished aeration with atelectasis and secondary pneumonic involvement. Relief from pain allows the patient to rest comfortably. Sleep is made possible without the use of opiates. Coughing is made almost painless. Productive coughing ensures proper drainage from the diseased area. None of the patients developed abdominal distention. A large part in the development of this troublesome symptom may be played by diaphragmatic pleurisy. Roentgen studies showed air between the lung and the diaphragm in almost all cases and

the relief thus afforded at this point is, the authors feel, directly connected with the absence of distention

Immunologic Applications of Placental Extracts — McKhann and his associates review studies to determine the practicability of immunologic application of placental extracts, particularly in the prevention and modification of measles, and report investigations which indicate that the immune bodies of placental extracts may be effective following oral administration. Tests have been made largely by determination of immunity to scarlet fever as measured by the Dick test. Twenty-two children with positive tests have been rendered Dick negative by oral administration of extract in cold water on an empty stomach. The duration of the negative stage has been variable but has been prolonged to as much as eighteen days if iced alkaline carbonated water is used as the vehicle. The reversal of the Dick test could not be obtained with any regularity in adults. Oral administration of the extract has not been accompanied by reactions.

Fever Therapy in Gonorrheal Arthritis and Chorea — Schnabel and Fetter induced fever by circulating humidified hot air in the Kettering hypertherm in treating nine acute and nine chronic cases of gonorrheal arthritis and twelve cases of Sydenham's chorea. Of the nine patients with acute gonorrheal arthritis, six were cured, two were markedly improved and one was moderately improved. Of the nine with chronic gonorrheal arthritis, five were cured, three markedly improved and one moderately improved. Nine patients with chorea were cured and two were markedly improved. One died as a result of a disturbance of his heat regulating mechanism. No patient having either of these diseases failed to respond favorably to this form of treatment. It is believed that fever therapy offers the best chance of cure for both gonorrheal arthritis and chorea.

Fatal Diabetic Coma with Acute Renal Failure — Holmes presents five cases of fatal diabetic coma, all with blood nonprotein nitrogen retention of more than 100 mg per hundred cubic centimeters, observed in the past five years. All cases fell properly in the class of diabetic acidosis as judged by the usual clinical and laboratory criteria: excessive hyperglycemia, reduction of the alkali reserve of the plasma, glycosuria and ketonuria. The principal features of the cases were the failure of the acidosis, as exemplified by the plasma carbon dioxide combining power, to clear in response to insulin therapy, and the development of evidence of renal insufficiency. All patients seemed to respond favorably to treatment at first and all revived for a brief period a few hours after treatment was begun, only to lapse back into a fatal stupor and finally die in apparent uremia. Oliguria was noted in all cases and anuria, for from six to twenty-two hours, in four individuals. Casts and red and white blood cells were present in the urine of all patients. Albuminuria, although slight at first, increased as the coma progressed. The nonprotein nitrogen of the blood, while not markedly elevated early, gradually mounted in each case until before death it exceeded 100 mg per hundred cubic centimeters, in one case it exceeded 300 mg per hundred cubic centimeters on the eighth day. Edema was noted in three instances toward the end, and convulsions (hypoglycemia not present) developed in one patient. While moderate amounts of acetone were present in the urine in all cases, diacetic acid was absent in one and present only in small amounts in the urine of the other four. The increase in the blood nonprotein nitrogen is probably not entirely an index of failure of kidney function, since concentration of the chemical constituents including urea is brought about by dehydration always present in severe diabetic coma. However, in the series, the grade of nitrogen retention was much greater than that reported as a result of dehydration, and the retention occurred late after the anhydremia had apparently been overcome by the administration of large amounts of fluids. The presence of oliguria, anuria, albumin, casts and red blood cells in the urine, edema, and in one patient convulsions, can leave little doubt that the severe azotemia in these cases was due to direct retention as a result of acute functional renal failure. Several factors have been suggested as being concerned in the development of this type of renal failure: shock, dehydration disturbance of the plasma electrolytes increased destruction of endogenous protein, insulin and pathologic change in the kidney. Most of these factors are probably interrelated.

Ménère's Syndrome and Endolymph Decompression with Improvement—Parkinson reports a case of so-called Ménère's syndrome and suggests the descriptive term recurrent aural crisis. Endolymph decompression, as described by Portmann, was performed on the involved side. The effect was promptly and favorably to modify the course of symptoms sufficient to rehabilitate the patient. Continued deterioration in auditory and vestibular function indicates that the disease process has not been terminated in spite of symptomatic relief. The relation of endolymph decompression to the symptomatic course of this disease may be significant in studies aimed at etiology and pathology. It seems consistent with Furstenburg's work on salt retention. It suggests that the endolymph is concerned in the pathology and in the production of the characteristic attacks.

Corneal Ulcers Due to Common Allergen.—Parlato presents a case of corneal ulcers, the cause of which was traced to a hypersensitivity to orris root. Specific treatments were given, and for the past two years there has been no recurrence.

of the ulcers. The accompanying disease of the lids and the rest of the conjunctiva have disappeared. Evidence is submitted to show that ethylmorphine hydrochloride is contraindicated in the palliative treatment of corneal ulcers. An allergic study of other cases of corneal ulcers will elicit the basic etiologic factors and thus increase the percentage of successful treatments. The timely recognition of hypersensitivity in many cases of chronic conjunctivitis in which the condition proves refractory to the usual forms of treatment may help to prevent the formation of corneal ulcers and the subsequent impairment of vision.

Changes in Knee Joint in Rheumatoid Arthritis—Parker and Keefer compared the lesions of three cases of rheumatoid arthritis with those of degenerative and infectious arthritis. They obtained necropsies in two of the cases; the process was in a comparatively early stage in one and was far advanced in the other. The early case occurred in a person who died from cinchophen poisoning. They observed that destruction of the articulating cartilage takes place by solution and by dedifferentiation of cartilage into connective tissue once its surface has been covered with connective tissue. It is replaced with cancellous bone by a process of ossification from the periphery. The destruction of cartilage by connective tissue growing into the cartilage from the subchondral spaces is minimal and not a fundamental pathologic process in the disease. It is seen when new bone formation goes on in such areas. From their observations the authors state that the fundamental process in rheumatoid arthritis is an inflammatory process in the periarticular tissues and synovial membrane. The other anatomic changes are secondary to this essential change, that is to say, the destruction of cartilage, the atrophy of bone and new bone formation. A part of the process can be explained on the basis of disuse of a joint together with the loss of cartilage that occurs following the connective tissue overgrowth. Any theory that attempts to explain the pathogenesis of rheumatoid arthritis must take into account the mechanism by which the changes in the periarticular tissues come into being. The lesions in the cartilage, which are so distinctive of degenerative arthritis, are quite different from those resulting from destruction of the cartilage by overgrowth of connective tissue. The theory that degenerative and rheumatoid arthritis result from the same underlying factors is untenable.

Diffuse Cortical Contusion of Occipital Lobe—Courville bases his discussion of diffuse cortical contusions of the occipital lobe, which are relatively uncommon, on eight cases in which necropsies were performed. With the exception of those due to depressed fractures, they assume certain characteristics which are of interest in the study of traumatic intracranial lesions. Diffuse contusion of the occipital lobe, characterized by a diffuse reddish coloration and softening of the affected cortex without gross morphologic disorganization results from two types of mechanical disturbance. The lesion may be primary and acute, resulting from forcing of the occipital cortex against the falx or tentorium when the head in motion strikes some relatively immovable object. The force of the blow is expended on the sides or top of the head. Although in the primary type the contusion of the brain is usually found on the same side as that of the injury to the scalp, it occurs on the opposite side of the occipital lobe and is therefore a contrecoup. The secondary type is the result of local pressure by an expanding lesion, such as edema or subdural or intracerebral hemorrhage. In this type there is no necessary relationship between the side of the original injury and that of the contusion. In any case the lesion

is essentially a diffuse hemorrhagic softening of the cortex resulting from a rupture of small cortical veins incident to the sudden reversal of current in these vessels in the primary type, or to persistent and increasing obstruction by continued pressure in the secondary type. Microscopically, the cortical and subcortical tissues are found to be infiltrated with blood. The softening and disintegrating tissues are ultimately filled with compound granular corpuscles. The appearance of the ultimate lesion is unknown, since no example has as yet been studied.

Paget's Disease (Osteitis Deformans)—Moehlig and Murphy observed that in twelve cases of Paget's disease five gave a family history of diabetes mellitus. In two cases more than one member of the family had diabetes, and in one of these both parents died of diabetes and a brother, still living, is so afflicted. It was noted that a sister in this family had had a parathyroidectomy for generalized osteoporosis. There was at least one member in each of the families of the twelve patients who was 70 inches (178 cm) or more in height. There were five different patients in whose families the weight of one or more members exceeded 200 pounds (91 Kg). Two of the subjects with Paget's disease had leiomyomas. The authors suggest that the function of the pituitary gland is involved primarily in the production of the disease process and that the function of the parathyroid is involved secondarily. From a practical therapeutic standpoint the first consideration would be one of constitutional prophylaxis, that is, a eugenic one in that the tall, obese individuals, especially those with a familial diabetic history, should not intermarry. In view of the fact that there is a familial diabetic history and the patients have a low

carbohydrate tolerance, victims of Paget's disease should be treated as diabetic, with weighed diet and insulin

Parathyroids and Sex Hormones in Tetany.—The sex glands have a pronounced effect on the neuromuscular excitability in human parathyroid tetany. McCullagh and Kearns did not find variations in amounts of sex hormones in the body to be correlated with alterations in the levels of serum calcium and phosphorus, and it appears probable that they affect neuromuscular excitability through a separate mechanism. The application of radiation therapy to the ovaries is suggested as a possible means of controlling some of the aggravating factors in tetany in selected cases.

Mental Retardation.—Gordon and Kuskin studied 666 mentally retarded children, of whom 266 showed signs of endocrine disorder. Mental retardation occurred with the greatest frequency in association with (in the order named) childhood myxedema, hypothyroidism, pituitary obesity (adiposogenital dystrophy and thyropituitary type), anterior pituitary deficiency of growth and goiter. Mentally retarded infants with endocrine conditions were found to cut teeth, walk and talk at a later date than mentally normal infants in the same endocrine groups. Practically all children with childhood myxedema in this series were mentally retarded and showed delay in all developmental fields. There was found a greater tendency for mental retardation associated with childhood myxedema and hypothyroidism to appear in the first two years of life. Mental retardation in association with pituitary disturbances appeared to a greater extent after the second year of life. A concomitant appearance of mental retardation and endocrine dyscrasia was found to the greatest extent in childhood myxedema, to a lesser degree in hypothyroidism and to the least extent in pituitary conditions. It appeared that mental retardation occurs more frequently after an acute illness in association with pituitary disturbance and hypothyroidism than with childhood myxedema. A history of trauma is present only in the pituitary group and in not a single instance in the thyroid class in this series. Congenital syphilis played an insignificant part in the production of endocrine disorder (5.5 per cent). The incidence of congenital syphilis was only 8 per cent in the nonendocrine group of mental retardation. Every child with mental retardation should be studied from a comprehensive endocrine point of view.

Organotherapy in Mental Retardation.—Gordon and his associates treated 155 mentally retarded children who showed endocrine dyscrasia and 162 children showing nonendocrine mental retardation. The treatment consisted of organotherapy (desiccated thyroid and pituitary gland), remedial measures of associated disabilities such as chronic diseases, proper diet, educational measures and improvement of social conditions. Diet, improvement in social conditions and elimination of physical disabilities had no effect on the mental status in any child. The change in mentality was due then to the action of organotherapy or of the educational measures. The part played by the latter is great, but, since practically all children of school age, especially those in the lower intelligence quotient classes, had the benefit of an educational program it must be concluded that any beneficial results are to be attributed to the effects of glandular preparations. A tendency to continued improvement was observed in 45 per cent of the endocrine group and in 1.2 per cent of the nonendocrine group. Fair or temporary results were obtained in 34 per cent of the endocrine and in 34.6 per cent of the nonendocrine group. A tendency to continued improvement following the administration of desiccated thyroid and pituitary glands was observed only in cases of mental retardation associated with endocrine disorder. The highest incidence was noted in anterior pituitary deficiency, childhood myxedema, hypothyroidism and pituitary obesity, in the order named. Better results (58 per cent) were obtained in thyroid disturbances than in the hypopituitary group (30 per cent).

Tubercle Bacilli on Lips of Patients.—Gulbrandsen and Keller show that viable tubercle bacilli reside on the lips of patients with open pulmonary tuberculosis. Tubercle bacilli exposed on the surface of the body in this way have abundant opportunity to be transferred from the lips to the hands and fingers, or from the lips to whatever utensil or article comes into contact with them. As a result, persons working or living in an environment of tuberculosis have as much possibility of becoming infected with the tubercle bacillus through actual contact as one would of becoming infected with other types of bacteria from typhoid or diphtheria carriers. Opie and McPherson found that when roentgen examinations were used for the recognition of pulmonary lesions, husbands and wives in marital contact with tuberculosis under varying conditions were infected from five to nine times as often as persons with no known contact with the disease. Evarts, Potter and Dunn followed the children of 136 families into adult life. At least one parent in each family was known to have had tuberculosis. Among 554 children of these families, the tuberculosis mortality in offspring between the ages of 15 and 39 years was two and three times as high as among the general population of the same class of people. Meyers, Diehl and Lees pointed out that 39 per cent of nurses in training, in a tuberculosis service of thirty beds, presented positive reactions on entrance, whereas three years later on graduation, 100 per cent had positive tuberculin reactions. Apparently tubercle bacilli are being disseminated along avenues that are not encompassed by present methods of tuberculosis control, that is, prevention of droplet infection. As more is understood in regard to this disease, these measures must be supplemented by closer attention to existing sources of infection. The patient with tubercle bacilli in his sputum must be looked on as a "carrier" of tubercle bacilli with the same public health status as a carrier of typhoid or diphtheria. Consequently, if measures are to be taken to prevent dissemination of tubercle bacilli exposed on a body surface in this way, these measures must be concentrated on the patient. The authors' recommendations consist of instructing the patient with regard to personal hygiene. Along with the proper disposal of sputum he should be taught that tubercle bacilli reside constantly on his lips, and therefore any object that comes in contact with these structures such as fingers, hands, tableware of any type and towels, have an opportunity of becoming contaminated with tubercle bacilli. Adequate facilities should be provided for washing the hands and lips at frequent intervals, in order to maintain the self-disinfecting power of the skin at its highest activity at all times. All the principles of medical asepsis as practiced in regard to other infectious and communicable diseases should be instituted in the care of tuberculous patients. Tubercle bacilli found on the lips of patients having open pulmonary tuberculosis can survive for periods of one hour and forty minutes and still be viable.

Use of Prostheses over Unightly Eyes—In a case in which enucleation was considered, Schneider recommended the wearing of a very thin contact glasslike prosthesis over the injured eye. The patient has been wearing the thin prosthesis continuously and with perfect comfort and satisfaction. This experience leads the author to believe that (1) enucleation for an unsightly but comfortable eye may not be indicated, (2) an artificial eye can be made thin enough to be worn successfully over an unshrunk globe, (3) a patient can soon wear such a prosthesis with comfort, and (4) the mobility of the prosthesis, when riding over a natural globe with normal musculature, is certain to be much better than when the prosthesis is resting on any sort of stump.

Scarlet Fever Toxin—Dick and Boor show the advantages of a purified and concentrated toxin for skin test and immunologic purposes and for a study of the chemical and physical properties of this substance. They have prepared a purified and concentrated scarlatinal toxin containing 20,000,000 or more skin test doses per gram and of low nitrogen content by a combination of fractional precipitation with ammonium sulfate, treatment with an aluminum hydroxide preparation, dialysis and evaporation.

Variation in Corynebacterium Diphtheriae—Hobby studied the morphologic and colonial variation in Corynebacterium diphtheriae and observed the relation of bacteriophage to this variation. Working with a particular strain, which has been designated RB-2T, variation in both liquid and solid mediums has been investigated. A spontaneous variation leading to a change from the rod to the coccoid form, and the reverse, has been observed. Mucoid, smooth, rough and minute colonies of the rod form of this strain and mucoid and smooth colonies of the coccoid form have been isolated. A rough type, consisting of filamentous, branching rods, has been derived from the smooth phase of the coccoid form. A transformation from the smooth phase of the coccoid form to the smooth phase of the rod form may occur through the intermediate stage of the rough phase derived from the coccoid form. Single cell cultures of the coccoid form in the mucoid and smooth phases have been shown to be completely susceptible to the action of races of bacteriophage isolated (1) from the intestinal contents of typical cases of diphtheria, (2) from the intestinal contents and peritoneal washings of guinea-pigs infected with diphtheria bacilli and (3) from broth cultures that have stood at room temperature for from four to six weeks. Single cell cultures of the rod form in the mucoid smooth and rough phases are completely resistant to the bacteriophage. Eight races of bacteriophage,

isolated under anaerobic conditions from lysogenic variants of the smooth type of the rod form, are active against the coccoid form in the mucoid and smooth phases but not against any other forms of this strain. No correlation between virulence and toxigenicity has been observed. Results show that the virulence of the rod form is increased by the presence of bacteriophage, which is active in vitro only against the coccoid form. The ability of the coccoid form to produce toxin has been shown for the first time, thus indicating a fundamental relation between this form and the characteristic rod form.

Primary Sarcoma Associated with Primary Carcinoma.—Curphey discusses a case of two malignant tumors occurring simultaneously in the same breast, which he considers belong in the group of separate primary malignant growths, principally because of the existing anatomic arrangement. In the light of Russell's experimental work it is possible that the carcinoma might have had sarcoma propagating properties similar to mouse tumor 100. This is unlikely in the present instance because the metastatic carcinoma in the liver had no associated sarcomatous growth, there was no tendency for the sarcoma to overgrow the carcinoma, a phenomena that occurred almost invariably in Russell's mouse tumor. That the carcinoma might have been secondary to the sarcoma is also plausible according to the observations of Nicholson. In other words, either of the two tumors might have stimulated the growth of the other or both might be entirely independent and caused by the same ultimate factor that is responsible for all malignant growth.

Symptoms of Cholelithiasis—Zollinger and Young distended the gallbladder or common duct in six patients. Under a short gas oxygen anesthesia or local infiltration of procaine hydrochloride the stones were removed from the gallbladder or common duct, and a sterile balloon was inserted which could be distended and the pressure recorded. When the patient had recovered sufficiently from the anesthesia to answer all questions intelligently, the gallbladder or common duct was distended. Distention of the gallbladder produced a feeling of indigestion or deep epigastric discomfort without the usual pain referred to the back or discomfort in the right hypochondrium. Nausea and vomiting did not occur, regardless of the degree of distention. Distention of the common duct produced a more severe epigastric distress, but again pain was not referred to the back. Inspiratory distress was characteristic of distention of either viscus. The chief difference between distention of the gallbladder and of the common duct was the occurrence of nausea and vomiting with the latter. The significance of these observations was then determined from a study of the clinical histories of 100 cases of cholelithiasis and chronic cholecystitis with a negative history for jaundice, 100 cases of acute cholecystitis and 100 cases of proved stone of the common duct. The authors' observations, which showed that vomiting followed distention of the common duct were in accord clinically in that distention of the biliary ducts, as by a calculus, produced a high percentage of involuntary vomiting as compared with calculi within the gallbladder. They believe that a calculus in the cystic or common duct in patients having pronounced involuntary vomiting should be considered in the group of indications for exploration of the common duct.

Coronary Disease in Youth—White states that the male sex is overwhelmingly the victim of coronary disease in early life. The young patients of his series all used considerable tobacco. The question of ancestral longevity and inheritance is undoubtedly important. His data give some support to the widely held notion that it is of fundamental importance to inherit long lived ancestors. Two points of some interest concerning the young patients with coronary disease are that they live city lives and have not exercised consistently. Infections do not seem to play much of a part in the production of serious coronary disease nor does diet, although further study may show that, as in diabetes, it is the combination of faulty metabolism with faulty diet that is important. The author has collected the data in cases of coronary thrombosis and of uncomplicated angina pectoris occurring in patients less than

40 years of age, examined in the last fifteen years, for comparison with his total series of cases of coronary thrombosis and of angina pectoris at all ages. He compares certain features about these cases and others in children less than 5 years of age with similar features concerning a group of very old persons, ranging in age from 80 to 105 years and for the most part in good health. In the latter he found that he could use the data that Pearl has been collecting somewhat in the same way concerning nonagenarians and centenarians.

Functional Puberty Bleeding and Its Treatment by Endocrine Therapy—When no pathologic condition of the pelvis, as elicited by bimanual examination, could account for bleeding in young girls, Witherspoon and Collins instituted endocrine therapy before any curettage was performed. The technic of the treatment consisted in the daily administration to the bleeding patient of 1 cc of a preparation of the anterior pituitary-like gonadotropic principle from the urine of pregnant women, alone or in combination with 2 cc. of a commercial preparation containing the anterior pituitary growth factor. These injections are given intramuscularly and are continued until the bleeding stops. Assuming this cessation of flow to be the end of a menstrual period, no further therapy is given until the onset of the next period. With the onset of flow, daily injections are again given until the flow of the second period ceases. In like manner treatment is carried through a third period. After treatment for three months, no treatment is administered during the fourth period, in the hope that the menstrual rhythm has reestablished itself. If such is not the case, treatment should be carried on a while longer. In the authors' experience three periods of treatment were usually sufficient to reestablish the normal menstrual rhythm. About equal results were obtained whether the gonadotropic principle was used alone or in combination with the growth principle. The only untoward symptoms noted were an occasional local reaction at the site of the injections. This could be somewhat alleviated by decreasing the dosage given, starting with smaller doses or by diluting the amount of the injection with an equal volume of physiologic solution of sodium chloride or a 0.5 per cent solution of procaine hydrochloride. That actual conversion of the hyperplastic endometrium over into the secretory, premenstrual phase did not always occur is readily attested in several cases by the rapid cessation of flow, within from twelve to twenty-four hours, after the injections. The most likely explanation would seem to be that the effect is exerted on some unknown bleeding factor, which possibly is similar in nature and function to the principle that controls the cessation of the normal menstrual flow.

Agranulocytosis Following Quinine Administration.—Vitug and his associates point out that some patients who take quinine often complain of marked body weakness, besides the usual auditory disturbance. It is probable that the granulocytic mechanism of such patients is adversely affected by the

drug Their patient received no drug other than quinine bisulfate While the patient was taking the drug her temperature (which had been normal) rose suddenly on the fifth day and remained at 40 C (104 F) for several days Following the mere suspension of quinine, the fever dropped to 37.8 C (100 F) The authors are inclined to interpret this fact as evidence that the drug acted as a bone marrow depressant, with special stress on the myelocytic center Discontinuance of the drug allowed granulopoiesis to proceed normally and thus contributed to the lowering of the temperature The prompt increase of the granular leukocytes following a blood transfusion coinciding with a further drop of the temperature to the normal level seems to substantiate the hypothesis of Roberts and Kracke that one of the functions of the granulocytes may be to aid in heat control The slight but progressive fall in the total leukocyte and polymorphonuclear counts noted on the readministration of quinine to the patient at a reduced dosage after she had recovered from her leukopenic crisis is to the authors positive proof that they are dealing with a quinine-induced agranulocytosis

Age Incidence of Causes of Illness—Collins presents the results of periodic canvasses of 8758 white families living in 130 localities in eighteen states and including 39,185 individuals Each family was visited at intervals of from two to four months for a period long enough to obtain a sickness record for one year On the first call a record was made of the number of members of the household, together with data about sex, age, marital status and communicable disease history of each person On succeeding visits the canvasser recorded all illness that had occurred since the preceding call, with such pertinent facts about each case as the date of onset, the duration of disability and of confinement to bed, the nature of such medical service as was obtained, and the termination of the illness The surveyed families include representation from nearly all geographic sections, from rural, urban and metropolitan areas and from all income classes, and consist of both native born and foreign born persons The proportions of these various elements included are not identical with those in the population of the United States, but the variations are not generally large In other respects also the surveyed group is not dissimilar to families in the general white population of the United States The age incidence of all the specific diseases that were reported in sufficient numbers to approximate a reasonably accurate age curve are depicted in graphs and tables While there are irregular chance variations in many of the curves, they serve to indicate the general picture of the age incidence of even the less frequent diagnoses

*Ketogenic Diet in Persistent Pyuria Pearl Summerfeldt, Marion M. Johnston and Mildred J Kaake.—p 389

Urinary Disorders in Neonatal Period—Craig describes the abnormal microscopic and bacteriologic observations in the urine of sixty-one new-born children with urinary disorders and gives details of the clinical signs and symptoms The urinary observations are compared with those in a series of healthy new-born children The abnormalities present in the urine were varied Organisms were present in every case and pus was present in large amount in fifty-three cases excessive deposits of uric acid and urates were noted in twenty cases, in five of which there was no pyuria A characteristic clinical picture is found in association with urinary conditions in the new-born Onset of the illness is usually indefinite prolonged anuria, especially when accompanied by fever or occasional vomiting is suggestive of a commencing urinary condition and justifies immediate diuretic treatment Later, restlessness, thirst and sweating develop and color changes are characteristic of the illness at its height Collapse occasionally occurs and high fever is common, but in a few cases the course is afebrile. Convulsions are of grave significance. Symptoms are closely related to the excretory activity of the kidneys, and treatment should be directed toward the promotion and maintenance of adequate diuresis This is best attained by the giving of fluids at frequent intervals and the administration of alkalis and weak tea A follow up of children after their discharge from the hospital showed that recovery is complete, remissions rarely occur and the subsequent general health of the children is not impaired. Urinary infection in the neonatal period occasionally occurs either as a complication of intracranial birth injury or in association with severe alimentary disturbance. In fatal cases pathologic changes are slight they are most often found in the substance of the kidney and rarely involve the pelvis of the organ

Recurrent Swelling of Parotid Glands—Pearson cites eleven cases of recurrent swelling of the parotid gland characterized by the absence of infection and by the frequent history of allergy In three cases, allergic manifestations frequently coincided with the development of the swellings In one of these the passage of plugs containing large numbers of eosinophils from the parotid duct is described It is suggested that these swellings may be allergic in nature The possible mechanism of the swellings is discussed and obstruction of the ducts is thought to play a prominent part Infection may in some cases be superimposed on an allergic basis

Ketogenic Diet in Persistent Pyuria—Summerfeldt and her associates state that to compare the ketogenic diet with the surgical treatment of persistent pyuria is difficult, as the principle of surgical treatment is to relieve the obstruction to allow free drainage and to reduce the pressure atrophy on the kidney, aiming at some restoration of kidney tissue if no further obstruction occurs With this treatment these children usually do well, but in seven cases in which cultures of the urine were taken for from eight months to four years after the relief of the obstruction, micro-organisms were still found to be present. With the ketogenic diet and the production of sterile urine it can well be argued that kidney infection is eliminated, but just how rapidly or to what extent the hydronephrosis will progress is not known. This will have to be controlled with further intravenous pyelography and cystoscopic examinations That this form of treatment is not always effective is shown by the fact that 21 per cent did not become bacteria free, though one case was not under observation long enough for a fair trial.

In 14 per cent there was a recurrence of the pyuria in six months and eight months and in the remaining 65 per cent of cases the results are good. Surgical treatment of chronic pyelitis serves merely to relieve the anatomic irregularity with the idea that the establishment of adequate drainage will remove the focus of infection. No bactericidal principle is provided to hasten the return of proper healthy function. The ketogenic diet does not correct anatomic anomalies but does provide the bactericidal agent. From a study of the two types of treatment it would appear that a combination is to be recommended to obtain the best results.

***Plasmodium Knowlesi* in Treatment of Dementia Paralytica**—In order to overcome certain difficulties associated with the induction of benign tertian malaria for the treatment of dementia paralytica, van Rooyen and Pile employed the naturally occurring ape malaria parasite *Plasmodium Knowlesi*, which they have successfully transmitted to twelve human subjects. They investigated the practical applicability of substituting this type of parasite for *Plasmodium vivax* in the treatment of dementia paralytica and present two cases that illustrate the application of this form of infection in the treatment of the disease. Clinical notes concerning the course of ape malaria occurring in man, the action of certain antimalarial remedies on this type of infection and various experimental data are also discussed. The work has been carried out with a strain of parasite originally obtained from the Malaria Survey of India, supplied by Rickard Christophers of London.

Scabies in a Mental Hospital—Kingston discusses and stresses the inadequacy of sulfur ointment in the treatment of scabies. In view of the dogmatic optimism to be found in textbooks of dermatology with regard to the treatment of scabies by sulfur ointment he emphasizes the following of the recorded observations. Of ten certain cases of scabies in mental patients, not one was cured by two courses of sulfur ointment treatment. A total of thirty three courses of treatment resulted in five cures and five failures. At room temperature an adult female sarcoptes will survive complete embedding in sulfur ointment for twenty-four hours. At room temperature the eggs will survive and continue to develop for four days in sulfur ointment and it does not prevent the larvae

from hatching out. On the other hand, sulfur ointment is more lethal for the sarcoptes than petrolatum, killing the parasite in half the time. A 2 per cent solution of sulfated potash in water is markedly toxic for the parasite but loses its potency if allowed to become neutralized by the carbon dioxide of the atmosphere. This fact prevented any satisfactory experiment with the reagent at the strength of the sulfated potash bath as usually prescribed (i.e., about 1:1,500). The author experimented with sulfur, turpentine and paraffin and found it to be disappointing clinically. Apparently potent when applied directly to the parasite at a concentration that caused little or no irritation to the skin it frequently failed to cure the patient even when given as rather liberal applications on three successive days. On the other hand for a certain type of patient it is undoubtedly superior to sulfur ointment. The treatment may be repeated the following week without ill effect, and this course is probably advisable in any well established case. The preparation is simple and cheap, and the opening up of burrows, although doubtless of benefit, is not an essential factor in the treatment.

Some Notes and Comments on Surgical Records of the Brisbane Hospital During Last Quarter of Century E S Meyers—p 405
Convergence Accommodation and Pupil Contraction G Phillips—p 412

Basal Metabolic Rates Obtained by Gasometric Analysis and Formulas—Frank made a comparison of basal metabolic rates by indirect calorimetry (Douglas bag and Haldane gas analysis), and by Read's, modified Read's and Gales' formulas in 250 patients. There is a large margin of inaccuracy in the determinations by the formulas. In only approximately one fifth of the cases was there an error of less than 5 per cent, while in more than 30 per cent of the cases there was an error of more than 20 per cent. Frequently when low basal metabolic rates were obtained by gas analysis the formula gave higher readings. The reverse occurred in hyperthyroidism, and here lower readings were observed frequently. The formula might find some practical value as a method in difficulties if its limitations are recognized. Possibly it might be used to follow up patients with hyperthyroidism who are under treatment provided the initial value of the gasometric result is known. Even here its results are not conclusively diagnostic. The percentage and margin of error by the formulas are too great and incalculable. It does not allow a sufficiently certain estimation, especially in important and difficult cases. Therefore the author feels justified in issuing a warning against making a final diagnosis from the use of formulas alone. Deviations of gasometric basal metabolism from the normal alone are insufficient proof of an endocrine upset and are not to be used diagnostically except in association with the total clinical picture. The gasometric analysis for determination of the basal metabolic rate cannot be supplemented or replaced by formulas.

*Laryngeal Crises and Certain Vasomotor Crises of Head J A Chavany and S Daum—p 1505

Vasomotor Crises in Tabes—Chavany and Daum describe three cases of laryngeal crisis occurring in tabes dorsalis. They say that the light form is a simple spasm without dyspnea, properly speaking, but with immediate congestion of the face. The lesser form involves true dyspnea with a suffocating spasm. The dominating element is the contracture of the constrictors of the larynx. The vasomotor signs appear secondary to the asphyxial state. In the severe form there is sudden congestion of the face followed by pallor, usually with loss of consciousness, convulsions and sometimes sudden death. The mechanism of these attacks is poorly understood. The abruptness of onset suggests a reflex mechanism, but the excitant is unknown. The neurovegetative explanation accords with some of the clinical phenomena. Thus it accounts for the disproportion between excitant and intensity and severity of the responses encountered. The condition occurs frequently in tabes, and it is known that neurovegetative disturbances are common in this disease. The evidence, therefore, though not conclusive is highly suggestive.

Cavitation Form of Bronchiectasis—Bezançon and his co-workers describe three personally observed cases and one case reported elsewhere of large solitary bronchiectatic cavities surrounded by normal lung tissue. The actual existence of the cavity and its bronchiectatic nature were verified in one case by necropsy. In another case, stereoscopic roentgenograms showed the connection of the cavity with the bronchus and the existence of associated ampullary dilatations. In the other two, intrabronchial iodized poppy-seed oil confirmed the diagnosis. Clinically the condition shares the general symptomatology of bronchiectasis. In no instance was there any previous pulmonary or bronchial history before the sudden onset of serious hemoptysis accompanied by abundant expectoration. The microscopic appearances of these cavities are similar to those found in general bronchial dilatations.

Emesis in Infants Due to Air Swallowing—Lereboullet and his associates studied the vomitings that occur in infants from swallowing air. Roentgenologic examination has allowed several obscure points to be elucidated. The physiologic action of the pharynx in allowing much more air to be swallowed with liquids than with solids or semisolids is the principal factor. The mode in which air acts is apparently by creating the intragastric pressure necessary to provoke gastric contraction. The rapidity of the distention plays an important part in producing this condition, which is thus shown to be physiologic rather than pathologic. Three measures of treatment are given. The process may be avoided by direct introduction, by means of a tube, of the liquid food into the stomach, thus avoiding the function of the pharynx. Increase in the consistency of the food does much to decrease the amount of air swallowed. Finally, taking the left lateral decubitus position immediately after eating favors the pyloric evacuation of the intragastric air and decreases the gastric distention.

Treatment of Pulmonary Abscess—Simon and Magrou report four cases of nonpurulent pulmonary abscesses treated by means of intravenous injections of alcohol by the Landau method. This consisted in the daily injection of 10 cc. of a 20 per cent solution of alcohol intravenously. The amount and percentage strength of the solution were sometimes increased later. Serial roentgenograms were made. In two of the patients one could speak of recovery, in the other two marked improvement resulted. The mechanism of action is still uncertain,

but they conclude that this method of treatment may be attempted with a high degree of success, without serious complications, and may be continued without fear when improvement has begun to be noticed.

Blood Transfusions in Chronic Skin Disorders.—Kuske describes the history of a patient with a generalized arsenamine exanthem in whom, after all other methods of treatment had failed, a blood transfusion was tried. The first transfusion of 350 cc of blood resulted in a considerable improvement of the general condition. A second transfusion resulted in further betterment, so that the local treatment of the skin could be discontinued. Blood transfusions proved effective in three other cases of arsenamine dermatitis. The author cites a case of generalized seborrheal eczema in which the usual therapeutic armamentarium had been exhausted. A single transfusion of 200 cc. of citrated blood was soon followed by a great improvement. The author employs the following technic of transfusion. He withdraws from 200 to 300 cc. of blood from the donor, mixes it in a ratio of 10:1 with a 3.5 per cent solution of sodium citrate, adds to this approximately 100 cc. of physiologic solution of sodium chloride, and then transfuses it slowly.

*Diagnostic Importance of Dry Preparations of Organic Fluids. P De Gara—p 1393

Diagnostic Use of Dry Preparations of Organic Fluids.—De Gara examined eighty specimens, both normal and pathologic, of cerebrospinal fluid, of gastric juice and of pleural and ascitic exudates by the test reported by Henning and co-laborators (*Klin Wchenschr* 13: 251 [Feb 17] 1934, abstr *THE JOURNAL*, April 28, 1934, p 1445). The test consists in the microscopic examination of the dried drop of the organic fluid for certain observations made in the original technic. The author states that the test can be used advantageously for detection of albumin, which, when present, becomes manifest in the marginal ring zone, the extension of which is proportional to the content of albumin in the fluid. The drop on the slide, treated by Milton's test in these cases, gives positive results. The technic of Henning's test is simpler than that of other tests for detection of albumin, while the results of the former agree with those of the latter. As the dry preparations are hygroscopic, they can be kept indefinitely in closed containers with calcium chloride.

*Treatment of Burns by Vitamins and Camphor in Oil C O Franzetti—p 998

Treatment of Burns by Vitamins and Camphor in Oil—In treating severe and infected burns, Franzetti reports satisfactory results from a combined internal and local treatment that consists in the administration of daily doses of from 20 to 30 drops of a solution of vitamins A and D, prepared at a concentration of 12,000 vitamin units each per cubic centimeter of the solvent, and the application of camphor in oil (at a 7 per cent concentration) dressings over the entire burned area. The local infection, general intoxication, edemas, vomiting, fever, tachycardia and albuminuria that complicate large, deep seated and infected burns rapidly diminished until complete disappearance. The renal functions rapidly become normal and the local results, especially those related to the formation of scars, are gratifying. The author has treated several cases with success.

Hydrosalpinx After Sterilization.—Koller describes the histories of three women in whom hydrosalpinx developed after a sterilizing intervention. In the first case one tube was treated according to Madlener's method, while the other tube was closed by double crushing and ligation. In the second case the tubes were crushed and ligated at three points. The third case was that of a woman in whom in the course of an operation for extra-uterine pregnancy the other tube was closed by a simple ligature. The author considers the closure of the tubes by an infection or the artificial closure by a ligature the chief cause of the later development of hydrosalpinx. He is unable to say to what extent postoperative circulatory disturbances increase the transudation but points out that the most severe sacosalpinx developed in the tube on which Madlener's operation was done, a method in which crushing and ligation of a larger portion of the tubes will always lead to changes in the circulation. The author also cites a number of animal experiments. On the basis of the observations described here and of a great number of sterilizations, he reaches the conclusion that a sterilizing intervention should be preceded by a control of the temperature, of the number of leukocytes and of the sedimentation speed of the erythrocytes, and that it should not be done unless these tests indicate normal values. Sterilization should not be done until at least eight weeks has passed after a confinement, an abortion or a general disorder. In case of thrombotic disturbances or of genital inflammations, the waiting period should be still longer. Careful peritonization of the region of the wound is necessary. Ligated portions of tissue and those the nutrition of which is impaired should if possible be secured by retroperitoneal burying (prevention of ileus). The sterilization methods should employ as simple a method as possible. The author says that his clinic has used within the last year subperitoneal resection without ligation of the tubes and with subsequent peritoneal suture. He advises that all surgical sterilizations be made at the isthmus portion of the tubes near their connection with the uterus. He thinks that in this manner it will be possible to prevent the formation of a hydrosalpinx or of a later, ascending pyosalpinx. If the operation reveals inflammatory changes of the tubes or if there is a possibility of closure in the ampullar portion and at the abdominal ostium, the total resection of the tubes, eventually with wedge excision from the uterine fundus, is advisable. It is hoped that this will prevent the formation of a hydrosalpinx or of a flare-up of latent infections.

Plural Births.—Steiner says that until a decade ago it was generally assumed that uniovular twins are always covered by one chorion and that twins who have two chorions are always binovular. In recent years, investigations have disclosed that the results of the examination of the placenta do not always tally with the similarity diagnosis. To determine whether discrepancies exist between similarity diagnoses and postpartum observations, the author's institute has collected twin placentas since 1928. The number of chorions and amnions was determined by macroscopic and microscopic studies, and in some cases the placental circulations were examined by means of contrast injections and stereoröntgenoscopies. The twins were subjected to similarity diagnoses between the sixth and twelfth months and again during later years. The similarity examinations in 100 twins of the same sex and with dichorionic placentas disclosed that twenty-four were uniovular and that seventy-five were binovular. Studies on twenty-nine monochorionic-diamniotic and on three monochorionic-monoamniotic twins

disclosed that they were all uniovular. One hundred and thirty-six sets of twins of different sexes had dichorionic placentas. The author observed no monochorionic placentas in twins of different sexes. Double placentas were found in dichorionic uniovular twins just as frequently as in binovular twins and in twins of different sexes. He points out that so far the research on twins has disclosed nothing that would justify a departure from the opinion that monochorionic-diamniotic twins are always uniovular and thus biotypical. The presence of a monochorionic-diamniotic placenta proves that the twins in question are uniovular. Monochorionic-monoamniotic twins are most likely uniovular. In order to make the diagnosis "monochorionic-diamniotic placenta" it is necessary, in addition to the macroscopic determination of a simple placenta and of a septum that consists of two membranes, to discover anastomoses between the two placental circulations. A microscopic examination of the septum should be made, because it is the only means of deciding the diagnosis if vascular anastomoses cannot be found. The same rules apply to the examination of the placentas of triplets or of other plural births. Among seven sets of triplets, the author discovered two trichorionic binovular sets. The examined individuals of plural births who had a common chorion were without exception uniovular. The similarity between dichorionic uniovular twins is the same as in case of monochorionic uniovular twins. Dichorionic uniovular twins are true uniovular twins.

Increase in Blood Pressure an Indication of Incretory Disturbances in Myoma.—To clarify the problem of whether the development of myoma is connected with circulatory disturbances that are not the result of loss of blood, Strassmann and Philipp determined the blood pressure values of 500 patients with myoma and compared them with the blood pressure values of 500 patients of the same age groups who had different disorders. They found that low values (under 120 mm of mercury) were present in 15.4 per cent of the patients with myoma and in 28.6 per cent of the other patients. High blood pressure values (over 140 mm of mercury) were found in 43.6 per cent of the myoma patients and in 33 per cent of the other patients. These figures are the more noteworthy since they include also the myoma patients in whom severe hemorrhages had depressed the blood pressure values. Of the myoma patients who had a regular menstrual cycle (460 women), 42.16 per cent had values over 140 mm of mercury whereas in the regularly menstruating women with the other disorders (387) this percentage was 25. Since the menopause and the menopausal increase in blood pressure appear later in myoma patients than in other women, the comparison of those in both groups, who menstruate regularly, reveals the blood pressure increasing factor of the myoma disorder more clearly than the comparison of corresponding age groups. The authors emphasize that the increase in the blood pressure in the myoma patients is not a direct result of the tumor but that both are coordinate symptoms of a superordinated incretory disturbance, which may be considered a dysfunction of the ovary, the thyroid and the adrenals. This is indicated also by the increased basal metabolic rate, the electrocardiographic aspects and the outcome of Kauffmann's diuresis test in patients with myoma. The authors point out that, although for the gynecologist the local aspects of the uterus are the most important in case of myoma, it should not be overlooked that this is a general disorder the circulatory and incretory disturbances of which deserve attention. On the other hand, the internist should not fail to search for a myoma in the corresponding disorders of other organs.

*Fertility Vitamin E and Its Therapeutic Significance for Gynecology. E. Gierhake—p 1674

Rare Gynecologic Disorders in Children.—Clauberg says that leukorrhea is the chief disorder for which the gynecologist is consulted in the treatment of children and young girls. The

first thing to be done in these cases is the bacteriologic examination in order to determine whether the vulvovaginitis is of gonorrheal origin. If this is not the case, two factors must be considered which are nearly always responsible for leukorrhea in children and young girls, namely, irritation by foreign bodies and malignant tumors. The author reports the case of a girl, aged 4, in whom a peculiar vaginal tumor existed. Radium proved to be ineffective in the treatment of the highly malignant tumor, and the child died. On the basis of the histologic examination, the tumor must be regarded as an angioendothelioma. The author says that such tumors are much less frequent than irritation by a foreign body and asserts that onanistic practices are more common in small girls than is ordinarily believed. He describes the case of a girl, aged 6, in whom manipulations with a slate pencil were found to be the cause of the leukorrhea, and in a girl aged 8, small stones and two safety pins were extracted from the vagina. He cites the case of a girl who fell astride an iron bar, on which she tried to balance herself. There was hemorrhage from the vulva but no severe external injury. When the bleeding continued an intervention became necessary, in the course of which it was found that the vagina had been completely torn off. In the last part of his report the author describes the injuries sustained by a child, aged 2 years and 3 months, who was raped.

Vitamin E—Gierhake reports his own studies on the so-called fertility vitamin. He made tests on rats and chickens and found that the lack of vitamin E in the diet is followed by sterility by changes in the instinctive behavior of the animals and by changes in the hairs and feathers, respectively, that is, there is evidence of an excretory disturbance, particularly of the anterior lobe of the hypophysis. Histologic studies on the hypophysis of the animals receiving a diet in which vitamin E was lacking revealed changes similar to those that develop following castration. There are indications that the lack of vitamin E results primarily in an impairment of the gonads, which in turn produces the changes in the hypophysis. Following the method suggested by Evans and Burr, the author succeeded in preparing from the oil of wheat germ a concentrated extract of vitamin E a few drops of which reestablished fertility in female rats made sterile by a diet lacking in vitamin E. After mentioning the physical and chemical properties of this extract, he discusses its therapeutic application, pointing out that in several countries preparations of vitamin E have been used with good results in human and veterinary medicine. He thinks that treatment with vitamin E is indicated in habitual abortion, in cases in which there is a tendency to premature births, and in all cases of female sterility in which a dietetic insufficiency seems to play a part.

Therapy of Essential Thrombopenia—Schiff describes the history of a boy, aged 9, who presented the typical symptoms of essential thrombopenia. The child was given a diet consisting of fresh fruits, vegetables, liver and five egg yolks and 0.15 Gm of cevitic acid daily. After a few days of this treatment there was considerable improvement in the bleeding tendency. The bleeding time likewise improved rapidly, although the number of platelets was still comparatively small. Moreover, after about twelve days the capillary resistance had improved considerably and the thrombocytes increased constantly, so that after one month they numbered 200,000 and at the end of four months 413,000. The author raises the question as to what caused this thrombocytosis, the cevitic acid or the fat-soluble vitamins and provitamins contained in the egg yolks. In order to gain some insight into this problem, he employed a somewhat different treatment in another child with essential thrombopenia, a girl aged 7. The child was treated in the same manner as the boy, except that she received

no egg yolks and liver. It is noteworthy that in this child there was a considerable decrease in the number of thrombocytes during the first eight days of treatment. However, in spite of the small number of thrombocytes, the bleeding tendency and the bleeding time improved. After the cevitic acid was administered intravenously, the number of thrombocytes increased rapidly, but beginning with the twenty second day of treatment the child received the cevitic acid only orally. In comparing the two cases, the author points out that in the first child, who received the cevitic acid only by mouth and, in addition, was given egg yolks, the increase in thrombocytes was more rapid than in the second child, in whom the cevitic acid was administered by mouth as well as intravenously. The author is as yet unable to decide whether the more rapid increase in the thrombocytes of the first child was the result of the egg yolks or whether individual differences in the two patients are responsible for the different results. These two cases indicate also that there is no parallelism between the bleeding time and the number of thrombocytes.

Experiments on Percutaneous Insulin Action.—Hermann and Kassowitz demonstrate in experiments on animals that insulin in the form of a suitable ointment is not only absorbed by the skin but can be applied in measurable doses so as to produce repeatedly the same effects. They determined that the skin absorbs insulin in two ways, which, for the sake of clearness, are designated as "vertical" and "horizontal." In reality the percutaneous insulin action consists of two components, the one designated as the "vertical" produces a reduction in the blood sugar as in case of subcutaneous injection, whereas the "horizontal" results in a slower but also a more protracted insulin action. The authors observed that, to realize the full insulin action it is necessary to remove the fat and cholesterol from the skin and to alkalinize or at least neutralize, the skin, because the free organic acids that exist in the skin or in the sweat of omnivorous animals prevent the percutaneous insulin action. Theoretical reasoning seems to justify the hypothesis that a part of the percutaneously applied insulin is absorbed by the lymph, whereas the other part goes by the shortest route to the musculature.

Percutaneous Action of Insulin in Diabetic Patients.—Pribram points out that the experiments of Hermann and Kassowitz demonstrated that an insulin ointment applied under the proper conditions to the skin of rabbits and dogs is capable of reducing the blood sugar. This induced him to make experiments on healthy persons and on diabetic patients. Tests on healthy persons revealed that insulin rubbed into the skin is absorbed and produces a reduction of the blood sugar. He tried the percutaneous insulin administration on more than twenty patients with diabetes mellitus. The observations made in these patients are summarized as follows: 1 Insulin applied to the skin reduces the blood sugar content. 2 The quantity of insulin required for percutaneous administration is much greater than that required for subcutaneous administration (five times as much). 3 The amount of insulin required generally varies between 50 and 300 units. 4 The skin should be cleansed and the ointment applied according to the method of Hermann and Kassowitz. The sites of application are alternately the regions of the biceps and of the anterior portions of the thighs. 5 The immediate effect of the percutaneously administered insulin is small, and short tests generally prove ineffective, however, if the injection is done with persistence, favorable results can be obtained in many cases. The author concedes that percutaneous insulin treatment is unsuited for severe cases of diabetes mellitus.

Although the large insulin doses make the injection method rather expensive, the method has the advantage that it effects a more protracted action, and, since sudden and severe reductions in the blood sugar do not have to be feared with this method of application, it would seem advisable for diabetic patients who have circulatory disturbances. The author describes several cases in which he employed the treatment. The first case demonstrates that if the same dose is adhered to the efficacy of the insulin injection increases gradually.

Hemostatic Action of Pectins—Sick describes his experiences with a solution of apple pectin. He administers this solution either by injection in the form of a sterile 15 per cent solution or by mouth in the form of a 5 per cent solution. Depending on the severity of the hemorrhage, he administers from 20 to 80 cc, partly by subcutaneous injection and partly by intragluteal injection, the latter being the most effective. As soon as the coagulation time had been reduced, the patient was given four times daily 10 cc of the pectin solution by mouth. The author employed the pectin treatment in thirty-two cases: ten gastric hemorrhages, seven pulmonary hemorrhages, three renal and vesical hemorrhages, two intestinal hemorrhages, six other cases (nasal and dental hemorrhages and so on), one patient with icterus and three patients with hemophilia. All these cases, some of which were rather severe, responded promptly to the treatment. The author describes some of the histories, particularly those of the hemophilic patients. It was always possible to reduce the abnormally high coagulation time to normal values. The pectin solution proved its hemostatic value also when locally applied, and its administration never produced undesirable effects.

*Treatment of Epidemic Parotitis K Oxenius—p 1714

*Treatment of Hemorrhoids T Sutter—p 1715

Röntgen Irradiation of Tonsils H Loebell—p 1715

Serodiagnosis of Scarlet Fever—The serodiagnosis of scarlet fever suggested by Weichherz employs substrates (antigen and antibodies, respectively) from the blood of scarlet fever patients. He prepared one from the blood serum of a patient who had had scarlet fever for four days, the other from the blood serum of a scarlet fever convalescent. He used the globulin fraction as antibody substrate and the albumin fraction as antigen substrate. The serums to be tested were incubated with these two substrates and then treated further according to the method used by Fuchs in the diagnosis of cancer. The author employed this test in seventy cases of scarlet fever and obtained correct results in sixty-eight. The reaction was always negative in measles, varicella and medicinal exanthems. These promising results induced the author to make this brief preliminary report, which is to be followed later by a more detailed one.

Treatment of Epidemic Parotitis—Oxenius considers prolonged rest in bed (two weeks) unnecessary in the treatment of epidemic parotitis but he admits that several days rest in bed might be advisable for the prevention of complications. In reviewing the measures that most therapeutic textbooks recommend for the treatment of parotitis he expresses the opinion that oral irrigations with hydrogen peroxide are inadvisable. Instead he advises particularly for children gargling and oral irrigations with a mild tea of peppermint sage or camomile, pointing out that these teas are much more pleasant in that they do not produce the deadened feeling in the oral mucous membrane that is produced by hydrogen peroxide. Moreover he suggests that the sucking of medicated tablets is likewise helpful. In view of the favorable result obtained with antiphlogistic cataplasms in the treatment of inflammations of the lymph nodes the author decided to use these cataplasms in the case of epidemic parotitis and obtained good results. These cataplasms require only one change in twenty-four hours and were well liked by the patients.

Treatment of Hemorrhoids—Sutter shows that the withdrawal of the blood from the nodules and their surroundings is highly important in the treatment of hemorrhoids. In order

to effect this, two factors are important: (1) emptying of the veins by muscular activity of the legs and (2) the diversion of the blood into other parts of the body. The author shows that both of these factors are accomplished by swimming, but that mere bathing is ineffective. He describes three cases in which swimming proved helpful in the treatment of hemorrhoids.

Point of Attack of Thyroxine B von Issekutz—p 1325

Present Opinions on Etiology of Essential Hypertension E Kylin—p 1330

Bendien's Reaction for Diagnosis of Cancer—Hogenauer and Grobl review the technic of Bendien's test and the results obtained by other investigators. Then they describe their own experiences with the test on 116 cancer patients and 143 control cases. They obtained positive results in 103 of the cancer patients. However they also obtained positive results in sixty-nine of the control cases. They conclude from this that the positive outcome of Bendien's test does not justify the diagnosis of cancer. The negative outcome of the test, together with other factors that militate against cancer, however, may eventually corroborate the absence of cancer. Bendien's reaction is of but slight value for the clinical diagnosis of cancer.

*Treatment of Retarded Births R Berg—p 2483

*Two New Methods of Ventrosuspension by Cutting of Round Ligaments R Milner—p 2484

Treatment of Retarded Births—Berg says that the same reasoning which led to the administration of belladonna during the period of dilatation induced him to try methyloctenylamine, a spasmolytic preparation. He found that the injection of 1 cc of this preparation was highly effective in overcoming the rigidity of the uterine os. During the period of expulsion he obtained favorable results with the combined subcutaneous injection of 1 cc of the same preparation and with from 15 to 3 Voegtlin units of posterior pituitary. He found that this combination had a better effect than posterior pituitary alone. He gained the impression that spasmolytic preparation has the effect of an activator. He maintains that with this treatment the period of expulsion is shortened without detrimental effects.

Ventrosuspension by Cutting of Round Ligaments—Milner says that in case of prolapse of the vagina and the uterus the methods employed hitherto for ventrifixation did not obviate the danger of ileus. He achieves mobile anterior fixation of the uterus by cutting the round ligaments. For cases in which the round ligaments are so short that they cannot be pulled through the anterior abdominal wall or for those in which attachment to the anterior fascia (the posterior one being usually too weak) was made impossible by this shortness, the author devised what he considers a new way of ventrosuspension. He cuts the round ligaments as far laterally from the uterus as possible, separates them from the broad ligaments, sutures the slits into the broad ligaments, covers the round ligaments with peritoneum and then pulls them through the anterior abdominal wall according to Gilliam's method. The author employed this method also in a case in which the round ligaments were not too short but too thin. He says that whether the fascia of the abdominal wall is divided in the longitudinal or the transverse direction depends on the individual case. It is important that the round ligaments are not crushed with a clamp in that portion with which they are to be attached. The pulling through of the simple round ligament instead of a loop has the advantage that the opening may be smaller. This smallness is of importance for the prevention of hernias and of prolapse of the omentum. If his technic is used suturing of the lateral portion of the round ligament is unnecessary. The use of the cut ligaments gives greater freedom as far as tightness and height of the attachment are concerned, especially in the rather frequent cases in which

chiefly the uterus is prolapsed. This method permits also a restriction of the operations that constrict the vagina. The intervention is possible in two ways: transperitoneal or subperitoneal. In the latter case there is no danger of ileus, whereas in the former it exists only as far as the lateral clefts between anterior abdominal wall and round ligaments are concerned. The other threat of ileus in transperitoneal attachment can readily be prevented by peritoneal sutures.

Buffer Capacity of Morphologic Elements of the Blood B. M. Chuistov — p 1364

Pernicious Anemia—Sherman studied seventy-six cases of pernicious anemia. He concludes that the most characteristic features of the blood picture in the acute stage of the disease is the presence of megalocytes and a pronounced polysegmentation of the neutrophils. Other characteristics, such as acute anemia with a high color index, leukopenia, neutropenia, lymphocytosis, monopenia, aneosinophilia, eosinopenia and thrombopenia, are seen as well in hyperchromic anemias of types other than the Biermer-Erlach type. Patients with pernicious anemia show pronounced alterations in the functions of the small and large intestines, manifested as a rule by the presence of a fermenting, putrid colitis (92 per cent). Of these, 84 per cent had an enterocolitis. Study of feces on Schmidt's diet demonstrated lack of utilization of fats in 92 per cent and lack of digestion of muscle fibers in 70 per cent. The ferment function of the pancreas was decreased in half of the studied cases. In the majority of the cases faulty carbohydrate metabolism was present. This was manifested by a low blood sugar on fasting, a high glycemic coefficient on administration of sugar, and failure to return to normal figures two hours after the beginning of the sugar tolerance test. The author emphasizes the diagnostic importance of glossitis as an early symptom. This was present in 90 per cent of the cases. Subjective neurologic and vascular symptoms play an important part in the clinical picture of pernicious anemia.

*Genesis of Oval Erythrocytes H. Scharf Hansen — p 348
*Observations on Insulin-Epinephrine Treatment by Clausen Method T. T. Andersen — p 361

Sarcoid of Boeck—Salvesen emphasizes that the sarcoid of Boeck is of interest to the internist because it is not merely a skin disease but, like Hodgkin's disease, may involve the entire organism. It is a systemic disease with especial preference for the lymphatic system. The author describes the histories of four patients: one man and three women ranging in age from 38 to 56 years. Two of the patients presented symptoms that had not been described in Boeck's sarcoid. One of the women suffered from a contracted kidney with peculiar clinical aspects. Besides skin sarcoids and pulmonary lesions of the usual type, she had low blood pressure and neuritis of the optic nerves. Another woman, aged 38, had a heart lesion with right bundle branch block of an unstable type, partly dependent on the heart rate. The author reproduces a number of electrocardiograms. One of them taken under the influence of amyl nitrite, shows transition from normal conduction to block and from block to normal again. The man had glandular tumors, iridocyclitis, enlarged spleen and extensive pulmonary infiltration for three years before the skin sarcoid appeared. In the three

patients examined for it there was a considerable increase in the serum protein, owing to a greater amount of globulin.

Latent Edema in Tonsillar Angina—Kristenson is convinced that infections involve always a toxic impairment of the body tissues. One of the most frequent functional disorders resulting from the toxic action of infections is a cardiovascular disturbance. The cardiac action and the peripheral circulation are impaired. Manifestations of the latter disturbance are changes in the fluid exchange between the blood and tissues. The volume of the involved portion of the body enlarges to the extent to which the disturbance in the fluid exchange between blood and tissues increases the fluid content of the tissues. This increase in volume can be measured by different methods. The author describes the method that he employed first on normal persons, then on patients with mild infections and finally on patients with tonsillar angina. In healthy persons fifteen minutes of standing increased the volume of the leg by from 0.6 to 2.5 per cent. This increase disappeared within thirty minutes after the horizontal position had been assumed. In persons with infections of the upper air passages, particularly in those with tonsillar angina, the course of the test was different, either the increase in volume was greater than in normal persons or it did not disappear with the normal rapidity when the horizontal position was assumed. The author concludes from this that the existing infection produces a tissue impairment with functional disturbance of the fluid exchange between the blood and the tissues.

Genesis of Oval Erythrocytes—After remarks about the occurrence of oval erythrocytes in various species of animals, Scharf Hansen points out that in human subjects they appear during pernicious anemia in the form of macro-ovalocytes and usually disappear after successful liver therapy. However, the literature also reports cases of healthy persons in whom comparatively high percentages of oval erythrocytes were observed. Recently the author observed a woman, aged 50, who was hospitalized on account of chronic rheumatism. Examination of the blood revealed 67 per cent hemoglobin and 402 million erythrocytes. Closer inspection of the erythrocytes after staining with May-Grünwald-Giemsa demonstrated that the majority of the erythrocytes were oval, some of them of small elliptic shape. Repeated examinations of the blood always revealed the same oval erythrocytes amounting to approximately 90 per cent of the total number. In order to determine during what stage of the erythropoiesis the oval form developed, a sternal puncture was made which disclosed entirely normal conditions, that is, the erythroblasts and erythrocytes were all round. This indicates that the oval form does not develop until after karyorrhexis has taken place. Studies on the reticulocytes revealed that the transformation into ovalocytes takes place during or immediately after the reticular stage of the erythrocytes. In order to determine whether ovalocytosis is hereditary the blood of three of the seven children of the woman was examined. Two girls had only round erythrocytes, whereas a boy, aged 14, had some oval erythrocytes. To be sure, in him the ovalocytosis was not as pronounced as in his mother. Nevertheless, his case indicates that ovalocytosis may be hereditary. Studies of the form of erythrocytes of normal and anemic persons disclosed that ovalocytes (disregarding megalocytes) occur regularly and amount to from 1 to 20 per thousand of the erythrocytes. The number of the ovalocytes seems to increase slightly with age and with the degree of anemia. The author assumes that the ovalocytes might represent the final stage, "the stage of destruction" of all erythrocytes and that the cause of ovalocytosis may be an endocrine factor.

Observations on Insulin-Epinephrine Treatment—The favorable results obtained by Clausen with the combined administration of insulin and epinephrine induced Andersen to try this method. The amount of epinephrine added was 0.1 mg to 5 cc. of insulin. This addition of epinephrine caused no local reactions. Andersen employed this treatment in seventeen cases. None of these patients showed detrimental effects. Those in whom the insulin treatment alone had produced hypoglycemic symptoms were entirely free from them after the epinephrine had been added. The author considers this form of treatment especially useful in diabetic patients with a tendency to hypoglycemic reactions.

INTERMITTENT PRESSURE AND SUCTION

IN THE TREATMENT OF CHRONIC OCCLUSIVE
ARTERIAL DISEASE

EDGAR V ALLEN, M D
AND
GEORGE E. BROWN, M D
ROCHESTER, MINN

The historical background for the use of alternate suction and pressure in the treatment of vascular disease has been reviewed by Herrmann and Reid¹. In spite of the fact that such treatment is a century and a quarter old, a great deal of credit is due to Landis and Gibbon² and to Reid and Herrmann³ for reviving it, for perfecting the mechanism by which it is applied, and for testing the value of the treatment both physiologically and clinically. Herrmann and Reid⁴ have proposed the name "pavaex" for this treatment, the term signifying passive vascular exercise, and the changes in pressure being gradual. Landis⁵ has retained the denotation "alternate pressure and suction," the changes in pressure being sudden. At the clinic, we have used the unit devised by Herrmann and Reid since February 1934. In the present paper we attempt to evaluate this therapeutic procedure from a review of cases in the literature in which it was used and from a survey of our own experiences with it. Unfortunately, there have appeared from nonmedical sources extremely enthusiastic reports. These have made imperative a sound survey based on actual clinical trial.

REVIEW OF LITERATURE

Physiologic Studies of Normal Subjects and Studies on a Circulation Schema—Alternate suction and pressure in the treatment of occlusive vascular disease has a physiologic basis. Landis and Gibbon have shown that it increases the flow of water through a circulation schema. The results seem to be based on Pousselles' law that the amount of fluid flowing through a rigid tube depends on the fall of pressure along that tube. Landis and Gibbon further demonstrated that the rate at which the extremities of normal subjects cooled when such subjects were placed in a cool environment

was slowed by the changing environmental pressure. They found, likewise, that the warmth of cool extremities of normal subjects was increased by alternating suction and pressure.

Studies on Patients with Occlusive Arterial Disease, Surface Temperature—Landis and Gibbon studied five patients with occlusive arterial disease. The average rise in the temperature of the digits exposed to suction and pressure was 71 degrees C, whereas the temperature of the opposite extremity increased on an average of 19 degrees C. Subsequently, Landis reported observations of sixteen patients with occlusive arterial disease. The digits of feet exposed to alternate pressure and suction became warmer by an average of 76 degrees C, whereas the rise in temperature of opposite extremities averaged 18 degrees C. In several publications Herrmann and Reid also reported an increase in the temperature of the skin of subjects with occlusive arterial disease although definite figures were not given. Reid⁶ likewise reported an increase in the temperature of the skin. The duration of this increase in temperature of the skin as a result of treatment persists about seventy-two hours according to Herrmann and Reid,⁴ although there is a gradual diminution in the surface temperature after about twelve hours. Landis stated that the hyperemia is maintained for several hours. Evidence that vasodilatation persists permanently after discontinuance of treatment has not been presented, although Landis stated that it usually becomes more and more lasting as treatment continues. Herrmann and Reid reported that they had no information concerning the permanence of the increase in temperature.

Effect on Pain—There are four common types of pain observed in chronic occlusive arterial disease: Intermittent claudication is distress produced by exercise which is relieved by rest. Rest pain is a more or less constant distress occurring independent of exercise. We recognize three main types: (1) that in the region of ulceration or gangrene, (2) that associated with ischemic neuritis, and (3) that following sudden arterial occlusion, which appears to be due to widespread arterial spasm. Unfortunately for attempts at evaluation, references in the literature are all too frequently vague as regards type of pain. Statements made were that the major symptoms were relieved or that the patients were subjectively improved. Such statements confuse the issue and make true evaluation difficult.

Pain of Ulceration or Gangrene—Landis reported that four patients with frank gangrene or large sloughing ulcers received little or only temporary benefit. Amputation was necessary in all four cases. Seven

patients with indolent or slowly enlarging ulcers were entirely or almost entirely relieved of pain. De Takats⁸ reported that all his patients afflicted with rest pain were promptly relieved but that the pain returned when treatment was discontinued. Shipley and Yaeger⁹ reported prompt relief in two cases. Landis and Hitzrot¹⁰ reported total relief of pain in regions of ulceration in five of six cases of diabetes and arteriosclerosis, and improvement in one case. In the same condition, rest pain unassociated with trophic lesions was relieved entirely in four cases and was improved in one case. Of seven cases of thrombo-angitis obliterans, pain associated with ulceration was relieved permanently in three cases and improved in two cases, in the two remaining cases, pain was relieved only during a period of treatment. In an additional case of thrombo-angitis obliterans, rest pain that was not associated with ulceration was relieved. In two of three cases of arteriosclerosis with ulceration, pain was relieved, in one case, relief was experienced only during a treatment.

Pain Associated with Sudden Arterial Occlusion. Herrmann and Reid¹ reported ten such cases, in all of which pain was relieved promptly. De Takats specifically noted relief in one of his cases and stated that all patients with rest pain were relieved during treatment.

Intermittent Claudication. Landis noted lengthening of the walking distance before claudication occurred in five of six cases. In de Takats' series no improvement was noted in cases of thrombo-angitis obliterans, but increased tolerance to distance was noted in four cases of "endarteritis obliterans." Landis and Hitzrot noted improvement in claudication in two of three cases of diabetes and arteriosclerosis and all six cases of thrombo-angitis obliterans. Herrmann and Reid reported complete relief in one case of sudden arterial occlusion.

Inadequately Defined Pain. Shipley and Yaeger reported subjective improvement of three patients. Herrmann and Reid¹ reported complete relief in three of nineteen cases, in eight cases there was improvement, and in eight others improvement was not noted. In all these cases a diagnosis of "predominant involvement of the arterioles of the feet" was made. In forty-six cases a diagnosis of "predominant involvement of the secondary arterial pathways" was made, and in twenty cases it was reported that patients were "completely relieved of all major symptoms." Twenty-two additional patients were "greatly improved" as far as pain was concerned.

Effect on Frank Gangrene.—The affected extremities of all four of Landis's patients required amputation. Herrmann and Reid¹ reported that 16 per cent of sixty-five patients with "predominant involvement of secondary arterial pathways," and "predominant involvement of the arterioles of the feet" due to arteriosclerosis, required amputation of the affected extremities. Gangrene seemed to be definitely limited, and in some instances amputation was possible at a lower level as a result of treatment. All ten patients who had sudden arterial occlusion, some of whom might reasonably be expected to have gangrene later, avoided it as a result of treatment. Three patients

with sudden arterial occlusion observed by de Takats did not show improvement as far as the gangrene was concerned.

Effect on Indolent Ulcers.—De Takats reported the healing of an ulcer in a case of "endarteritis obliterans" and the marked tendency of another ulcer to heal in a case of arteriosclerosis obliterans. Shipley and Yaeger reported the healing of ulcers in a case of thrombo-angitis obliterans and in another case of thrombo-arteriosclerosis obliterans. Landis noted no improvement in the appearance of gangrenous sloughs in two cases of thrombo-angitis obliterans and only temporary improvement in one case of thrombo-arteriosclerosis obliterans. In four cases of thrombo-angitis obliterans and in three cases of thrombo-arteriosclerosis obliterans, indolent ulcers healed. Landis and Hitzrot reported acceleration of or complete healing in eight cases of arteriosclerosis and diabetes, amputation was necessary in one case because of osteomyelitis and in one case because of a persistent slough and necrosis of a toe that occurred six months later. Ulcers healed entirely or markedly in four of six cases of thrombo-angitis obliterans, amputation being necessary in the other two cases, and ulcers healed in two of three cases of arteriosclerosis, amputation being necessary in the third case.

From these reported observations, one can draw the conclusions that the surface temperature of the treated extremity usually increases significantly during a treatment and that the duration of this increase has not been definitely determined. As yet no definite evidence has been presented that permanent vasodilatation has been induced by repeated treatment. Indolent ulcers may heal as a result of treatment. Rest pain is usually relieved while the patient is receiving treatment, but it frequently returns, in some cases the pain disappears more or less permanently. Claudication is usually benefited. Gangrene can be avoided in cases of sudden arterial occlusion if the patients are treated soon after occlusion occurs.

EXPERIENCE AT THE MAYO CLINIC

Sixty patients have been treated at the clinic with the passive vascular exercise unit, thirty-two of these over sufficient periods to allow some evaluation of the method. Sixty or eighty millimeters of negative and 20 mm of positive pressure (four cycles to each minute) were used as a routine procedure. All patients were confined to the hospital and only minimal activity was allowed. Those with gangrene or ulceration received anodynes and alcohol, anesthetics and stimulants to epithelial growth were applied locally, as needed, and foot soaks of saturated boric acid were given. Most of the patients took postural exercises and the feet were kept warm in a cradle or cabinet by heat from carbon filament bulbs. Additional treatment given is indicated in the accompanying tables. In these tables and in the discussion that follows, the terms "ischemic neuritis" and "trophic pain" are used to describe conditions as indicated by Goldsmith and Brown.

Ischemic Neuritis.—Seven patients with thrombo-arteriosclerosis obliterans and four with thrombo-angitis obliterans were treated at the clinic (table 1). In all but two cases pain was relieved during a period of treatment. In these two cases, distress was increased by treatment and could not be tolerated. Of the nine other patients who obtained relief during a period of treatment, three were permanently and completely

§ Elsewhere

relieved and four were permanently relieved to a degree of about 50 to 75 per cent. In two cases relief was experienced only during active treatment, but pain returned shortly after the extremity was removed from the glass boot.

Trophic Pain—Six of the twelve patients with thrombo-angitis obliterans experienced permanent relief of pain (table 2). In three cases pain was increased by treatment and in three cases it was unchanged. Trophic pain was present in five of the seven cases of thrombo-arteriosclerosis obliterans, relief was experienced in three and absent in two of these cases (table 3).

Trophic Changes and Gangrene—Of the ten patients with thrombo-angitis obliterans who could tolerate the method, four had very marked improvement of gangrene or ulcers and six had none. Two of the four patients who were markedly benefited received repeated intravenous injections of typhoid vaccine, the one with digital gangrene and ulceration had normal pulsations in the posterior tibial artery. The prognosis in this type of case is almost invariably good. Marked benefit was noted in trophic changes in five of the

Pain Associated with Sudden Arterial Occlusion—Two patients with sudden arterial occlusion were treated on the second and sixth days, respectively, after the onset of the condition. In both cases pain and discoloration of the foot were increased by treatment. One patient who had sudden arterial closure about eight hours before treatment was begun was completely relieved of pain but gangrene occurred.

Skin Temperature—Determinations of the temperature of the skin of thirty-five patients were made before and after sixty-eight treatments. The average temperature before treatment was 29 C (84.2 F) and the average at the end of the sixty-eight treatments was 31 C (87.8 F), a net gain of 2 degrees C. The increase in the temperature of the skin as a result of treatment doubtless would have been larger if temperatures at the beginning of the treatments had been less than 29 C. The significance of these readings of skin temperature is vitiated somewhat by the fact that, while the room temperature varied within normal limits, it was not constant. The duration of the increases in temperature was not definitely determined, but it was less than twenty-four hours, for almost without excep-

‡ Includes routine methods of treatment used at the clinic.

seven cases of thrombo-arteriosclerosis obliterans. The most conspicuous failure was in the last case. In spite of almost ten weeks of treatment, a small superficial ulcer progressed, eventually necessitating amputation. In all the cases in which improvement was noted, the lesions at the beginning were minimal.

Amputation was necessary in all of three cases of sudden arterial occlusion because of gangrene. Two patients were referred to us and passive vascular exercise was begun on the second and sixth days, respectively, after the onset of the condition. Progressive gangrene developed in one case following sudden arterial occlusion, in spite of almost continuous treatment begun only eight hours after the occlusion occurred. Pain was completely relieved.

One patient had frozen his fingers severely while lying intimated in the snow for an unknown period of time in subzero weather. Seventy-five hours of treatment in fifteen days did not in any regard avoid the necessity for amputation of the digits.

Intermittent Claudication—Three patients with thrombo-angitis obliterans were specifically tested for evidence of improvement of claudication. A standard test was used. The patients walked at the rate of 120 steps a minute until they could not continue. They received, respectively, twenty-six, eighteen and forty-three hours of treatment. No benefit was noted.

tion the temperature twenty-four hours after completion of treatment was approximately the same as when treatment was begun. In no instance was there evidence of a permanent increase in the temperature of the skin as a result of repeated treatments.

Comparison of Results of Passive Vascular Exercise with Those of Other Methods—As a preliminary it is well to state that occlusive arterial diseases, especially thrombo-angitis obliterans, are notoriously subject to exacerbations and remissions, to periods of quiescence and activity. Even those most experienced in caring for patients with these diseases may have difficulty in determining what results follow natural changes in the course of the disease and what results are induced by artificial means. Experience with a large number of patients is helpful.

The chief aim of all treatment is preservation of affected limbs. Too frequently overlooked, however, is the fact that in many instances amputation is the happiest solution when it obviates long periods of disability and expensive and frequently unfruitful treatment. Any treatment, to be of great value, must therefore produce reasonably prompt results. The average patient cannot afford the money or the time for daily treatments over a period of months, and he usually prefers having his diseased leg replaced with a wooden one so that he can return promptly to work.

It is well to attempt comparison of results that follow the use of intermittent suction and pressure with those that follow other types of treatment. Increases in surface temperature can be accomplished by the artificial induction of fever, by immersion of the hands in warm water, and by the ingestion of alcohol, theobromine and mechohim. All these methods are simpler than treatment with alternate suction and pressure. One may reason, logically, that unusual benefit will ensue from treatment with alternate suction and pressure only if the increase in circulation is permanent, since similar increases can be induced temporarily by simpler methods.

Permanent relief of rest pain, if effected, is a distinct attribute of the method. Barker, however, reported that as a result of treatment of thrombo-angitis obliterans with typhoid vaccine there was a complete or almost complete relief in 86 per cent of twenty-eight cases in which rest pain was present but in which there were no trophic changes, and in 73 per cent of fifty cases in which rest pain was associated with trophic ulcers. In 65 per cent of forty-six cases of gangrene limited to digits, and in 25 per cent of cases of massive gangrene pain was likewise relieved by typhoid vaccine. Permanent relief of pain by section of peripheral nerves has been reported by Laskey and Silbert.¹¹

The good results reported in sudden arterial occlusion are encouraging, but Denk¹² reported almost equally good results from intravenous injection of a papaverine substitute. In one case observed by Allen and MacLean,¹³ papaverine was injected intravenously with good results. It is well known that about one half of patients with sudden arterial occlusion recover when very simple methods of treatment are used. The report of Herrmann and Reid that all ten patients recovered when the alternate suction and pressure method was used indicates a distinct advance. Two of our three cases cannot be considered fair tests, as occlusion had taken place too long before treatment was begun. The relief of intermittent claudication is also of great interest. Careful investigation of many patients with this symptom has indicated that the patient's statement is commonly unreliable. Accurate tests should be carried out. We determine the distance at which claudication occurs by walking patients at a standard pace of 120 steps each minute. The distance at which claudication causes the patient to stop is frequently found to exceed by many times that which the patient states. Even under these carefully controlled conditions, Barker, Brown and Roth¹⁴ have found that tissue extracts influence claudication beneficially. Barker has also shown that repeated injections of typhoid vaccine cause improvement in this symptom in about 53 per cent of cases of thrombo-angitis obliterans, however, the results were not checked by the standard test.

In our experience with about 2 000 cases of thrombo-angitis obliterans and thrombo-arteriosclerosis obliterans, healing of indolent ulcers has been observed very commonly without the benefit of passive vascular exercise. These good results have partly been the

result of repeatedly induced vasodilatation, partly the result of rest. The latter is a very important factor. The trauma to feet during ordinary activity is enormous, and no method of treatment can be evaluated truly unless some measuring stick for the beneficial effect of rest is used or unless the patients are ambulatory. Worthy of mention is Samuel's¹⁵ report of twelve cases of gangrene or ulceration in thrombo-angitis obliterans in which healing and relief of pain followed a regimen of rest in bed, cessation of smoking, the intravenous injection of salt solutions, and surgically attained cleanliness. Barker¹⁶ reported excellent to slow healing of ulcers in 86 per cent of cases of thrombo-angitis obliterans, apparently as a result of treatment with artificial induction of fever. The common denominator of many types of treatment is rest in bed, and it is our opinion that this is the most important phase of all successful therapeutic procedures.

Even successful amputation of toes, or of the foot, has been observed on occasions, and the fact that such procedures are successful following passive vascular exercise is not proof of cause and effect unless the percentage of successes is greater than can ordinarily be expected. Such evidence is as yet not available.

The term "collateral circulation" is frequently used in considering chronic occlusive arterial disease. One gains the impression that the term refers to circulation that occurs through newly developed arteries. One of us¹⁷ has reviewed evidence elsewhere that these are not new arteries in an anatomic sense but only in the physiologic sense. In other words, development of collateral circulation is not a process of initiating new arteries to grow in situ but of causing arteries already present to function at a higher physiologic level. Experimental work has indicated that control of the level of function of collateral arteries is largely if not entirely under control of the sympathetic nervous system. An increase in the temperature of the skin is commonly accepted as the best evidence of an increase in the collateral circulation. Sympathectomy remains, then, the best method of increasing circulation through collateral arteries. When sympathectomy is performed, it increases the blood flow to an extremity to an exceptional degree, a result superior to that following any other procedure if degree and permanence are considered together. However, sympathetic neurectomy is inadvisable when gangrene or large ulcers are present.

COMMENT

Evaluation of the results of treatment in medicine is usually difficult, and it is too optimistic to expect any remarkable unanimity of opinion regarding any therapeutic procedure. One thing appears quite certain: the alternate suction and pressure method of treatment has not produced any results that have not been observed repeatedly as a result of simpler methods. Do good results follow passive vascular exercise more frequently than other methods of treatment? We have no answer to this question, and no conclusions can be drawn from reports in medical literature. Do good results follow treatment with intermittent negative and positive pressure in cases in which good results have not or could not reasonably be expected to follow other

methods of treatment? Again no definite answer can be given and none is available in medical literature. Our own opinion is that good results ordinarily follow changing environmental pressure treatment in cases in which good results could be expected from other measures, and that when good results do not follow other measures, passive vascular exercise is usually valueless.

The results of treatment of thrombo-angitis obliterans chiefly by intravenous injection of typhoid vaccine, as reported by Barker, are so excellent that one wonders whether the results of any other single type of treatment can be favorably compared with them. The important question arises: Were the cases of the same general type as those which we have presented in this paper and those which other authors have presented elsewhere? There can be no reliable answer, as the stages and degrees of vascular disease are widely variable. After data have been presented in as extensive a form as advisable, the final resort must be to opinion. Our opinion, based on observation of results of various types of treatment in a large number of cases of occlusive arterial disease, is that the alternate suction and pressure method has been some contribution to the program of treatment. To be sure, this treatment does certain things in peripheral vascular disease, it increases skin temperature and may relieve pain and induce healing of ulcers, but these results follow other methods as well. Evidence is still lacking that passive vascular exercise produces anything other than temporary increases in the circulation. The greatest benefit we have observed from this treatment is in the relief of the pain of ischemic neuritis.

The greatest therapeutic need is a satisfactory method of treating older patients who have occlusive arterial lesions as a result of arteriosclerosis. Such patients do not tolerate well repeated intravenous injections of typhoid vaccine, and the increased risk of sympathectomy, because of their age, ordinarily makes that procedure inadvisable. Moreover, the circulation tends to be diminished progressively, whereas in thrombo-angitis obliterans remissions are not uncommon. It is for such patients that a new procedure is urgently needed. We cannot state as yet that passive vascular exercise is a significant advance in this direction. Objections may reasonably be offered to our results on the basis that patients did not have sufficiently long periods of treatment. We feel, however, that the periods reported are sufficiently long to allow some evaluation of the method.

Our opinion regarding passive vascular exercise is not necessarily final. A revision of this opinion, however, must follow recognition of greater benefit than is available at present. There is need for more specific information regarding the value of the method, and this may be expected as the passage of time allows more extensive observations.

SUMMARY AND CONCLUSIONS

The intermittent suction and pressure treatment of chronic occlusive arterial diseases increases the skin temperature temporarily, may relieve the pain of ischemic neuritis and trophic changes, and may induce healing of ulcers. It is not clear that these results are superior to those following other methods of treatment. However, it is our impression that the pain of ischemic neuritis is relieved to a greater degree than is ordinarily observed. As a result of our experiences we believe that passive vascular exercise constitutes some, but as yet poorly defined, contribution to the treatment of vascular disease.

DIURETIC ACTION OF INTRAVENOUS SODIUM DEHYDROCHOLATE

FRANKLIN A. WEIGAND, M.D.

PHILADELPHIA

Diuresis is obtained in therapeutics by the use of various substances acting through different mechanisms and belonging to different groups. According to their chemical structure and their pharmacologic action, diuretics may be classified as follows: water, the saline diuretics, the xanthines (caffeine, theobromine and theophylline), the digitalis group, mercurial diuretics and finally liver and bile acids.

In the healthy individual with normal water balance, water acts as a diuretic when it is ingested without sodium chloride. Therapeutically this finds use in the restriction of salt intake in the presence of edema, so that water and sodium chloride are eliminated.

The saline diuretics potassium and ammonium salts and urea induce diuresis probably through their osmotic effect. Ingested by mouth, they are most frequently used in conjunction with digitalis or to dilute the urine and decrease its acidity in genito-urinary irritations. Used in large quantities to produce marked diuresis, they cause gastro-intestinal irritation. Urea and the ammonium salts are contraindicated in nitrogen retention.

In the xanthine group, theobromine with sodium salicylate is preferred over caffeine or theophylline. Producing little or no effect on the central nervous system in contrast to caffeine, it is not as irritating to the gastro-intestinal tract as is theophylline. These diuretics are indicated in all cases of edema whether of cardiac, hepatic or renal origin. After prolonged use a certain degree of tolerance is acquired, and in some instances there is discomfort and loss of appetite. They are of most value in nephritis, since these drugs apparently do not injure the kidney even when administered in large doses and for prolonged periods.

The diuresis produced by the digitalis group is due not to direct action on the kidney but indirectly to changes in the circulation. For this reason this group is particularly indicated in cardiac edema and ascites. Squill and digitalis are used together when large accumulations of fluid must be removed. Gastric disturbance and portal congestion interfere with absorption, lessening the efficiency of this group of diuretics. Used in conjunction with the salines or with the theobromine group excellent results are obtained, particularly when the patient is at home where facilities for the use of intravenous diuretics are not readily available.

The diuretic effect of calomel has long been recognized by clinicians,¹ being utilized especially by the combination of calomel with squill and digitalis in a very effective pill used in dropsy of cardiac origin. Parenteral administration of mercury for diuresis is available through the intravenous use of merbaphen and salyrgan. These preparations are particularly indicated in those cases in which absorption through the digestive tract is poor and in which rapid reduction of edema and ascites is desired. Keith, Barner and

Read before the Section on Pharmacology and Therapeutics at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.
¹ Cushny, A. R. A Textbook of Pharmacology and Therapeutics, revised by C. W. Edmunds and J. A. Gunn. Philadelphia: Lea & Febiger, 1928.

Whelan² suggested that their effect may be increased by the oral administration of ammonium chloride. They are contraindicated in the presence of glomerulonephritis, malignant nephrosclerosis, uremia and pre-uremic states, active pulmonary tuberculosis and cachexia.

Since the introduction of liver and liver extract in the treatment of pernicious anemia, the diuretic effect of liver has been reported by numerous observers. In an experimental study of the action of bile, Landau and Held³ noted that diuresis increased when bile was used in cases of renal edema. In their cases (eight of glomerulonephritis and nephrosis, three of cardiac origin) bile was administered orally in the form of cachets or capsules in the dosage of 1 grain (0.06 Gm.) four times daily. Very refractory cases frequently responded with complete disappearance of edema.

SODIUM DEHYDROCHOLATE

The diuretic action of sodium dehydrocholate (sodium decholin) was mentioned by Neubauer⁴ in his original report on the relative nontoxicity of dehydrocholic acid. This bile salt and its acid are not present in either animal or human bile, being formed by oxidizing cholic acid. Comparing the sodium salts of desoxycholic, cholic and dehydrocholic acids, Neubauer found that sodium dehydrocholate had so little hemolytic effect as to be practically nonhemolytic. He found further that dehydrocholic acid was one twenty-fifth as toxic as desoxycholic acid in studies on the isolated frog's heart, and to be tolerated in large doses by the body as a whole, the maximum nonfatal dose being eleven times that of sodium taurocholate and almost a hundred times that of desoxycholic acid. In concluding that dehydrocholic acid and sodium dehydrocholate were strong, safe cholagogues, Neubauer noted the diuretic effect of the sodium salt, commenting on its variability in appearance and its mildness. These preparations were introduced into therapeutics primarily as a cholagogue and cholagogue in 1925 by Adlersberg and Neubauer.

The diuretic effect following intravenous administration of sodium dehydrocholate clinically has been reported by numerous observers⁵. During their study on blood pressure, blood cholesterol and diuresis following ingestion of bile acids, Adlersberg and Taubenhaus⁶ observed an increased urinary output following intravenous injection of sodium dehydrocholate in eight of thirteen cases in their series. Normal individuals as

well as patients with renal or cardiac lesions were present in both groups—those showing diuresis and those failing to show it. These authors concluded that diuresis cannot be predicted in any type of case and that there was no interrelationship between the effect of the drug on blood pressure, blood cholesterol and diuresis. In his studies Semler⁷ found the most marked diuretic effect of this drug in patients with heart disease and a markedly congested liver. Rahmlow and Ritterband⁸ and Lebermann⁹ concurred with this observation, while Bix⁶ made the additional observation that diuresis followed the use of sodium dehydrocholate intravenously in nephrosclerotic edema. Koniger⁵ found the drug to be especially effective as a diuretic in Laënnec's cirrhosis and also reported diuresis after its use in a case of inoperable mesenteric tumor which interfered mechanically with venous return. In one of her cases with marked ascites, sodium dehydrocholate failed to produce diuresis until after the abdomen had been tapped, whereupon a marked diuresis (from 3,600 to 6,000 cc in twenty-four hours) ensued for six days following one injection of sodium dehydrocholate. Variability in the diuretic action of this drug has been noted by all observers.

Combined with Salyrgan—Semler⁵ reported that a brief diuresis from salyrgan could be lengthened by injection of sodium dehydrocholate on the following day. Injecting sodium dehydrocholate one day previously to administering salyrgan, Bix⁶ was able markedly to increase diuresis from the latter. On the basis of these observations Bix was led to attempt administration of salyrgan and sodium dehydrocholate in the same syringe. Diuresis resulting from the injection of 10 cc of 20 per cent sodium dehydrocholate and 1 cc of salyrgan (4,500 cc) was almost twice that from 2 cc of salyrgan alone (2,500 cc). Prohaska⁵ likewise was able to increase diuresis from salyrgan by giving sodium dehydrocholate in the same syringe. Fleckseder,⁷ by adding 20 cc of 33 per cent dextrose to the salyrgan-sodium dehydrocholate mixture, induced daily outputs of 5,000, 6,000, 7,000 and, in one case, 13,500 cc. This combination was just as variable in its diuretic effect as decholin or salyrgan alone. In some of his cases Fleckseder was able to increase the output by the simultaneous oral administration of ammonium chloride.

MODE OF ACTION

Two possible explanations for the diuretic action of sodium dehydrocholate have been advanced. Rahmlow and Ritterband⁸ believe that it may be due to renal irritation, basing their assumption on the observation that jaundice leads to inflammatory changes and that this derivative of a bile acid may act in a similar fashion. Cantarow and Stewart¹⁰ have recently reported a toxic effect on the renal tubular epithelium resembling that of mercury and other tubular poisons in certain animals. Kauftheil and Neubauer⁵ observed an increase in kidney volume lasting as long as the diuresis in the experimental animals being studied. Their oncometric studies revealed a similar enlargement in cases in which the administration of deep narcosis or posterior pituitary lobe extract prevented

the appearance of diuresis after the injection of sodium dehydrocholate. They accordingly concluded that sodium dehydrocholate, despite its marked renal effect, is not the direct diuretic that it seems to be.

THE RÔLE OF THE LIVER

The majority of investigators of the diuretic action of this drug believe that its effect is due to its influence on the liver. Schwiegk,⁹ in experimental studies on dogs, noted a marked increase in the blood supply of the hepatic artery following intravenous administration of sodium dehydrocholate, while the portal vein showed only a small increase. The mixed blood bathing the liver cells accordingly has a greater content of arterial blood and thus the supply of oxygen to the hepatic parenchyma is improved. Schwiegk feels that this arterial hyperemia of the liver is responsible for the influence of sodium dehydrocholate on various functions of the liver, including its influence on diuresis.

MECHANICAL INFLUENCE

The rôle of the liver in water metabolism has been thoroughly expounded by Adlersberg¹⁰ and Villaret.¹¹ These authors are in agreement in assigning a mechanical role in regulating the water economy to the liver. The circulating blood forms but a fraction of the total mass of blood, the remainder being in a stage of relative stagnation as reserves in the different organs and capillary systems. The liver parenchyma is able to store about 1,300 cc of liquid, according to Monneret.¹² Villaret found that injection of colored gelatin into the portal vein of a dog killed by exsanguination was followed in a short time by the appearance of the injected material in the center of the lobule, especially about the central vein. Injection under like conditions into the subhepatic vein results in the appearance of the colored mass in the periphery of the lobule. He states that this phenomenon, disappearing about six hours following death of the animal, is caused by contraction of living parenchyma and illustrates one phase of the mechanical influence of the liver on water metabolism.

In addition to this storage ability, the liver controls the return to the major circulation of all the blood of digestive origin. Mautner and Pick,¹³ while considering the conception of a damlike or barrierlike action in the liver, suggest an autonomic sphincter system about the subhepatic veins. They hold that vagal irritation closes and sympathetic irritation opens this "subhepatic venous dam." The absorption and release of water, according to this conception, is influenced by alterations in the pressure of the hepatic veins. Contraction of the veins increases pressure in the capillaries, water is pressed into the lymph spaces and eventually reaches the thoracic duct. By means of this "overflow pipe" mechanism the liver can supervise the inflow and outflow of water within the blood and tissue circulation. Villaret showed, in dogs, that the introduction of a great mass of water (from two to three times that of the blood) directly into the general circulation was blocked by the energetic action of this barrier.

Adlersberg has studied this mechanism through comparison of the effects of chronic histamine and

chronic phosphorus poisoning experimentally produced in dogs. Led to this procedure by noting the disturbance in water metabolism in certain liver disorders, phosphorus was chosen, since by regulating its dosage hepatic injury can be achieved without cardiac, capillary or renal damage. In the early stages of the poisoning, Adlersberg found increased diuresis following administration of water in contrast to decreased diuresis in the later stages. This resemblance between the changes in chronic histamine and chronic phosphorus poisoning and their analogy with similar changes in certain involvements of the hepatic parenchyma led him to conclude that the same mechanism operates throughout. In the early stages the increased output is possibly connected with the subhepatic venous barrier, under the assumption that this is open, the water would more rapidly flow through the liver. In the later stages, with liver damage, one may assume closure of this barrier mechanism and consequent interference with the flow of water. Villaret likewise emphasizes a vagosympathetic control of the subhepatic venous dam. This has a twofold purpose: (1) an automatic protection for the right side of the heart against irregularities in delivery of return circulation after abnormal increase of the circulatory mass and (2) a protective barrier against heterogeneous proteins.

HORMONIC INFLUENCE

Villaret mentions also the difference between excretion of water injected into the general circulation and that ingested by mouth. Rowntree¹⁴ refers to the observation that the administration of distilled water intravenously is not at once followed by diuresis but that polyuria usually appears in a few hours after the ingestion of water by mouth in excess of from 10 to 15 cc for each kilogram. In attempting to explain the difference in diuresis following water given parenterally and orally, Cow¹⁵ has suggested that in the latter case an enzyme from the alimentary tract comes into play. Glaubach and Molitor,¹⁶ in studying the diuretic action of bile extracts, assign this suggested hormonal role of water regulation on the part of the alimentary tract to the liver. Adlersberg in his exposition of the rôle of the liver in water metabolism stresses this "hormonic" action. In his experiments he found that only when parenterally administered water is infused into a mesenteric vein is its diuretic effect equal to that of swallowed water. He subscribes to the hypothesis that this action may be due to a hormone mixing with the water as it passes through the liver, so affecting it that when it reaches the kidney it is more rapidly excreted.

The explanation of the diuretic effect of sodium dehydrocholate advanced by Adlersberg is based on the belief that it induces a hyperemia of the liver cells, as shown by Schwiegk,⁹ thereby causing more water to be brought under the mechanical and hormonal supervision of the liver. No explanation has been advanced as to why the diuretic effect of this substance is manifested in man only on its use in patients with cardiac decompensation.

The increased diuresis resulting after simultaneous intravenous injection of sodium dehydrocholate and salyrgan in certain cases has been closely studied by Fleckseder.¹⁷ At first he advanced the belief that this

effect may be due to the possible action of sodium dehydrocholate preventing the separation of mercury in the hepatic parenchyma and its subsequent excretion in the bile so that it is returned to the general circulation. More recently he has advanced the belief that there is a special compound formed when sodium dehydrocholate and salyrgan are administered in the same syringe and that this is responsible for the increased diuresis following such administration.

UNTOWARD EFFECTS

Neubauer⁴ and others⁵ have reported the nontoxicity of sodium dehydrocholate. Sterner, Bartle and Lyon¹⁸ observed a temporary hypotension in 50 per cent of their cases, no appreciable change in pulse rate and the occurrence in many cases of a bitter taste a few seconds after the injection was begun. They "believe sodium dehydrocholate can be considered a nontoxic bile salt that can be administered intravenously with reasonable safety." Their views are concurred in by Ziegler,¹⁹ who compared sodium dehydrocholate with other bile salts and concluded that "sodium dehydrocholate is the least toxic of the bile salts and is practically non-hemolytic, being at least 120 times less hemolytic than sodium taurocholate and glycocholate." Rahmlow and Rutterband⁵ in their studies on the diuretic effect of sodium dehydrocholate in man observed no ill effects in the urine after doses as high as 2 Gm. three times a day. All the cases in the series here presented showed more or less albuminuria, which was either uninfluenced or noticeably decreased during treatment.

Sodium dehydrocholate intravenously is contraindicated in mechanical obstruction of the bile passages, acute hepatitis and acute yellow atrophy.

REPORT OF CASES²⁰

CASE 1—A white woman, aged 46, had hypertensive cardiovascular disease, mitral insufficiency with hepatic congestion and edema of the legs. The urine showed a faint trace of albumin, while other laboratory examinations were within normal limits. The daily urinary output was from 500 to 600 cc. before treatment was instituted. Intravenous administration of 10 cc. of 20 per cent sodium dehydrocholate (1 ampule) on three successive days failed to increase the urinary output or reduce the edema. This decreased markedly after the use of Southey's tubes but gradually returned again, the patient leaving the hospital unimproved before further treatment could be instituted.

CASE 2—A white woman, aged 46, had rheumatic heart disease and cardiac decompensation with edema of the ankles. The urine showed a very faint trace of albumin, and other laboratory observations were within normal limits. The daily urinary output varied from 500 to 1,000 cc. Three daily intravenous injections of sodium dehydrocholate resulted in no appreciable difference in the urinary output and the patient left the hospital, unimproved, before further treatment could be instituted.

CASE 3—A white woman, aged 60, complained chiefly of abdominal enlargement on admission. Two months before she had been operated on at another hospital, when a diagnosis of Laennec's cirrhosis was made and omentopexy performed. A faint trace of albumin was found in the urine, no other outstanding laboratory changes being noted. Administration of 10 cc. of 20 per cent sodium dehydrocholate intravenously had no influence on the average daily output of 850 cc. Injection of 0.5 cc. of salyrgan with 10 cc. of 20 per cent sodium dehydrocholate caused an output of 1,850 cc. on the day of

injection and 2,500 cc. on the following day. Repetition of this procedure after the output had fallen to its former level, resulted in a diuresis of 3,500 cc. Two subsequent injections of one ampule of sodium dehydrocholate (10 cc. of 20 per cent solution) and 1 cc. of salyrgan produced no notable increase in diuresis. When discharged, the patient was slightly improved and had lost 5 pounds (2.2 Kg.).

CASE 4—A white man, aged 45, had decompensated rheumatic pancarditis, mitral stenosis, edema and ascites. The heart was uniformly enlarged, with a rough presystolic and systolic murmur over the mitral area, the abdomen showed shifting dullness, the liver border being 5 cm. below the costal margin, there was pitting edema of the sacrum and lower extremities. Laboratory examinations, other than a trace to a very faint trace of albumin in the urine, were not remarkable. The average daily output of urine was from 400 to 600 cc. Three successive daily injections of 10 cc. of 20 per cent sodium dehydrocholate caused no increase in output. Injection of 0.25 cc. of salyrgan produced an output of 1,175 cc., injection of 0.5 cc. of salyrgan with 10 cc. of 20 per cent sodium dehydrocholate resulted in a diuresis of 5,250 cc., while injection of 0.25 cc. of salyrgan with the same amount of sodium dehydrocholate produced an output of 4,050 cc. on one occasion and 1,750 cc. on another.

On discharge this patient had lost 39 pounds (17.7 Kg.) and was markedly improved.

CASE 5—A white woman, aged 54, had arteriosclerotic heart disease with edema and ascites, and diabetes mellitus. The heart was slightly enlarged to the left, the abdomen showed shifting dullness, the liver edge was 6 cm. below the costal margin and pitting edema of both arms and legs was present. While the patient was in the hospital the urine improved from a trace to a faint trace of albumin. Other laboratory observations, with the exception of the hyperglycemia, were not significant. The daily urinary output while the patient was on digitalis and ammonium chloride averaged 600 cc. Three successive injections of 10 cc. of 20 per cent sodium dehydrocholate produced a maximum diuresis of 1,100 cc. On the day following the third injection of sodium dehydrocholate, one injection of 1 cc. of salyrgan was followed by an output of 4,200 cc. Subsequent injections of 1 cc. of salyrgan and 10 cc. of sodium dehydrocholate (20 per cent) resulted in increased diuresis, the maximum result being 2,700 cc. Edema and ascites disappeared, the patient lost 25 pounds (11.3 Kg.) and was markedly improved on discharge.

CASE 6—A man, aged 46, had myocardial degeneration with edema and ascites, hypertension, and acute infectious arthritis. The urine at times showed a very faint trace of albumin, other laboratory observations were not remarkable. The daily urinary output varied from 225 to 800 cc. Intravenous administration of 0.5 cc. of merbaphen was followed by a diuresis during the ensuing five days of 7,570 cc., the highest daily output being 2,350 cc. on the fourth day after injection. The output fell to 250 cc. and subsequent injection, on three successive days, of 10 cc. of 20 per cent sodium dehydrocholate resulted in an output of 11,615 cc. for five days, the highest daily output of 3,250 cc., which occurred on the fifth day, two days after the third injection of the drug. In this case the output of 11,615 cc. following the use of the relatively nontoxic sodium dehydrocholate compares favorably with that of 7,570 cc. after the use of merbaphen. On discharge this patient was markedly improved and had lost 41 pounds (18.6 Kg.).

CASE 7—A white man, aged 46, had chronic glomerulonephritis, myocarditis with edema and ascites. The heart was moderately enlarged, a definite fluid wave was determined in the abdomen (the liver margin was not felt) and there was marked edema of the lower extremities. Other than a lessening of albuminuria from a dark cloud to a cloud and a phenol-sulfonphthalein output of 40 per cent, laboratory observations were not significant. The daily urinary output of 450 cc. was raised to 1,225 by administration of digitalis and ammonium chloride. Intravenous injection of 10 cc. of 20 per cent sodium dehydrocholate resulted in the output of 2,300 and 1,800 cc., on the first and second days following injection. A second injection of this drug resulted in an output for two days of 1,675 and 2,475 cc. Later injections of sodium dehydrocholate resulted in increased output, the greatest being 3,275 cc.

¹⁹ Ziegler E. E. Sodium Dehydrocholate—Its Specific Effect on Pneumococci. *J Lab & Clin Med* 18: 868 (June) 1931.

²⁰ These cases were seen in the ward service of Dr. Edward L. Bortz at Lankenau Hospital.

On discharge this patient was markedly improved, the edema had subsided and he had lost 27 pounds (12 Kg.)

CASE 8—A Negro man, aged 47, had syphilitic myocarditis, decompensation with edema and ascites. Noteworthy on physical examination was the presence of pitting edema of the legs, with involvement of the penis and scrotum, the abdomen was distended, with a fluid wave and shifting dullness, the liver being enlarged to the umbilicus. The heart sounds were of poor quality. The Wassermann and Kahn reactions were four plus; the urine showed variable amounts of albumin and other examinations were not unusual. The daily urinary output averaged 500 cc. Injection of 10 cc. of 20 per cent sodium dehydrocholate raised this to 1,100 cc., repetition of this dose with 0.5 cc. of salyrgan gave a maximum output of 2,650 cc. on the day following injection, the daily average being above

TABLE 1—Maximum Output and Weight Before and After Treatment and Total Number of Injections

| Case | Diagnosis | Maxi- mum Output Before (in Cc.) | Maxi- mum Output After | Weight Before (Lbs.) | Weight After | Total Num- ber of Injections |

baphen S½ ½ 1 = 0.25, 0.5 cc. of salyrgan

* Dosage causing maximum output

1,500 cc. for the ensuing five days. At the end of this time the edema and ascites were gone and the patient had lost 26½ pounds (12 Kg.)

CASE 9—A white woman, aged 67, had decompensated arteriosclerotic heart disease with edema and ascites. Positive physical changes were slight cardiac enlargement, a palpable liver border, fluid wave in the abdomen, and pitting edema of the lower extremities. Albumin was present in the urine, varying from a trace on admission to a very faint trace on discharge. Other laboratory observations being not remarkable. Ten cubic centimeters of 20 per cent sodium dehydrocholate and 1 cc. of salyrgan administered simultaneously resulted in an output of 7,200 and 2,150 cc. on the two days following administration. Injection of sodium dehydrocholate alone, on two separate occasions, resulted in an output of 1,750 cc. and 1,235 cc. respectively, compared with the daily average output of from 300 to 500 cc. before treatment was instituted. The edema having subsided subsequent injections of sodium dehydrocholate and salyrgan in combination and of salyrgan alone, produced no diuresis. On discharge the patient had lost 17 pounds (7.7 Kg.) had no edema and was markedly improved.

CASE 10—A white man, aged 61, had decompensated rheumatic myocarditis, mitral stenosis, edema and ascites. On physical examination there was marked cardiac enlargement, a mitral systolic murmur, marked enlargement of the liver, shifting dullness with fluid in the abdomen, and marked edema of the lower extremities. The daily urinary output averaged from 350 to 500 cc. There was a variable albuminuria (faint to a very faint trace) throughout treatment, and other laboratory observations were not remarkable. Numerous injections of sodium dehydrocholate and salyrgan, alone and in various combinations, were given. Of the eleven injections of sodium dehydrocholate alone (10 cc. of 20 per cent solution) five injections produced no increased diuresis. The highest output from this drug occurring one day after the injection was 2,925 cc. The greatest output from salyrgan alone followed injection of 2 cc., a total output of 7,700 cc. (2,125 and 5,575) ensuing on the two following days. The greatest diuresis of the entire series of this patient's injections, 7,275 cc. on the day of injection and 3,175 cc. on the following day, a total of 10,450, followed injection of 0.5 cc. of salyrgan and 10 cc. of 20 per cent sodium dehydrocholate. The patient's weight was reduced 98 pounds (44.5 Kg.), the ascites was eliminated and the edema was markedly reduced. The inevitable tendency to recurrence of the edema necessitates effective diuresis every six or seven days.

CASE 11—A white woman, aged 35, had decompensated rheumatic pancarditis with edema, auricular fibrillation and asthma. The patient entered the hospital in collapse. The heart and liver were both markedly enlarged, numerous asthmatic and moist rales were heard throughout the chest and the lower extremities were markedly edematous. Albuminuria improved from a cloud to a very faint trace during her stay in the hospital. Other laboratory observations were not remarkable. The daily urinary output averaged 500 cc. Three daily injections of 10 cc. of 20 per cent sodium dehydrocholate produced a maximum output of 1,050 cc., 0.5 cc. of salyrgan administered on two successive days resulted in an output of 1,025 and 1,775 cc., 2 cc. of salyrgan at one time produced an output of 1,030 and 1,135 cc., on another occasion the same amount caused an output of 1,000 and 2,955. Injection of 10 cc. of 20 per cent sodium dehydrocholate and 2 cc. of salyrgan together was followed by an output of 1,500 and 1,900 cc. on one occasion and on another by output of 1,225 and 2,190 cc. Weight had decreased 35½ pounds (16 Kg.), the edema had disappeared and the patient was markedly improved on her discharge.

CASE 12—A white man, aged 60, had hypertensive arteriosclerotic cardiovascular disease with edema and ascites. There was a moderately enlarged heart, fluid wave and shifting dullness in the abdomen, and marked edema of the lower extremities. Urinalysis showed a faint to a very faint trace of albumin during treatment, while other laboratory observations were not remarkable. The daily output was 500 cc. Injection of 10 cc. of 20 per cent sodium dehydrocholate and 0.5 cc. of salyrgan resulted in an output of 2,575, 1,875 and 1,230 cc. on three successive days, the output falling to 500 cc. thereafter. A second injection of the same dosage of both drugs was followed by an output of 2,475 cc. two days after the injection, a third injection resulted in an output of 1,525 and 2,500 cc. on the following days. The patient lost 25 pounds (11.3 Kg.), edema and ascites disappeared, and on discharge from the hospital he was markedly improved.

SUMMARY

Cases 1 to 4 showed no increase in diuresis following intravenous administration of sodium dehydrocholate alone. Cases 3, 4 and 5 responded variously to subsequent administration of different amounts of salyrgan in combination with 10 cc. of 20 per cent sodium dehydrocholate, the markedly increased diuresis obtained in case 4 suggesting that the dose of salyrgan can be markedly reduced by this combination.

Marked diuresis followed intravenous injection of sodium dehydrocholate in cases 6 and 7.

Fair diuresis followed the use of sodium dehydrocholate in cases 8 to 11 inclusive. Combination of

varying amounts of salyrgan with 10 cc of 20 per cent sodium dehydrocholate resulted in marked diuresis in cases 8 to 12, results in cases 9, 10 and 12 again suggesting that the dose of salyrgan can be markedly decreased by combination with sodium dehydrocholate.

Table 1 summarizes salient data on the twelve cases here presented. Typical variability in response to sodium dehydrocholate and salyrgan, alone and in combination, is shown in table 2.

COMMENT

With the exception of one case (Laënnec's cirrhosis) all cases in this series presented edema or edema and ascites accompanying myocardial disease and hepatic congestion. It is for this type of case that the diuretic action of sodium dehydrocholate has been especially suggested.

In four of the eleven cases in which sodium dehydrocholate alone was used, no increased diuresis was observed (cases 1 to 4). Cases 5 to 11 inclusive showed an increased diuresis after sodium dehydrocholate intravenously, cases 6 and 7 being particularly marked. Results in eight cases (3, 4, 5, 8, 9, 10, 11 and 12) showed the most effective diuresis after simultaneous injection of varying amounts of salyrgan.

TABLE 2—Variability in Diuretic Response

| Case | | First 24 Hours Cc | Second 24 Hours Cc | Total 48 Hours Cc |
|------|--------------------|-------------------------|--------------------------|-------------------------|
| 4 | 0.25 cc S | 1 175 | 0.0 | 1 175 |
| | 10 cc. D | 6.0 | 57.0 | 1 222 |
| | 0.25 cc S 10 cc. D | 1 750 | 1 12.0 | 2 875 |
| | 0.25 cc S 10 cc. D | 4 000 | 1 0.0 | 5 100 |
| | 0.5 cc S 10 cc. D | 4 550 | 700 | 5 250 |
| 10 | 10 cc. D | 0.0 | 1 550 | 2 450 |
| | 10 cc. D | 2 02.0 | 1 500 | 4 42.0 |
| | 10 cc. D | 825 | 625 | 1 550 |
| | 1 cc S | 1 875 | 5 775 | 7 650 |
| | 2 cc. S | 2 12.0 | 5 576 | 7 700 |
| | 0.5 cc S 10 cc. D | 7 275 | 8 175 | 10 450 |
| | 1 cc. S 10 cc. D | 1 300 | 6 7.6 | 7 075 |

S = salyrgan D = sodium dehydrocholate

with 10 cc of 20 per cent sodium dehydrocholate. In six of these cases (3, 4, 8, 9, 10 and 12) the maximum output followed administration of 1 cc or less of salyrgan in combination with sodium dehydrocholate, a result comparing very favorably with that reported by Fleckseder,¹⁷ Bir,⁵ and others, when 1 cc or more of salyrgan was used in this combination.

In the three cases in which ammonium chloride was used, no marked increase in diuresis was observed. It was impossible to predict just how any given case would respond to any of the doses and combinations used, the variability in diuresis following intravenous injection of sodium dehydrocholate observed by Adlersberg and Taubenhaus,⁶ Koniger⁸ and others being confirmed by our observations.

CONCLUSIONS

1 A series of twelve patients were given 10 cc of sodium dehydrocholate intravenously, alone and in combination with salyrgan, in order to determine the resultant diuretic effect.

2 Three patients showing no diuretic effect from the bile salt and five more showing moderate diuresis from its action all experienced marked diuresis when given this bile salt combined with salyrgan.

3 Four other patients were not given this combination but the bile salt alone. Two of them showed a good response and two failed to respond at all.

4 This small series suggests that, while sodium dehydrocholate has some diuretic effect, it becomes a

satisfactory diuretic in most cases only when combined with salyrgan. The effective dosage of the mercurial diuretic salyrgan seemed to be considerably lower when used in this combination.

Sixteenth and Jefferson streets

ABSTRACT OF DISCUSSION

DR. B. B. VINCENT LYON, Philadelphia. After six years of experimental work with sodium dehydrocholate in Germany and France, and after the bibliography of published papers had exceeded 100, it was introduced into America. In 1929 Wakefield, Powelson and McVicar of the Mayo Clinic studied and reported favorably on its choleretic action. In 1931 Sterner, Bartle and I studied and reported favorably on its cholegogic action. In 1932 Jenkelson and Altman used it to enhance the value of cholecystography. In 1934 Swalm, Bartle, Sterner and I published a report of a two year clinical study of its therapeutic effectiveness in sixty cases of various diseases and disorders of the liver and concluded that its exhibition alone or preferably combined with other measures might be considered helpful. Since then I have used it extensively in the tablet form (dehydrocholic acid) and to lesser extent by vein (sodium dehydrocholate) in a large number of disorders of the liver, and I feel that it has helped the patients beyond question, although the extent of its benefits is somewhat variable. Its effectiveness is increased when given by vein and I no longer have fear of using 10 cc of the 20 per cent solution. I have had no experience with it in the dropsy of cardiovascular-renal diseases, except when the liver has been enlarged by chronic passive congestion or when there was associated hepatic ascites. Although not invariably successful it has usually helped me, and I have as yet seen no harmful results from its use. Cantarow and Stewart have recently noted a toxic effect on the kidneys of certain experimental animals following the use of this drug. Last spring Shay, Fitzhugh and Raydin, before the Philadelphia College of Physicians gave a preliminary report on their favorable impressions from its use in biliary migraine and several forms of so-called allergic diseases. I am satisfied that it has helped the majority of my cases classified as biliary migraine, but I have had no personal experience with it in allergic diseases. In our clinical study of sixty cases of disorders of the liver in which the drug was given chiefly by mouth in tablet form, we were able to note a diuretic effect of slight degree in only five cases. On the other hand, there was a marked increase in the amount of bile flow from the liver to the intestine, which helped to combat constipation and in some cases produced a definite bile irritation diarrhea. When one is confronted with a single drug that seems to act favorably in such a wide variety of diseases and disorders, one necessarily becomes cautiously skeptical. Nevertheless I feel that this particular bile salt acid is a useful and safe drug.

DR. ABRAHAM CANTAROW, Philadelphia. In our studies of the biliary tract of cats, Stewart and I have observed the effects of the intravenous injection of sodium dehydrocholate. Observations were made on thirty cats with ligation of the common duct and on twenty normal adult cats. From one to sixteen daily injections were given, the amount administered being 0.2 cc. of a 20 per cent solution. The animals were killed by bleeding under light ether anesthesia twenty-four hours after the last injection. Striking changes were noted in the renal tubular epithelium in every case, being as marked in the normal animals as in those with biliary stasis. The cells of both convoluted and Henle's tubules showed all stages of epithelial degeneration and necrosis from simple hydropic swelling to complete denudation of the basement membrane. Active regeneration occurred rapidly with the production of an atypical, flattened type of epithelium described by MacNider, Oliver and others, in animals receiving various nephrotoxic substances. This type of epithelial change was present to some degree after a single injection but was most conspicuous after from two to six injections. As the number of injections increased, the lining cells of the tubules increased in height, becoming cuboidal and later columnar in type. The impression was obtained that the atypical, flattened cells, regarded by most observers as highly resistant to subsequent injury gradually developed into the

cuboidal and columnar cells. These, too, were apparently more resistant to injury than the normal cells. Mitotic figures were seen at all stages, being particularly numerous after from three to seven injections. Similar changes were noted in animals in which a single injection was made into the portal vein. Non-protein nitrogen values as high as 148 mg per hundred cubic centimeters of blood were obtained after a single injection, the highest figure obtained subsequently being 67 mg per hundred cubic centimeters. On the basis of these observations it appears that sodium dehydrocholate is highly nephrotoxic for the cat. Other species may differ, but the characteristic localization of the lesion suggests that it may bear some causal relation to the diuretic action of this substance. The fact that diuresis occurs almost exclusively in patients with liver functional impairment may be dependent on diversion of the excretion of this substance from the liver to the kidneys under such circumstances.

DR. FRANKLIN A. WEIGAND, Philadelphia. It is rather odd that Kaufheil and Neubauer did not complete the observation made when they noted gross changes in the kidney, by studying it microscopically. However, Rahmlow and Ritterband have studied the effect of sodium dehydrocholate on the kidney and have found no ill effects in the urine after using as much as 2 Gm. of the drug three times a day. In my cases either those that presented albuminuria showed no increase in albuminuria or it was definitely decreased during the course of treatment.

THE INTRADERMAL REACTION FOR CHANCROIDS WITH CHAN- CROIDAL BUBO PUS

H. N. COLE, MD

AND

E. A. LEVIN, MD

CLEVELAND

In 1913 Ito, working with Carl Bruck at Neisser's clinic, devised a specific intradermal test for chancroid—Ducrey bacillus infection. The diagnostic value of this test was later confirmed by Reenstierna, working with a serum containing antibodies of the Ducrey bacillus. Today this test is spoken of as the Ito-Reenstierna reaction.

Ito, for his cultures, used 24 hours old streptobacillus colonies from two Besançon blood agar tubes. The bacilli are suspended in physiologic solution of sodium chloride with the addition of 0.5 per cent phenol and heated at 60 C for two hours. Reenstierna employed unheated material in the presence of phenol for fourteen days in the icebox. Frei¹ in his survey of the entire subject up to 1927 says that he employed the water of condensation. He also states that it makes little difference what method of preparation is employed.

The antigen is employed as an intradermal test, readings being made in forty-eight hours, the same as in the tuberculin reaction. The reaction will generally show positivity within from eight to twelve days after the infection,² being dependent on the virulence of the organism, on the length of the infection and on the course of the disease. In a recent study Lippert³ states his belief that uncomplicated chancroidal infections will give a negative reaction unless there is extensive destruc-

tion. With beginning bubo the test may be negative. If ulcers are old, even with no bubo, the test may be positive, and with extensive broken down bubo it is practically always positive. The reaction is more likely to be positive after the lymph nodes are involved. The reaction is specific with less than 1 per cent nonspecific reactions⁴ and persists at least for twenty-five to forty years, even fifty years in a case of Reenstierna.¹ In the recent symposium of the French Dermatologic Society on chancroid, held at Strasbourg, there was a surprising unanimity of opinion as to the specificity of the test. In European clinics an antigen, dmecos vaccine, elaborated according to the method of Nicolle and Durand, is quite generally employed. This preparation is a mixture of the killed streptobacillus in suspension and of an antibody containing serum elaborated according to the technic of Reenstierna. It is used not only for diagnostic purposes but also for therapy, either intramuscularly or intravenously in rapidly ascending doses. Generally a few doses suffice to check the disease.

In the United States it is impossible to procure this agent because of certain public health regulations. Moreover, despite numerous attempts to prepare our own antigen, it has been found most difficult to grow the streptobacillus of Ducrey. Thus the need for a simple diagnostic test for this disease is obvious.

As long ago as 1923 Bordin and Turpin⁵ distinguished between what they spoke of as "septic" and "aseptic" pus—i.e., sterilized and nonsterilized pus—and mentioned their use in veterinary medicine. They felt that it had some resemblance to protein therapy. Fay and Gaal⁶ treated a series of cases of chancroid by simply withdrawing 1 cc of pus from a chancroidal bubo and injecting it, without sterilization, subcutaneously into the buttock. It was termed "pyotherapie." Injections were given every four to five days. Later they employed doses of 0.25 cc up to 1 cc, increasing 0.25 cc at a time. There was no infection and the results were very good. Cruveilhier,⁷ also in 1922 after subcutaneous injections of autogenous pus (heated at 57 C for one-half hour) had noted good and rapid effects on soft chancre infection, and in 1926 Vigne, Fournier and Acquaviva⁸ used boiled milk injections for treating chancroidal bubo and also "pyotherapie." They employed 1 cc of pus plus 20 cc of saline solution put up in 1 cc capsules and sterilized at 56 C for one hour. They injected the material in ascending doses, 0.25, 0.5, 0.75 up to 1 cc, intramuscularly every two to three days. Thirty cases were treated. It was noted that after the first injection pain disappeared. The edema of the lymph node went down and hospitalization was shortened. In two cases there was no response. Frei was not sure whether this was a vaccine treatment or a special form of protein therapy. He suggested that this might be settled by using chancroidal pus for intracutaneous tests as in lymphogranuloma inguinale. Annuzzi⁹ compared tests made with this specific bubonic pus with the Nicolle and Durand vaccine and found the results to be comparable, though perhaps weaker and more transitory after intradermal injections of sterilized pus. Nicolas, Lebeuf and Weigert¹⁰ confirmed the comparable character of the two antigens, and Bizzo-

zero, in discussion, said that in one case inoculated with this specific sterilized pus a bulla formed, the serum from which, inoculated in the same patient, caused the appearance of a characteristic papular intracutaneous reaction. Nicolas and Lacassagne¹¹ went still further and took a group of patients and infected them with the bacillus of Ducrey. They then did a series of intradermal tests with the chancroidal sterilized pus, making tests every two days. In eight cases they found positive tests after from six to eight days. Bratzlavsky and Marenus¹² tested out ninety-nine cases, using the pus antigen according to the technic described by Frei. There were thirty-three cases of uncomplicated chancroid and nine with buboes. There were five cases with histories of previous soft chancres and fifty-two other control cases but with no history of chancroids. In 81 per cent of the chancroidal cases there were positive reactions. Among the fifty-two controls the reactions were negative except in two cases presenting indefinite histories and primary syphilis. Franchi¹³ employed the sterilized serum aspirated from the surface of soft chancres as an intradermal antigen. It likewise gave specific reactions. Jersild¹⁴ has also studied the problem and confirmed the fact that, whether sterilized or unsterilized pus from a chancroidal bubo was used as an intradermal antigen, it would give positive reactions in chancroidal cases.

INVESTIGATIONS

Stimulated by these facts and because of the great need of further diagnostic help in certain moot cases of Ducrey bacillus infection, it was decided to investigate this problem further. Also, we were aware of the frequent suspected cases in which it was impossible to find the bacillus of Ducrey either in the original ulcers or in the auto-inoculations so much employed in the European clinics¹⁵ because of greater ease in finding the Ducrey organisms in the fresh secondary lesions.

PREPARATION OF ANTIGEN AND DESCRIPTION OF TEST

The antigen for the intracutaneous chancroidal test is prepared from a proved chancroidal bubo, i. e., one in which the bacillus of Ducrey can be demonstrated either in the primary lesion or in the pus present in the bubo. The patient from whom the material is obtained must have a negative Frei reaction and the antigen prepared must react negatively in patients with proved lymphogranuloma inguinale.

The pus aspirated from a suppurating unruptured node is diluted with five parts of physiologic solution of sodium chloride and then heated at 60 cc for two hours and repeated for one hour the following day. The material is then tested for sterility.

The test itself is simple to perform and is similar to the tuberculin or Frei test. One-tenth cubic centimeter of antigen is inoculated intracutaneously and the results are read in forty-eight hours as negative to four plus, depending on the degree and severity of the reaction. A positive test presents itself as an infiltrated, rounded papule with a base from 0.5 to 1 cc in diameter. When the reaction is marked, the induration is much larger and may even go on to necrosis.

NUMBER OF TESTS PERFORMED AND RESULTS

From Nov. 10, 1934, to March 19, 1935, 433 intracutaneous chancroidal tests were performed on different subjects, all patients in the Cleveland City Hospital. In fifty-two cases the test was found to be definitely positive and in 272 negative. The remaining 109 were repeat tests, either negative or positive. The fifty-two positive cases can be conveniently divided into four groups.

Group A. Patients studied during the active manifestations of the disease.

Group B. Patients with old known previous chancroidal infection.

Group C. Patients with histories of previous venereal ulcerations and suppurating buboes.

Group D. Patients without active infection or history of such in the past.

Group A is composed of twenty-two patients, twenty-one male and one female. In fourteen of these the bacillus of Ducrey was demonstrated in the primary lesions. The remaining eight cases were diagnosed by the typical chancroidal ulceration and at times bubo formation plus a positive intracutaneous test.

Group B consists of five patients in whom a previous hospital record showed the clinical diagnosis substantiated by the presence of the bacillus of Ducrey. The test was found positive three years after the infection in two of these patients and six months after the infection in the remaining three.

In group C there are twenty patients in whom the test was positive without any active manifestation of the disease. All were males and had a history either of previous genital ulceration or of previous suppurating bubo. The lapse of time between infection and positive reaction in seven of these twenty cases was from three to nine years. Nine patients gave a history of infection for from ten to twenty-four years and four a duration of from thirty to thirty-four years. It is interesting to observe that in this entire group of twenty patients fifteen, or 75 per cent, had a recent or old syphilis. In addition seven, or 35 per cent, had a positive Frei test. Of these seven, one was an active case of lymphogranuloma inguinale and the other six either had a history of bubo in the past or inguinal scars were noted.

Group D consists of five patients. These will be considered under possible "false positive tests."

CONTROL CASES

In relation to other venereal diseases the test was found negative in ten cases of lymphogranuloma inguinale, twenty-two primary syphilitic lesions, twenty-seven active secondary syphilitic cases, thirty-seven presenting latent or central nervous system syphilis, nine cases of acute gonorrhea and two presenting granuloma inguinale. In the remaining negative tests there were fifty cases of pulmonary tuberculosis, twenty-six in all stages of pregnancy, thirty-five presenting various skin diseases, including mycotic infections, and a miscellaneous group of fifty-four, chiefly from the medical wards.

DURATION OF ULCERATION AND RUBO IN RELATION TO TEST

In patients in whom the test was negative on entry and gradually became positive, the increased positivity could readily be followed by repeated weekly tests. Nine patients in group A showed a negative intracutaneous test on admission and subsequently became positive. The interval from the onset of the primary lesion to the first positive test varied from five to nine weeks, with an average of seven weeks.

¹¹ Nicolas J. and Lacassagne J. Bull. Soc. franç. de dermat. et syph. 35: 753 (July) 1928.

¹² Bratzlavsky and Marenus. Russk. Dermat. 7: 243 1929. abstr. Zentralbl. f. Haut u. Geschlechtskr. 31: 147 1929.

¹³ Franchi F. Bull. Sez. region. Soc. ital. Derm. 5: 315 1931. abstr. Zentralbl. f. Haut u. Geschlechtskr. 40: 417 1932.

¹⁴ Jersild O. Hospitalstid. 74: 883 (Sept. 3) 1931. abstr. Zentralbl. f. Haut u. Geschlechtskr. 33: 841 1935.

¹⁵ Ravaut, P., and Rabreau H. Bull. Soc. franç. de dermat. et syph. 37: 593 1910.

Of these nine patients, four had involvement of the inguinal nodes. The interval from the onset of the bubo to the first positive test varied from four to five weeks. In the remaining thirteen patients of group A the test was positive on admission. The duration of the latent period from the development of positivity could not, of course, be observed. The primary lesion had been present (based entirely on the history of the patient and not on hospital observation) from one to seven weeks, with an average of four weeks. In nine of these the lymph node involvement had been present from two to five weeks, with an average of three weeks.

Considering, then, the entire group of twenty-two patients (one female, twenty-one male) the average latent period from the presence of the primary ulcer to the first positive test was five weeks and from the appearance of the bubo three weeks.

Chancroidal ulcer of Frenulum. Bubo and positive intradermal tests on forearm with three different antigens

In two patients, one male and one female, with proved active chancroidal infection without bubo formation, the test remained negative six weeks and seven weeks, respectively, after the lesion appeared. Further follow-up tests could not be obtained. Since in two cases of group A with active chancroidal infection the test did not become positive until after eight and nine weeks, these two patients giving negative tests can be considered only as not being followed sufficiently long.

RELATION OF TEST TO BACILLUS OF DUCREY, ULCER AND BUBO

At first glance there seemed to be no close relationship between the degree of the reaction in the intradermal test and (1) the presence or absence of the bacillus of Ducrey and (2) the extent and type of primary lesion.

Thus in the eight patients in whom the bacillus of Ducrey could not be demonstrated in the ulcers after careful search, the skin reaction in seven was strongly

positive and in the remaining case only weakly so. In the fourteen patients with positive smears the test was strongly positive in eight and only moderately or weakly positive in six. While this is not a large series, it would, however, tend to show only moderate relationship between the abundance of organisms and the degree of positivity of the test.

It would seem that the greater the tissue involvement the stronger the reaction to the test. An analysis of the material failed to bring this out. In eight patients in whom the skin involvement was minimal, i. e., one or two lesions with a total area of about 1 sq cm or less, the reaction was mild in three, moderate in two and strong in three. In seven cases in which the skin involvement was between 1 and 2 sq cm the reaction was mild in three, moderate in three and strong in one. In the remaining six patients in whom the skin involvement was extensive the test was noted as mild in three, moderate in two and strong in only one. In the only female in this group suffering from an adenitis but with no primary lesion, the test was strongly positive.

It might be stated here that patients in groups B and C, in whom the reaction was positive without active disease, with only a past history, similarly gave varying degrees of positivity to the test. Eleven were noted as strongly positive, while the remaining fourteen were only moderately so.

As to the effect of bubo formation on the skin allergy, it was found that in thirteen patients of group A with buboes the test was strongly positive in twelve and only weakly positive in one. Bubo formation tends to induce a strong allergy. Of the remaining nine patients without lymph node involvement, three gave a strong reaction and six reacted only moderately.

Three patients had negative intracutaneous tests on the day on which pus was aspirated, but the pus made an active antigen. All three subsequently, from eight to ten days later, gave a positive skin test. Another patient, while yielding pus with strongly antigenic properties, reacted weakly to other potent antigens. Auto-inoculation in one with a weakly positive test did not appear to raise the allergic reaction to the test.

In using normal patients as controls, no instance has been observed in which the specific allergy of the skin has been raised by the intracutaneous test, despite the fact that repeated tests have been made on the same patients.

POSSIBLE FALSE POSITIVE TESTS

There were five patients in group D, three males and two females, who gave a positive intradermal test yet had no active lesions and gave no history of previous venereal ulceration or of suppurating bubo. Of the females, one had a history of gonorrhea nine years before and the other had a positive blood Wassermann reaction. One of the men had an active lymphogranuloma inguinale, one a positive blood Wassermann reaction, and the other a history of gonorrheal urethritis in the past. The diagnosis is given in each case to emphasize the fact that venereal disease was common to this group, and a chancroidal infection in the past would not be unusual for these patients, even though denied by the history. Consequently we are inclined to accept the intradermal reaction as evidence of old submerged chancroidal infection.

COMPARISON OF DMELCOS AND PUS ANTIGEN

In the last few weeks of this investigation a small amount of dmelcos vaccine was obtained.¹⁶ A number

¹⁶ We are indebted to Dr. Marion B. Sulzberger of New York for the supply of dmelcos vaccine.

of tests were done simultaneously with the other tests, the diluted chancroidal pus being used. In no instance was there any discrepancy noted, i. e., a positive dmelcos vaccine always gave a positive test with the chancroidal antigen, similarly, a negative chancroidal antigen test gave a negative dmelcos test. It was noted, however, that the dmelcos antigen gave a more clear-cut and stronger reaction.

COMMENT

This study seems to confirm the observations of previous workers as to the specificity of an antigen prepared from the pus of chancroidal buboes and used as an intradermal diagnostic test. This test, like the Frei test, is probably to be attributed to the presence in the pus of the causative factor of the disease, perhaps specific antibodies in the pus may also play a role. At any rate, the reaction to dmelcos vaccine would point to these two probabilities. The test, in our experience, is quite specific and in the hands of careful workers, with plenty of material, will undoubtedly be of great value in diagnosing certain suspected chancroidal infections in which organisms cannot be found. Apparently the allergic powers in the human body caused by a chancroidal infection, once they are developed, persist to a certain extent throughout life. Naturally, in performing the test, antigen prepared from a certain patient's chancroidal bubo should not be used for diagnostic purposes on that patient.

SUMMARY

1 The use of an intradermal diagnostic test, with sterilized pus from chancroidal buboes, confirms the specificity of the test in cases of Ducrey bacillus infection and corroborates the observations of earlier workers.

2 The interval from the presence of the ulceration to the production of a positive test was on the average five weeks.

3 The presence of a chancroidal bubo seems to increase the rapidity and the intensity of the intracutaneous test.

4 The allergic properties raised in a patient by a chancroidal infection persist for years, in our experience at least from thirty to thirty-four years.

ABSTRACT OF DISCUSSION

DR. EUGENE F. TRAUB, New York. In the past the dermatologist had but few laboratory tests to help him to differentiate between the skin lesions of two or more diseases that might often closely approximate one another. Cutaneous tests are now commonly employed in tuberculosis, dermatophytosis, inguinal lymphogranuloma and chancroids. Because of the larger number of persons who have at some time been infected with tuberculosis or tinea, the skin tests in these diseases must be carefully weighed before they are given any diagnostic significance. In the case of inguinal lymphogranuloma the Frei test is specific and diagnostic. Drs. Cole and Levin have now reported definite confirmation of the observations of previous workers as to the specificity of the intradermal test for chancroids, using chancroidal bubo pus as an antigen. The use of this method raises several pertinent points in view of the fact that the dmelcos antigen has been found uniformly satisfactory, however, it cannot be obtained legally in the United States. The only reason for searching for another test is the difficulty in obtaining the dmelcos vaccine and the difficulty in growing the Ducrey bacillus. I should like to ask the authors why we have this difficulty in growing the organism, because recently at an academy meeting some men believed that the organism could be grown rather easily and others maintained that it could not. Human pus was originally used in the Frei test. It was impossible in this way to get a preparation that could be standardized.

This was all rectified when Levaditi, Pavant and Schoen in 1932 showed that the brains of mice could be infected, and thus opened a source of antigen, Grace and Suskind, of a measured and graded amount of uniform potency and quality. Such a supply is unlimited. Does it not seem logical, therefore, that in the chancroidal test we shall eventually strive to get away from the use of human pus? In the meantime, the test under consideration offers a valuable temporary aid. Both tests, the dmelcos and the present one, parallel each other in the period of time at which the tests become positive, the length of time the patient reacts positively, from 25 to 40 years, and so on. But the dmelcos vaccine gives a sharper and more clean-cut reaction. It is interesting that only a moderate relationship existed between the abundance of organisms and the degree of positivity of the test. In the work in which I engaged with trichophyton, the culturing of an organism from the skin or nails was not even necessarily accompanied by a positive skin test. When extensive or acute "ids" were present, the majority of the cases gave generally moderately strong positive reactions, but the strong allergy produced by bubo formation was not so evident in cases of dermatophytosis with "ids."

DR. DAVID BLOOM, New York. Until now this method of identifying Ducrey infection was not used much in this country by others or myself at the Dermatology Department of Dr. Fox. The reason was that we were concerned particularly in distinguishing between buboes due to lymphogranuloma infection virus and ulcer molle buboes. We were concerned in convincing others and also ourselves of the existence of inguinal lymphogranuloma buboes. In this we could succeed only by using the Frei antigen, which consists of sterilized pus from those gland tumors which looked clinically like inguinal lymphogranuloma, or a test substance which represents with certainty Ducrey infection, and this is the dmelcos vaccine, a suspension of streptobacilli. This dmelcos vaccine is not manufactured here and for some reason is not permitted to be brought into this country. In the near future, however, this vaccine will be manufactured here and we shall not have to embarrass our Canadian friends by asking them to supply us with the vaccine. Now that we are convinced of the existence of inguinal lymphogranuloma buboes and are able in the great majority of cases to make the diagnosis clinically, the method of testing reported by Drs. Cole and Levin will be of great additional value, of lower value, however, than the streptobacillus vaccine itself. In the same way will the Frei antigen, as prepared until now, lose in value, should we succeed in the future in isolating the lymphogranuloma infection virus itself.

DR. JAMES L. PIPKIN, San Antonio, Texas. During the last five years I have done 1,200 Frei tests, obtaining about sixty positive reactions. I felt that there was an overlapping in these adenitis cases which were giving positive reactions with the prepared antigen. After some difficulty I was able to obtain some dmelcos vaccine from Dr. Williamson in Canada. I rechecked a number of the positively reacting patients who had given conflicting readings. I want to speak for the specificity of dmelcos vaccine and the sterile chancroidal pus. I was able to get positive reactions in the questionable cases by using the chancroidal-test materials, and negative readings in known cases of lymphopathia venerea. It was apparently very specific in the limited number of cases tested. It also is a very valuable help in diagnosing large extragenital chancroidal lesions in which the organism cannot be demonstrated.

DR. HAROLD N. COLE, Cleveland. In a way we should make an excuse for a report on a study of this sort using material such as sterilized pus when there is a vaccine on the market, but it is impossible, because of our laws, to get it in this country. It may be that some can grow the Ducrey bacillus with ease, unfortunately, that is not our experience in Cleveland. It is a most difficult procedure. We have been trying it for quite a few years. Of course, with the dmelcos vaccine one has a standardized test as against a more or less crude test in which the pus is used. Nevertheless, one gets excellent results using this sterilized chancroidal pus as a test and as a therapeutic procedure. In several cases of resistant chancroidal infection the therapeutic results from the use of this material injected subcutaneously were striking. Moreover there is a place for a test of this sort, because one encounters certain

cases in which it is exceedingly difficult to differentiate between chancroidal infection and inguinal lymphogranuloma infection. They do not always run true to form and, too, one may even get a case in which there is a double infection and, naturally, if under this condition it can be proved with specific measures instituted, the patient will respond much more rapidly. Therefore I feel that, until there is a dmelcos vaccine in this country, there is a place for the employment of a chancroidal pus vaccine of this type. What this material consists of it is difficult to say. It undoubtedly consists of a certain number of killed, macerated organisms in the pus and it probably also contains a certain amount of antibodies that have been produced by the body against this infection.

ETHER-OIL RECTAL ANALGESIA IN OBSTETRICS

MODIFIED TECHNIC

JAMES T GWATHMEY, MD

NEW YORK
AND

C O McCORMICK, MD

INDIANAPOLIS

The experimental work on which the clinical use of ether-oil rectal anesthesia is based was conducted in 1913 in the Pharmacological Laboratory of what was then the New York University and Bellevue Hospital Medical College, by Prof. George B. Wallace,¹ and in the Chemical Laboratory of the College of the City of New York, by the late Prof. Charles Baskerville.²

Twenty-four experiments on dogs were made by Wallace to determine its practicability. Typical tracings of heart and lungs of a dog under ether-oil anesthesia showed the respiration and carotid blood pressure to be evenly and fully sustained. Baskerville proved by experiments that the rate of evaporation of ether from all oils kept at body temperature in a water bath was constant, despite the changing ratio of ether.

The clinical application of these observations was reported in 1913 at the seventeenth International Medical Congress, in London.³ Clinical experience proves that ether evaporates in the human body when given with oil by rectum at the rate of about 1¼ drachms (4.5 cc) every five minutes and that it is impossible for it to leave the oil in any other ratio. In clinical experiments made in 1913 it was noted that 2½ ounces (75 cc) of ether by rectum never produced sleep in the average adult but that analgesia quite often resulted.

The application of these experimental and clinical observations in obstetric practice was made ten years later, in 1923, at the Lying-In Hospital in New York, under the supervision of Dr. Asa B. Davis, chief of staff of the hospital.⁴ At that time more than 300 confinements occurred in this hospital each month.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.

Obstetrical Analgesia. A Further Study Based on More Than Twenty Thousand Cases. *Surg. Gynec. & Obst.* 61: 190-195 (Aug.) 1930.

The agreement between Davis and Gwathmey governing the principles to be observed in developing the method was (1) to employ only drugs in common use, (2) to devise a method requiring neither specialized technic nor unusually equipped or trained personnel, and so simple that it could be used in the home or the hospital by any physician, (3) to modify or stop the administration if either the mother or the child appeared to be in danger at any time, (4) to publish the results, whether favorable or not.

After many drugs and various combinations were used^{5a} a standard formula and technic were evolved. The technic, as developed at the Lying-In Hospital, has been used in more than 15,000 cases in that hospital alone, and the method is now used in all civilized countries. A comparison of the records of three different house surgeons at the Lying-In Hospital for the month of March of three successive years (1927-1929) shows that the method has been standardized. Ninety per cent of all cases were successful with this method. Davis said before the New York Obstetrical Society in 1924, after observing the method in many cases, that he had yet to know of a case wherein either mother or child was in any way injured by this method.^{4b} In 1925 Davis^{4a} stated that the "ether practically never stops the contractions of the uterus when given at the time directed." In the second stage, the patient bears down in the usual way. Even if the drugs should prolong or stop labor, no harm is done and at any rate the patient does not suffer.

The work of Meltzer⁵ and Hooper⁶ in the laboratory, and clinical experience⁷ have proved the synergistic action of magnesium sulfate, with both ether and morphine.⁸ However, in obstetrics unpleasant results sometimes follow the hypodermic injection of magnesium sulfate. This is sufficient reason for omitting the magnesium sulfate and substituting a drug that is effective in expert hands and harmless in the inexperienced. Tuberculosis, heart and kidney diseases, and threatened eclampsia do not contraindicate the administration of ether by rectum. By substituting pentobarbital sodium by mouth for magnesium sulfate by hypodermic injection, the possibility of an occasional abscess is avoided. The technic as presented here is simplified, and made safer.

DRUGS USED IN MODIFIED TECHNIC

*Pentobarbital Sodium*⁹—Bernard Fantus¹⁰ states that "the fatal dose of the barbiturates is from fifteen to thirty times the therapeutic dose." Gillespie¹¹ reviewing all the literature regarding the barbiturates since 1904, says "No clear-cut case has yet been reported where a barbiturate in therapeutic dosage has produced death in the absence of complicating factors." Recovery is reported in several instances after more than 15 Gm (225 grains of barbital) and after 5 Gm (75 grains of phenobarbital). Recovery is reported¹² of a patient having taken 11 Gm (172 grains) of sodium

tracted hypnosis than any other barbiturate tried by us.¹² The accompanying table illustrates the relatively low toxicity of pentobarbital sodium.⁹

Paraldehyde—Sollmann¹⁴ states: "The sleep is normal and, with ordinary doses, without after-effects. Its acute toxicity is low, so that 100 Gm produced only very prolonged sleep." Bastedo¹⁵ says: "Ordinarily paraldehyde is a very safe hypnotic, its tendency being to stimulate the heart and respiratory tract." By mistake, a nurse added 2 ounces (60 cc) of paraldehyde instead of 2 drachms (8 cc) to the usual oil-ether-surgical mixture which prolonged the sleep, but the recovery was uneventful, without treatment of any kind. Another nurse added 4 ounces (120 cc) instead of

Relative Toxicity of Drugs

| | Minimum Effective Dose | Minimum Fatal Dose | Ratio |
|----------------------|------------------------|--------------------|-------|
| Pentobarbital sodium | 40 | 110 | 2.7 |
| Barbital | 225 | 310 | 1.37 |
| Amital | 72 | 180 | 2.5 |

4 drachms (15 cc) of paraldehyde to the usual ether-oil surgical mixture. The patient to whom this was administered slept from Saturday morning until Monday morning. Artificial respiration, transfusion, and the like resulted in an uneventful recovery. Two drachms is the amount used in the present obstetric mixture. This amount has been given thousands of times with the ether-oil mixture in surgery, with only favorable results. Paraldehyde adds nothing to the analgesia but makes the whole technic smoother and safer.

Ether—Ether is the most nearly universal anesthetic. The nausea and vomiting that usually follow inhalation anesthesia without preliminary medication are practically eliminated by giving the ether by rectum and using a barbiturate as a preliminary. In suitable dosage and with proper technic, ether rectally may be a sedative, an analgesic, or an anesthetic. Equal parts of ether and olive oil of each 2 drachms (8 cc) placed in the rectum will act as a sedative in whooping cough and effectively prevent a coughing spasm in young children. In larger dosage up to 2½ ounces (75 cc) with half the amount of oil, by rectum, it acts as an analgesic only. With increased volume, but in the same proportion (4 to 6 ounces [120 to 180 cc] of ether), it acts by rectum as a powerful anesthetic. It is promptly excreted by the lungs of both the mother and the new-born infant. Tuberculosis is no contraindication to ether given by rectum. As it boils at 96° F., it passes in and out of the fetus without any cumulative effect.

Ether given by rectum affects the sensory nerves to a far greater extent than when given by inhalation. Frequently patients under ether-oil analgesia may be conversed with while being operated on. The fact that the upper portion of the brain is but little affected is most important in obstetrics. The patient, even when seemingly unconscious, will "bear down" when told to do so. The 2½ ounces of ether by rectum will never produce surgical anesthesia. It is therefore unnecessary for the obstetrician to be present when this is given. This amount may be considered standard for the average adult (130 to 170 pounds [59 to 77 Kg]), but may be increased to 3 or decreased to 2 ounces for those overweight or underweight. The experienced obstetrician will individualize, with both the ether and the pentobarbital sodium.

Quinine—Quinine¹⁶ stimulates and continues the contractions of the uterus when labor pains start. In the dosage used, it is ineffective in initiating or producing premature labor. It will intensify weak labor.

Fig 2—Apparatus for McCormick rectal analgesia.

pains. It is more persistent than solution of posterior pituitary and safer, since it never produces uterine spasm. In the isolated virgin guinea-pig uterus, Lieb¹⁷ found that a 1:100,000 solution brought an immediate increase in the rate and strength of the contractions. At the Lying-In Hospital, when quinine was omitted from

the solution labor was delayed and uncertain in several hundreds of cases, with its reintroduction, labor was progressive and uneventful. Qualitative tests for quinine excreted in the urine in 100 cases gave ninety-two positive and eight negative results. An erythema develops once in about 500 cases and may be disregarded. The fatal dose is 8 Gm (128 grains), but

Fig 3—A aseptic syringe equipped with a 22 French catheter B 5 ounce funnel equipped for gravity instillation

recovery has followed a dose of 30 Gm (480 grains). The amount used at one time with this method is 1.25 Gm (20 grains). Clinical experience proves that it is practically harmless in the dosage used, but if omitted labor is delayed.

TECHNIC WITH NEW MODIFICATIONS

Changes in the obstetric technic have been made by McCormick¹⁹ and his associates in the obstetric department of Indiana University School of Medicine. Briefly, these modifications involve the following:

1 The omission of magnesium sulfate by hypodermic injection, and the substitution of pentobarbital sodium (nembutal) by mouth. For the nurse, this is easier to give, for the patient, it is safer and easier to take.

2 The substitution of the degree of the patient's suffering for the amount of cervical dilatation as a time criterion for the administration of the sedatives and the rectal instillations. Experience has demonstrated that the distress of the patient is a more practical guide than cervical dilatation.

3 The explanation, to the patient, of the steps to be taken for her convenience and safety.

4 The instillation of the rectal mixture with the McCormick apparatus (fig 2), which is completed readily within thirty seconds, falling within any pain interval, instead of with the funnel method, requiring from ten to fifteen minutes. No assistant is required, and the instillation is higher and better retained.¹⁸

5 The substitution of a 5 to 10 per cent (a heaping tablespoonful in 1 quart of water) solution of sodium bicarbonate enema for the usual soapsuds enema. If the pentobarbital sodium is not given within eight hours after the initial enema, the enema is repeated. It should not be given just before the rectal instillation. If this is unavoidable, any remaining water is siphoned back before the rectal instillation.

As with all other forms of analgesia and anesthesia, experience gives added success.

18 The McCormick apparatus is not essential. With an assistant the funnel method or an aseptic syringe equipped with a catheter has proved quite practical (fig 3).

ETHER-OIL MIXTURE

The formula for the rectal mixture, as now used, is ether, 2½ ounces (75 cc), quinine alkaloid 20 grains (1.3 Gm), alcohol 45 minims (3 cc), paraldehyde 2 drachms (8 cc) and liquid petrolatum or olive oil enough to make 4 ounces (120 cc).

These agents are mixed in the following order: (1) quinine and alcohol, (2) paraldehyde, (3) ether, (4) oil. The mixture is then stirred, strained through cotton, bottled and corked.

PRELIMINARY PROCEDURE

The patient, having had a cleansing enema and a bath, and having been placed in bed, is addressed by the obstetrician as follows: "We are desirous of making your labor as painless as possible. Therefore, when your pains become uncomfortably severe, let the nurse know and she will give you a couple of capsules¹⁹ to relieve you. When the pains again become uncomfortable notify her as before and she will give you another capsule¹⁹ and perhaps a hypodermic²⁰. Later when this medicine begins to lose its effect, she will inject a solution into your rectum."²¹

The following routine is then employed. Instead of the first two intramuscular injections of magnesium sulfate the patient is given orally 3 grains and 1½ grains (0.2 and 0.1 Gm) respectively of pentobarbital sodium. One-sixth or one-fourth grain of morphine is usually given hypodermically with the second instead of with the first dose of pentobarbital if the patient is a primipara and labor is active. On the other hand, if the labor is not uncomfortably active, or if it is of the prolonged type, the second dose of pentobarbital may be repeated once or oftener before the morphine is given (not more than 10 to 12 grains [0.6 to 0.7 Gm] in twenty-four hours). When the effects of the morphine begin to wear off, the ether-oil-quinine solution is administered by rectum and repeated as often as required, except that the quinine is omitted after the second instillation. Usually one instillation suffices. Morphine is omitted if delivery is anticipated within four hours and is rarely

Fig 4—Analgesia tray and patient in position for instillation.

necessary if the patient is a multipara. If delivery is anticipated within four hours, the oral administration of pentobarbital and the rectal ether-oil instillation are promptly given, simultaneously. After the pentobarbital is given, the patient should be kept quiet. She is

19 Pentobarbital sodium 1½ grains (0.1 Gm) repeated if necessary.
20 Generally speaking, if the patient is a primipara and delivery is not expected within twenty-four hours one-sixth or one-fourth grain (0.016 or 0.016 Gm) of morphine is given.
21 Ether-oil-quinine—McCormick.²²

given only the necessary attention. The environment should be such as to favor her falling asleep. If she is in a ward, the bed is screened, if in a room, the shades are lowered and the light is excluded, the door is closed. The patient must be watched while asleep, as she may turn from side to side during contractions and fall out of bed.

RECTAL INSTILLATION

The patient is placed on her left side, with the buttocks at the side of the bed. Seaweed or tragacanth lubricating jelly (not petrolatum) is liberally applied about the anus. A well lubricated 22 F catheter is inserted from 6 to 8 inches into the rectum. It is important that the catheter pass the presenting part. It is held in place with the left hand. With the right hand the bulb is compressed at the conclusion of a pain not more than twenty or thirty times a minute (fig 4). The mixture may be poured in a funnel (fig 2B). During the administration of ether mixture the patient is told to breathe deeply with her mouth open, and to draw up with the anal sphincter, as if she were trying to avoid expelling gas, this will induce reverse peristalsis and permit the fluid to run in more rapidly. After all the ether mixture is passed out of the catheter, the catheter is clamped to prevent air being drawn into the return. The catheter is then gently withdrawn. Pressure is made with a towel over the anus during three or four contractions after the catheter is withdrawn. The patient may now be on her back or whatever position is most comfortable. The quiet appearance of the patient should not be misleading, she may be having strong contractions and should be watched carefully. The rectal instillation may be given at intervals of two and one-half hours if necessary. At actual delivery, ethylene, nitrous oxide or ether is given by inhalation, but not chloroform. When the baby is born, if a gas-oxygen apparatus is used, all anesthetic is cut off, and 5 per cent carbon dioxide and oxygen, under pressure, is given before the cord is cut.

SUMMARY

After ten years' experience with the original and other methods and many modifications, the advantages of this modified method and the reasons for its popularity are summed up by numerous authorities and listed by one of us (McCormick) as follows:²²

- 1 It is the safest of all satisfactory analgesias used to date. Several series of many thousands of cases have been reported, no maternal or infant mortality being attributed to its use. The largest of the series is a group of 20,000 cases, reported in 1930.¹⁴
- 2 There are no major physical contraindications. It may be given with impunity to patients presenting cardiac disease, tuberculosis, pneumonia, acute bronchitis, nephritis, eclampsia, placenta praevia, and pelvic disproportion. In the event of a pathologic condition of the rectum, it is no more irritating than the soapuds enema formerly used. It is used with equal facility in the home and in the hospital.
- 3 It serves as a satisfactory analgesic in 85 to 95 per cent of cases. Most failures are due to faulty technique.
- 4 It requires but little equipment and experience and is readily administered by the general practitioner.
- 5 It can be started early in the first stage and administered any time during labor.
- 6 The patient is much more cooperative than in "twilight sleep" or sodium amytal analgesia.

7 In addition to analgesia, it affords a most gratifying amnesia, the patient rarely having more than a vague recollection of the labor.

8 The physician does not have to be in constant attendance, the average instillation being effective for from two to six hours.

9 It is not likely to prolong labor and not infrequently the second stage is shortened.

10 The baby suffers no ill effects.

11 It incurs no complications of labor or postpartum pathologic condition.

12 Forceps deliveries are decreased in number, and lacerations are no more frequent than with other methods of delivery.

13 Mental and physical shock are lessened. Normal appetite is restored within a few hours following delivery.

14 It is relatively inexpensive, especially compared with nitrous oxide and ethylene gas. At wholesale cost the ingredients of the ether-oil mixture total only a few cents.

15 It dovetails excellently with gas and inhalation ether as adjuvants during the perineal stage and instrumentation, only 50 per cent or less of the usual amount of ether being necessary. Chloroform should never be used in conjunction with the method.

17 In performing a cesarean section under local anesthesia, it affords an excellent preliminary.

18 This form of analgesia is available to practically every woman in labor.

VINYL ETHER OBSTETRIC ANESTHESIA FOR GENERAL PRACTICE

WESLEY BOURNE, M.D., F.R.C.P. (CANADA)
MONTREAL

Although the usefulness of vinyl ether in obstetrics has already been described,¹ this drug may be dealt with again on account of the continuation of its employment at the Royal Victoria Montreal Maternity Hospital, from which increased confidence has been gained concerning its relative safety. It is therefore proposed to recount some of its effects, particularly those on the liver, to add new information of its action on the organ and to point out that vinyl ether seems to be especially suitable for obstetric anesthesia in general practice.

The original report of the use of vinyl ether in obstetrics gave an account of its administration to 152 parturient women and a detailed analysis of the first fifty cases. The condition of the patients as well as the procedure of delivery varied considerably. Several of the women were "toxic" and the deliveries varied from spontaneity to high forceps and low cesarean section. The vinyl ether was administered either by dropping it on a small "open" mask or with oxygen in a closed system having a carbon dioxide absorption attachment (Foregger). The latter method is much more desirable, as it not only precludes asphyxia and waste of material but affords a means of mixing vinyl ether vapor with any of the anesthetic gases. Whenever it seemed advisable, a preliminary period of intermittent evanes-

¹ Bourne Wesley. *Lancet* 1:566 (March 17) 1934.

cent anesthesia (it is almost impossible to produce analgesia with vinyl ether) was produced for each earlier severe labor pain

Among the first fifty patients, the bromsulfalein dye test² for liver function was carried out on four, including a very "toxic" woman of the renal type. A striking comparison was afforded by these liver function tests, and those after chloroform administered under similar conditions. The data showed that after vinyl ether very little dye was retained in the blood, that is, there was practically no liver damage, while the administration of chloroform was followed by marked dye retention indicating definite liver impairment. Leake, Knoefel and Guedel³ have reported no gross pathologic changes in the liver, heart, lungs, kidneys and other tissues of dogs, Goldschmidt, Ravdin, Lucke, Muller, Johnston and Ruigh⁴ found liver necrosis in dogs only after vinyl ether had been given for three hours, and none in monkeys. Although fully appreciating the value of these observations, Raginsky and I⁵ thought it worth while to study more thoroughly the actions of vinyl ether on the liver. Accordingly, it was administered to normal dogs, to dogs with chloroform-damaged livers, and to partially starved dogs, and the liver function was measured by the previously mentioned dye test. The following is quoted from the results:

1 Vinyl ether anesthesia in normal dogs does not alter the liver function appreciably. In those cases in which cyanosis is a feature of the anesthesia, moderate liver damage occurs which is not due directly to the drug but to the associated anoxemia.

2 Vinyl ether anesthesia does not enhance the liver function damage produced previously by the inhalation of chloroform, nor does it delay the period of recovery from this damage.

3 The effect of vinyl ether anesthesia on the liver function in partially starved dogs is not appreciably different from that produced in normal animals.

The problem of the effects of anesthetics on the liver has been approached in another manner by Dr. Hans Molitor⁶ of the Laboratories for Pure Research, Merck & Co. He inserts cannulas in the bile duct and in the duodenum of rabbits, then he collects measures and weighs the bile and reinjects it into the duodenum. The bile passes a drop recorder before being collected, so that the slightest change in the bile secretion may be recorded. In a control animal the bile flow over a period of four hours shows a pronounced decrease during the first hour and a very slow and gradual increase during the following two hours. When chloroform is administered to such an animal, he records an immediate decrease in bile secretion, which continues after the anesthetic has been withdrawn. When ethyl ether is used, he finds a very slight initial decrease and a subsequent increase in the flow of bile, not unlike that of the control animal. When such an experiment is done with vinyl ether, whether the material is pure or impure, there is no change in the usual flow of bile, even though the administration lasts for two hours and the anesthesia is profound. Dr. Molitor has gone on to show the powerful effects of anoxemia in this regard. He applies a mixture of 95 per cent nitrous oxide and

5 per cent oxygen and obtains a prompt drop in the flow of bile, in fact, the secretion comes almost to a stop. At this point he changes to a mixture of 80 per cent nitrous oxide and 20 per cent oxygen, along with a sufficient amount of vinyl ether to produce very deep anesthesia, and in spite of the vinyl ether the bile starts to flow again, reaching its normal rate within five minutes.

Seemingly antithetical to these five sets of favorable observations concerning the actions of vinyl ether on the liver, there is a brief account in a footnote of one of the fore-mentioned papers⁴ of two cases presenting "evidence of central lobular necrosis of the liver." These cases were reported through the kindness of Dr. Dean Lewis of the Johns Hopkins Hospital. I have obtained permission from Professor Lewis to publish the following more extended details of these two fatalities:

Mrs. H. G. White, aged 23, admitted to the accident room at 10 p. m., July 11, 1933, complained of abdominal pain of two days' duration. The patient was obese, weighing 76 Kg, had a sallow complexion and was obviously sick. The abdomen was pendulous and full, with definite tenderness on deep pressure in the right lower quadrant. There was nothing striking in the rest of the physical examination. The throat was clear, the lungs appeared normal and the heart was of normal size with an apical blowing systolic murmur. There was no peripheral edema. The blood pressure was 110 systolic, 65 diastolic. The white blood cells numbered 19,200. The diagnosis was appendicitis.

An exploratory laparotomy with appendectomy was performed July 12, 1933, under divinyl ether anesthesia. The induction period was eight minutes. The patient was mildly hysterical and noncooperative prior to anesthesia, but induction was smooth and rapid and there was no anoxemia. Complete relaxation was easily obtained, but an amount in excess of the usual dosage of divinyl ether was required. The operation was completed in one hour and thirty-five minutes, and 275 cc. of the agent was used. The patient was fully conscious six minutes after cessation of anesthesia.

The immediate postoperative course was uneventful, with the exception of slight nausea and vomiting on the second day. On the fourth and fifth days the patient complained of heart burn pain in the chest and headache. The physical examination was negative with the abdomen soft. Early on the sixth day the pulse rose to 160 with respirations to 35 or 40 and the patient became unresponsive, the arms were spastic and the pupils dilated but reacted to light. The white blood cells numbered 30,000. The respirations gradually slowed and the patient died in midafternoon in apparent respiratory failure. The impression was cerebral vascular accident, involving the basal nuclei or multiple fat emboli. The autopsy showed a slight fat embolism with midzonal necrosis of the liver, an acute splenic tumor, chronic cystitis which was slight, a small ulceration of the vaginal mucosa, a wide foramen ovale, and hematoma and necrosis of the subcutaneous tissue around the operative wound.

J. H. R., a white man, aged 54, admitted to the hospital July 18, 1933, complained of epigastric discomfort after meals and loss of from 15 to 20 pounds (6.8 to 9 kg). Physical examination was negative except for the loss of weight, the ventral hernia and bilateral inguinal hernia, and very slight tenderness on deep pressure in the epigastrium. The liver was not enlarged. The blood pressure was 165 systolic, 90 diastolic. Hemoglobin was 42 per cent. The white blood cells numbered 8,400. The urine showed albumin one plus. Transfusion of 500 cc. of citrated blood increased the hemoglobin to 62 per cent. The operation was performed July 25. A resection of the stomach with gastro-enterostomy was done under divinyl ether anesthesia, 350 cc. The duration of the operation was two hours and forty minutes. The operation revealed a large carcinoma of the stomach posteriorly with several suspicious pinpoint white spots in the liver. The patient left the table in good condition and was fully conscious ten minutes after completion of the operation. The induction was rapid

⁶ Molitor, Hans. Personal communication to the author.

and smooth, with no cyanosis. Maintenance anesthesia was light throughout, and the patient was satisfactorily relaxed for the surgeon. The physical condition was excellent the evening of the operation with the temperature 100 F, pulse 98 and respiratory rate 20. There was no nausea or vomiting. On the second postoperative day the temperature was 101, pulse from 110 to 130, and respiratory rate 24. The patient was drowsy but quite comfortable. He voided 125 cc of bloody urine. On the fourth postoperative day at 2:30 a.m. the patient died suddenly in apparently normal sleep with no previous changes in temperature, pulse or respiratory rate. The impression was sudden massive hemorrhage. The autopsy report was localized peritonitis, central and midzonal necrosis of the liver, pulmonary edema, adenoma of the prostate, pyelitis cystica, extreme mononuclear infiltration of papillae and pyramids of the kidney, solitary calcified tuberculous nodule in the left upper lobe.

In each case the divinyl ether was administered by the open drop method, a chloroform mask with eight thicknesses of gauze being used. No oxygen was used and there was no anemia at any time in either case.

Although it is true that the first case showed midzonal necrosis, it is pointed out that when liver necrosis does follow anesthesia it usually occurs at the center of the lobule, and whereas in the second case there was central as well as midzonal necrosis of the liver, this man was very wasted, very anemic, had a large carcinoma of the stomach with suspicion of metastases in the liver, and was subjected to an operation that lasted two hours and forty minutes. In fairness it must be conceded that his was a hazardous outlook and that the liver necrosis may not be attributed too seriously to the vinyl ether.

Since the previously mentioned 152 vinyl ether anesthetics there have been 500 more in this clinic, making a total of 652 administrations of vinyl ether to parturient women of all kinds and conditions. Among all these there was only one case which was followed by untoward results.

A primipara, aged 23, due March 19 1935, was admitted to the hospital February 27 in indifferent labor. Pregnancy had been apparently normal throughout. Labor progressed normally and the patient was delivered spontaneously of a living child. Vinyl ether was given for forty minutes. Some thirty hours later a jaundice developed, which increased daily. Analyses of the blood showed rapidly increasing urea, uric acid, nonprotein nitrogen and the van den Bergh reaction indirect. Urinary output dropped to practically zero, the patient became first restless and then comatose, the jaundice deepened, blood transfusions and injections of salines and dextrose intravenously seemed to do no more than prolong life. After five days of illness she died. The last figures of chemical analyses of the blood were urea 175, urea nitrogen 140, uric acid 21.4, creatinine 11.0, amino acids 181. The van den Bergh indirect reaction was 30 units. Postmortem examination was refused, but a small piece of liver was obtained through an abdominal incision. Prof. T. R. Waugh of the Pathological Institute of McGill University gave the following report: The specimen consisted of two pieces of liver the size of lima beans, yellowish green with red punctate markings. Section showed a hemorrhagic necrosis of the parenchyma, which started about the periportal spaces and invaded a zone of the lobule, varying from 3 to 6 cells deep in this area. The remaining parenchyma showed some fatty metamorphosis. The picture agreed with that encountered in eclampsia.

The anatomic summary was periportal hemorrhagic necrosis (eclampsia).

Having now obtained more exact knowledge of the pathologic changes concerning the two deaths at the Johns Hopkins Hospital just mentioned, and with Professor Waugh's report before me, I feel justified in the belief that vinyl ether was not the cause of the liver damage in any of these three cases. Although I

do admit that it probably did enhance liver impairment in the first two anesthetics, which were unusually long, it is very likely that the results would have been the same had ethyl ether been the anesthetic. This opinion is expressed because it has already been clearly shown from repeated experiments that vinyl ether does not effect any more impairment of hepatic function than does ethyl ether. In these experiments there were no complicating factors and the conditions were under absolute control. Who can say with any sense of assurance that the livers in these three clinical cases were not diseased before the administration of vinyl ether?

Another argument in favor of vinyl ether has recently come from the Pharmacological Laboratory of the University of California Medical School. Peoples and Phatak⁷ made a comparative study of the effects of ethyl ether, ethylene and vinyl ether on rabbit intestine. They found that whereas ethyl ether always caused an immediate and marked loss of tone and inhibition of movement of the intestinal muscle and ethylene caused a slight and transitory loss of tone with an occasional increase in the amplitude of contraction, vinyl ether uniformly increased the tonicity of the intestine. They conclude that their observations on the action of vinyl ether on isolated intestinal muscle indicate that in this respect, as in other phases of its pharmacologic action, it has properties resembling ethylene more than ethyl ether. Indeed, since it definitely increases intestinal muscle tonus, it may be expected to be followed by even less postoperative stasis when used clinically than ethylene, which is reputedly so much better in this desideratum than ethyl ether. This would seem to be a point in favor of the use of vinyl ether in operative obstetrics, especially cesarean section, as against ethyl ether.

In verification of this work of Peoples and Phatak, Molitor⁸ has shown me a tracing of intestinal action recorded by the method of Straub,⁹ which shows that vinyl ether does not interfere with the automatic movements of the intestine, whereas ethyl ether will stop these movements. Molitor has done similar experiments on the uterus, he finds that, like ethyl ether, vinyl ether does not affect uterine contractions, which supports the impressions received in this clinic.

Since the more extended employment of vinyl ether in this clinic, with the exception of the case of eclampsia already described, there has been no question of untoward effects, its entire suitability for use in obstetrics has become very convincing, and although those patients who have had it by the "open" method have done well enough, there can be no doubt that it is better to administer vinyl ether with oxygen, if for no other reason than that every anesthetist knows something of the benefits of adding oxygen to anesthetic vapors. Ravdin⁹ states that "there is no doubt that the increase of necrosis in the experimental animal is markedly reduced when a plentiful supply of oxygen is at hand." The extreme volatility of vinyl ether is such that it is very wasteful to give it by the "open" method. It is therefore preferable to employ a closed-system apparatus, fitted for supplying oxygen and for absorbing carbon dioxide, so that a very small quantity of anesthetic will suffice for the longest case, in other words, the longer the anesthesia the smaller will be the

⁹ Ravdin, I. S. Personal communication to the author.

quantity used per unit of time. Such an apparatus should be cheap and should in a short time more than pay for itself by precluding waste of material.

SUMMARY

1 When vinyl ether is used to produce anesthesia sufficient for obstetric procedures, it apparently does not cause liver damage nor does it interfere with muscular activity in the intestine and in the uterus.

2 Vinyl ether seems to be particularly suitable for obstetric anesthesia in general practice on account of its safety for mother and child, its ease of administration, the rapidity of its action, the satisfactory maintenance of any desired degree of narcosis, and the early uneventful recovery.

3 Although vinyl ether may be given with relative safety by the "open drop" method, it is preferable to administer it in a "closed" manner with oxygen.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs GWATHMEY AND MCCORMICK
AND DR BOURNE

DR R A GAUHAN, Hazelton, Pa. I will confine my discussion to the rectal ether anesthesia as worked out by Dr Gwathmey. For the past twelve years in our hospital we have been using the rectal oil anesthesia in obstetrics. We transferred it to the surgical department, so that in conjunction with Dr Gwathmey we worked out a technic of rectal anesthesia plus the use of morphine and magnesium sulfate which has been very successful. We use this type of anesthesia in all our thyroid work. Our technic is as follows: Preceding the operation the patient is given two soapsuds enemas, one at 9 o'clock the night before, the other at 5 a. m. One hour before the operation the patient is given three ampules each 2 cc. representing morphine sulfate one-eighth grain (0.008 Gm.) and solution of magnesium sulfate 50 per cent, intramuscularly at fifteen-minute intervals. Following the injection of the last dose, 1½ ounces (45 cc.) of ether with 2 ounces (60 cc.) of olive oil, thoroughly mixed, is slowly injected into the bowel and retained. If the patient is very light in weight we use 1 ounce (30 cc.), for those a little heavier we use an ounce and a half. We seldom go any higher than an ounce of ether by bowel. The patient is then moved to the operating room. At the beginning of the operation approximately 3 cc. of a 1 per cent solution of procaine hydrochloride is injected into the skin. Immediately after operation a colonic irrigation of tepid water is given until the return is clear. Following this 10 ounces (300 cc.) of dextrose solvent 5 per cent with 1 drachm of aqueous solution of iodine (Lugol's solution) is given by bowel every six hours for four doses. Fowler's position, physiologic solution of sodium chloride by hypodermoclysis, digitalin and morphine sulfate are given as a routine. Liquids are given by mouth as desired. We have not had one death from this anesthesia in 1,500 operative cases in the past ten years in the City Hospital. There is no effect on the respiratory center or the heart. The blood pressure remains constant. The patient comes to the operating room calm, a big help in toxic goiter cases. There is perfect anociassociation. The patient is able to talk during the operation and never loses consciousness. This is a big factor in operating on thyroids as the danger of injuring recurrent laryngeal nerves is markedly lessened. There is less hemorrhage in this type of anesthesia. Breathing is regular, and there is no collection of mucus in the throat or coughing. The patient is longer without pain. When seen in the ward in the evening the patients will say that they haven't any pain. There is much less nausea and vomiting. I am indeed indebted to Dr Gwathmey for his help in developing our technic of synergistic analgesia.

DR LYLE G MCNEILE, Los Angeles. While for a normal delivery or a cesarean section the agent need only be capable of maintaining its effect in the upper level of third stage anesthesia, for a breech extraction anesthesia must be pushed to the second level, while version and vaginal hysterotomy require that the patient be brought down to the third level of third stage anesthesia. Again in obstetrics there exist as constant factors a

rise in the basal metabolic rate during labor, pain and emotional excitement, each of these directly influencing the physiologic effects of nearly all the anesthetic agents. Finally, in obstetric anesthesia one must consider not only the effect of the particular anesthetic agent used on the individual to whom it is given but also the immediate and remote effects on the child. In my opinion these varying demands, the physiologic factors influencing the action of the various anesthetic agents used in obstetrics and the limitations of these same agents are responsible for the wide variations of opinion regarding the choice of anesthesia. My associates and I have used rectal ether and oil, or some modification, since its introduction by Gwathmey and Davis. It is used in both the outdoor and indoor services. First given according to the original technic described, we soon discontinued the use of magnesium sulfate as having no noticeable effect. Later we substituted dial-Ciba for the morphine, with increasingly satisfactory results. More recently we have been using pentobarbital sodium and scopolamine instead of the original morphine and magnesium sulfate. Amnesia has been greatly increased. I regard the method after many years of trial under varying and often adverse conditions as entirely safe and one to be highly recommended for general use.

DR JOSEPH B DE LEE, Chicago. It seems to me that it is much more sensible to anesthetize that portion of the patient on which one is going to operate than to desensitize the whole patient. The two elements in successful anesthesia are the mind and the body. In topical anesthesia the anesthetizer and the anesthetic are one, and this one should compose both the mind and the body of the patient. Mind treatment is essential in all anesthesia. I might say that Dr McNeile would get better results with his local cesarean sections if he used mind treatment, in fact, that is a large part. If completely painless labor is the goal, every woman must be delivered under ether or gas by cesarean section or possibly by local anesthesia after her mind is treated. If the woman is to be delivered from below the labor must have been present long enough to be thoroughly established, so that the anesthetics will not stop the process of delivery. Is there any anesthetic that will allow all pain to be safely abolished from this point? No there is not. The barbiturates, morphine, dilaudid, chloroform, scopolamine, cyclopropane, tribrom-ethanol, all increase the mortality and morbidity of labor for mother and baby. They prolong the first stage, they increase the necessity for operative intervention, and the deep anesthetics under which nearly all babies are delivered nowadays cause asphyxia, postpartum hemorrhage and bronchitis, which may lead to local infections or pneumonia or to something worse. But I hasten to add that analgesics and anesthetics given properly actually reduce the dangers of labor. First, they help the mind, and labor is not such a deep psychic insult on impressionable persons, secondly, they prevent premature and harmful intervention by the doctor. He is therefore not affected by the cries of the woman and the importunities of her relatives. He allows the labor to take a more natural course. A high head comes down into the pelvis, the cervix is permitted to dilate fully, and the doctor is not precipitated into action. I believe that physicians should not aim at a completely painless delivery but should administer analgesics and anesthetics freely in the first stage, and, in the second stage, effect a delivery under ethylene gas or preferably local anesthesia. Throughout, and beginning during pregnancy, the mind should be brought into a psychologically normal condition.

DR CARROL J FAIRO, Cincinnati. I should like to ask just two questions of Drs Gwathmey and McCormick. What has been their experience with proctitis after rectal ether instillation? Secondly, I notice that otologists are now very suspicious of large doses of quinine having some effect on the hearing apparatus of the new-born child. I should like to ask what their reaction is to this complaint of the otologists.

DR H F BECKMAN, Indianapolis. I think that the picture portrays the results obtained by rectal ether analgesia better than words can relate. Its safety is a great factor. The dose of ether used, 2½ ounces (75 cc.), I do not think any one would challenge as a toxic dose, and it will not be repeated until again demanded or required. I believe that using the patient as the index for the degree of suffering is certainly appropriate and practical. No one in this presentation has considered the child. There is no specified time to direct the physician or to explain

what is depressed breathing or delayed breathing in the newborn child. There is a certain amount of depression in all births for the child. This manifests itself either as asphyxia or as shock. I have recently had reviewed about 870 cases for this principle. The criterion of asphyxia and depressed respiration was not clearly analyzed, but out of this number it was decided that morphine and scopolamine were the greater depressants manifesting themselves on the child in about 30 per cent of the cases. I think that Shute and Drury of the Chicago Lying-in Hospital showed that the greatest effect of morphine manifests itself on the child during the third hour. Hence in administering these drugs it is wise to observe this time limit. With ether, however, this depressing effect was not observed. This was present in only perhaps 8 per cent of the cases. Hence I like the result obtained by this method and feel that it can be recommended as regards its safety for both mother and child.

DR MABEL H. OTIS, Moline, Ill. The biggest problem in obstetrics was defined by Dr DeLee when he said it is the mental treatment. It is the fear with which this supreme effort is approached. If that could be relieved, the anesthetic would not be a matter of utmost importance.

DR. WESLEY BOURNE, MONTREAL. Vinyl ether would seem to be more useful to general practitioners than to those obstetricians who have the facilities for indulging in the better anesthesia which a large clinic should afford. Vinyl ether would seem to offer an opportunity for replacing the much more dangerous chloroform. It is equally rapid in its action, or rather more so, one or two inhalations of vinyl ether vapor are sufficient to relieve the pains of labor. Almost any one can give vinyl ether with much greater safety than when chloroform is given even with special care. Chloroform should be banished and relegated to a historical position.

DR. C. O. McCORMICK, Indianapolis. I recommend the use of rectal ether as a basic analgesic before cesarean section, especially if the section is done under local anesthesia. If inhalation anesthesia is employed, whether ether or one of the gas anesthetics, approximately only half the usual amount is necessary. Because of the narrow margin of safety, chloroform should never be used in conjunction with rectal ether. While formerly there was an occasional rectal irritation following rectal ether, since substituting a 5 to 10 per cent (1 heaping tablespoonful to 1 quart of water) sodium bicarbonate enema for the soapsuds enema, its occurrence has been greatly minimized. As to the auditory effect of the quinine on the infant, I cannot cite figures to bear one way or the other. I know of one authority who reports 1,000 cases in which he uses 30 grains (2 Gm.) of quinine per instillation, repeating as indicated. That the risk is quite light is evidenced by absence of increased deafness in the South, although countless malaria-infected expectant mothers partake freely of large quantities of quinine. No case of auditory injury in the child has come to our attention. By carrying the patient far into active labor under the influence of pentobarbital sodium, quinine can be wholly omitted without disadvantage.

DR. JAMES T. GWATHMEY, New York. Ether by inhalation is absolutely contraindicated for tuberculous patients. I have given ether by rectum, 2½ ounces (75 cc.) three times a week for six months to a tuberculous patient with the idea that ether given in that way might affect the tubercle bacillus. It had no effect, either good or bad, so I discarded it although the patient seemed to think it did her lots of good. Her chart showed no change whatever. I have given it by rectum to patients with heart disease with no bad effects. Lundy of the Mayo Clinic has stated that, if the patient has one good kidney, he doesn't hesitate to give ether by rectum. Two and one half ounces of ether by rectum cannot be considered an anesthetic, it is an analgesic. The patient is never carried to the stage that an anesthetist is required. Even in a patient weighing 100 pounds (45 Kg.) it is an analgesic pure and simple. For that reason I think that it is perfectly safe.

Syphilis—Aortic aneurysm is the most frequent mediastinal tumor and may have no signs whatever. It is the part of wisdom to consider every patient known to have syphilis as a potential case of cardiovascular syphilis.—W. D. Reid quoted by Fisher, Alexander. *Aphorisms in Clinical Medicine* *Canad J Med & Surg* 77 166 (June) 1935.

THE USE OF BENZEDRINE FOR THE TREATMENT OF NARCOLEPSY

MYRON PRINZMETAL, M.D.

LOS ANGELES

AND

WILFRED BLOOMBERG, M.D.

BOSTON

Benzedrine (β -phenylisopropylamine) is a sympathomimetic compound closely related to ephedrine and epinephrine (fig. 1). Pharmacologic studies indicated that this compound has a more stimulating effect on the higher centers of the central nervous system than ephedrine, as manifested by its ability to awaken experimental animals from intraperitoneal barbituric anesthesia and by its insomnia-producing effect in human beings.¹ For this reason it was thought that it would be of interest to try this compound in clinical conditions in which this type of action would be desirable. Moreover, the compound seemed particularly suited for such application because of its low toxicity, its small cost and its prolonged action, as well as because of the fact that its side effects, such as stimulation of the peripheral sympathetic system, are not marked.²

Narcolepsy was chosen as the condition to be studied because the stimulation of the central nervous system induced by ephedrine has been found to be of therapeutic value in this disease.³ The effect of benzedrine in other neurologic conditions, especially certain forms of asthenia, is now being studied.⁴

Nine patients with typical histories of narcolepsy were selected for study. In all instances the disease was well established and the patients fell asleep at least three times a day. In seven instances cataplexy and other conditions associated with narcolepsy were present. Seven of the patients had been taking ephedrine in the usual therapeutic doses for a considerable period of time, but only one obtained complete relief from the symptoms. Five noticed some improvement, and one, no improvement.

Of the nine patients treated, four were hospitalized for more accurate control. Throughout the period of the experiment on these patients they were kept in ignorance of the medicine they were receiving and of the changes in the dosage, in order to rule out any psychic effect. Since both benzedrine and ephedrine, in aqueous solution, have a salty taste the patients were given physiologic solution of sodium chloride by mouth at the regular medication time when they were not taking either of the effective drugs. Careful record was kept, with the assistance and cooperation of the

Dr. Prinzmetal is National Research Council Fellow in Medicine. Benzedrine is the name in New and Nonofficial Remedies for an ephedrine like compound described as racemic desoxy nor-ephedrine or as racemic benzylmethyl carbinamine. It has been supplied under the names phenylisopropylamine and β -phenylisopropylamine.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard) Boston City Hospital and the Department of Medicine Harvard Medical School and the Neurological Service Boston City Hospital the Department of Neurology, Harvard Medical School Boston, and the Department of Internal Medicine Washington University School of Medicine St. Louis.

patient, of the number and duration of sleep attacks each day, as well as of attacks of cataplexy. At the start of each experiment, to establish a level and for a control, the patient was given physiologic solution of sodium chloride for a period of from three to seven days. Then for several days, varying doses of benzedrine (phenylisopropylamine hydrochloride)⁵ were administered, followed by equivalent doses of

Fig 1—Comparison of chemical structure of benzedrine ephedrine and epinephrine

ephedrine sulfate⁶ for several days. Then, for a final period, benzedrine was again given.

The dosage of benzedrine varied from 10 mg once daily to 40 mg three times a day, depending on the age of the patient and the severity of the disease. The five ambulatory patients could not be so carefully controlled, but with them also benzedrine and ephedrine were alternated, without their knowledge of the change.

RESULTS

In all instances complete relief from the attacks of sleep, and practically complete relief from cataplexy, resulted when suitable doses of benzedrine were given (as shown in the table and in figure 2). On an average, this compound was approximately three times as effective as ephedrine. In four instances huge single doses of ephedrine, as high as from 80 to 150 mg, failed to give relief, while moderate doses of benzedrine, such as 30 mg, afforded complete relief from symptoms. In only one instance (case 8) did ephedrine prove as effective as benzedrine, in no instance did it prove more effective. No diminution in the effectiveness of benzedrine has been observed as a result of its use over comparatively long periods of time. Patient 2 has been taking this compound for fourteen months and still obtains complete relief from symptoms.⁷

UNTOWARD SYMPTOMS

In several instances the patients complained that, although they did not fall asleep during the day, they also could not sleep at night. This was remedied by giving a smaller or no evening dose. Patients 7 and 9 complained of hyperexcitability and marked restlessness and showed evidence of overstimulation of the central nervous system, as manifested by dilated pupils and inability to relax. Reduction of the dosage resulted in disappearance of these troublesome symptoms but still gave complete relief from the narcolepsy.

There appears to be some individual variation in response to benzedrine. In order to avoid untoward symptoms, therefore, it is best to start with small doses of 10 mg and gradually increase the amount until the optimal effect is obtained.

5 The benzedrine was kindly furnished by Dr Gordon Alles of Los Angeles and the Smith Kline and French Laboratories of Philadelphia, to whom we are indebted for their cooperation.

6 Ephedrine sulfate 1.25 mg is equivalent to benzedrine (phenyl isopropylamine hydrochloride 1 mg).

7 Dr William L. Long of Philadelphia has kindly informed us of a patient of his with narcolepsy who has received benzedrine with relief of symptoms. We have ourselves had four additional cases, not so carefully controlled or long enough followed to warrant inclusion in this study in which complete relief from narcolepsy has been obtained by the use of benzedrine.

CONCLUSIONS

1 Benzedrine has a profound stimulating action on the higher centers of the central nervous system.

2 In nine cases of narcolepsy complete relief of attacks of sleep, and practically complete relief of cataplexy, was obtained when suitable doses of benzedrine were given.

3 Comparative studies indicate that benzedrine is approximately three times as effective as ephedrine in preventing attacks of sleep in narcolepsy, and that in some cases it gives complete relief from symptoms that are not relieved by huge doses of ephedrine.

REPORT OF CASES

CASE 1—J S, a 26 year old Negro male student, had sleep attacks for one year. These occurred whenever he was quiet. There had been at least three sleep attacks daily. He had noticed occasional momentary spells of 'drawing up' of his leg muscles and had had occasional headaches. In 1918 he had influenza and probably encephalitis. In the past two years he had grown extremely rapidly. Physical examination showed obesity with female fat distribution. Otherwise the examination was essentially negative. The basal metabolic rate was -19 per cent and -22 per cent. The diagnosis was narcolepsy with cataplexy, ? postencephalitic. Previous treatment with thyroid extract had given only slight relief. Ephedrine, 25 mg three times a day, had given complete relief.

Experimentally, he was given benzedrine 10 mg three times daily, with complete relief. He stayed awake without any attacks of drowsiness or sleep, except on a few rare occasions when he neglected to take his medicine. Once, without his knowledge he was given a placebo instead of the benzedrine, and all his symptoms returned.

CASE 2—W L, a 21 year old white male student, had frequent sleep attacks for the past six years, so that his school work and athletic activities suffered. He had gained 30 pounds (136 Kg) in a relatively short time and had an insatiable appetite. He was well developed and slightly obese and had a stupid expression, which faded when he was stimulated by interest. The skin and hair were delicate, and there was absence of body hair. The neurologic examination was essentially negative. A roentgenogram of the skull, centered over the sella turcica, was negative. The basal metabolic rate was -23 per cent. The sugar tolerance curve was normal. The diagnosis was narcolepsy. Previous treatment with 250 mg

Fig 2—Comparative effect on number of narcoleptic attacks of benzedrine and ephedrine in case 9. Upper block shows number of daily attacks of sleep, lower block shows medication used and dosage. Shaded columns: physiologic solution of sodium chloride; white columns: benzedrine; black columns: ephedrine.

of thyroid extract daily gave only slight relief from symptoms. Ephedrine 25 mg every six hours during the day relieved him at first almost completely but after three months was only slightly effective.

Experimentally, benzedrine 20 mg daily gave complete relief from all symptoms. After fourteen months the same dose continued to be fully effective.

CASE 3—G McD, a 19 year old white male student, received a blow on the head in a football game three years before. That night he had an attack of momentary weakness of the legs and fell down. This was followed by attacks of drowsiness and sleep of gradually increasing frequency, until he was having about six attacks daily. He had also momentary generalized weakness whenever he laughed. He had had difficulty with his school work because of these symptoms. Physical examination and neurologic examination were essentially negative. Laboratory studies were negative. The diagnosis was narcolepsy with cataplexy, post-traumatic. Before he was seen by us the patient had taken ephedrine with moderate relief for a short time, followed by rapid diminution in its effectiveness until no relief was obtained.

During this study, he was given 75 mg of benzedrine daily, with complete relief from his sleep attacks and practically complete relief from his cataplectic attacks. He states that he

seven sleep attacks daily. On 90 mg of benzedrine daily for five days she fell asleep on only one occasion. For a period of eleven days she was then given ephedrine in gradually increasing doses up to 242 mg daily, and she fell asleep at least once every day. In a final four day period on 90 mg of benzedrine she fell asleep only once. Complete relief from cataplexy also resulted.

She has been seen since leaving the hospital and six months after beginning benzedrine treatment. She reports complete relief from both sleep attacks and cataplexy.

CASE 5—H M, an 11 year old white schoolboy, had sleep attacks for two years. He had slept all the time he was not actively occupied, also. He had failed his school work because, his teacher said, he could not keep awake. There had been no cataplectic attacks. Physical examination and neurologic examination were essentially negative. Blood and urine examinations were negative. The diagnosis was narcolepsy. Pre-

Comparison of Effectiveness of Benzedrine and Ephedrine in Entire Series of Nine Cases

| Case | Age | Sex | Duration of Disease | Cataplexy | During Experimental Period | | Effectiveness of Benzedrine | Time Followed | Estimated Ratio of Effectiveness of Benzedrine to Ephedrine | Comment |
|------|-----|-----|---------------------|-----------|----------------------------|----------------------------|---|---------------|---|--|
| | | | | | Sleep Attacks Daily | Daily Dose of Ephedrine Mg | | | | |
| 1 | 16 | ♂ | 1 yr | Yes | 3-6 | 92 | Complete relief | 1 month | ? | postencephalitic |
| 2 | 21 | ♂ | 6 yrs | No | 2-4 | 92 | Complete relief for one month then gradual decline, end of 3 months slight relief | 14 months | 4.5:1 | |
| 3 | 19 | ♂ | 3 yrs | Yes | 3-4 | 187 | Complete relief of sleep attacks, nearly complete of cataplexy | 4 months | 2.5:1 | Post traumatic, previously had taken ephedrine with moderate relief for short period followed by no effect |
| 4 | 24 | ♀ | 10 yrs | Yes | 3-6 | 244 | At least one sleep attack daily | 4 months | 2.5:1 | Had ephedrine before beginning this study at first with complete relief but soon began to fall asleep |
| 5 | 11 | ♂ | 9 yrs | No | 3-5 | 48 | At least one sleep attack daily | 4 months | 2:1 | |
| 6 | 34 | ♂ | 10 yrs | Yes | 2-5 | 187 | Only rarely a full day without an attack | 4 months | At least 5:1 | |
| 7 | 18 | ♂ | 3 yrs | Yes | 6-10 | | | 2 months | | Usual dose prevented night sleep and made him extremely irritable and anorexic |
| 8 | 14 | ♀ | 3 yrs | Yes | 3-6 | 92 | Rare attack | 4 months | 1:1 | The two compounds apparently equally effective |
| 9 | 21 | ♀ | 4 yrs | Yes | 3-6 | 244 | At least one attack daily | 2 months | 3.5:1 | Benzedrine at first caused irritability which later disappeared took ephedrine before experimental study at first found 65 mg effective but within a few months found 240 mg of ephedrine not completely effective and had to leave school |

can concentrate on his school work, which he is now successfully completing. He was given ephedrine experimentally, without his knowledge of the change. Single doses of 187 mg of ephedrine were necessary to keep him awake, smaller doses being unsuccessful.

CASE 4—R K, a 24 year old white female houseworker had sleep attacks for ten years occurring from three to six times daily. She also had generalized momentary weakness when she laughed. She had had to give up school because of her symptoms and was doing housework in a friend's home. Physical examination and neurologic examination were essentially negative. Blood, urine and roentgen studies were all negative. The basal metabolic rate had been —14 per cent, —18 per cent, —27 per cent and —25 per cent on different occasions. The diagnosis was narcolepsy with cataplexy. Previous treatment with thyroid extract made her feel better when awake but did not influence the number of sleep attacks. Solution of pituitary was also given, without effect. Ephedrine 100 mg daily, gave some relief but she still slept at least once every day, ephedrine relieved the cataplectic attacks completely.

The patient was hospitalized for study. During a control period on physiologic solution of sodium chloride she averaged

vious treatment with thyroid, 120 mg daily for three weeks, had no effect on his attacks. Sedatives did not relieve his symptoms.

For a control period he was given physiologic solution of sodium chloride and he slept from three to four times daily. He was then given benzedrine, 36 mg and later 24 mg daily, with complete relief from symptoms. When the dose was reduced to 12 mg daily for three days, he fell asleep once a day. On the following two days, during a vacation, he neglected to take any medicine and reported that he "slept all day." During the next eighteen days taking 24 mg of benzedrine daily, he did not sleep except on two occasions when he vomited his dose of medicine immediately after taking it. In the following five days he was given 30 mg of ephedrine daily and slept at least twice each day. For the next nine days he took 48 mg of ephedrine daily and slept at least once each day. Finally, in a period of two weeks on 24 mg of benzedrine, he slept only on two occasions when he neglected to take his dose on time. Eight months after starting treatment he reports that he has fallen asleep only when he has neglected to take his medicine. His teacher reports that he now stays awake in school and will be promoted this year.

CASE 6—H G B, a white man, aged 34, an office worker, had sleep attacks from two to five times daily for the past ten years. He had also had frequent spells of generalized momentary weakness. These attacks of sleep so interfered with his work that he had to give it up. He was unable to concentrate and thought that his memory was failing. An embryoma of the testicle was removed three years before, but there had been no evidence of recurrence or metastasis. Physical examination was essentially negative except for the absence of one testicle. Neurologic examination showed slightly irregular pupils but was otherwise negative. The basal metabolic rate was -17 per cent and -16 per cent. The sugar tolerance curve was normal. Lumbar puncture and skull roentgenograms were negative. The diagnosis was narcolepsy with cataplexy. Ergotamine and caffeine had both been tried experimentally, with no effect. He was given ephedrine 150 mg daily but this was not completely effective since only rarely did he go a whole day without a sleep attack.

Experimentally he was given benzedrine 10 mg daily. He reports that he has had complete relief from all symptoms.

CASE 7—B A, an 18 year old white male student, had from six to ten sleep attacks daily for three years. He also had frequent spells of generalized momentary weakness when he laughed. He had stammered badly since the age of 6, when his handedness was changed from left to right. One sister had epilepsy, one brother stammered. Physical examination was essentially negative. Neurologic examination was negative except for stammering. Diagnosis was made of narcolepsy with cataplexy and strephosymbolic stammering. Atropine and pilocarpine were given with no effect on the narcolepsy.

The patient was hospitalized for study. When he was given 105 mg of benzedrine daily, his daytime sleep attacks were abolished but his night sleep was also interfered with. He became irritable and irascible and there was loss of appetite. On 40 mg of benzedrine daily these untoward symptoms disappeared and he had complete relief from sleep attacks and almost complete relief from cataplexy. He was seen four months after beginning treatment and reported complete relief except when he neglected to take his medicine.

CASE 8—E B, a 14 year old white female student, had a mild head injury three years before. Since then, she had from three to six sleep attacks daily. Whenever she laughed she suffered from momentary generalized weakness. On physical examination there was evidence of mitral stenosis. Neurologic examination was essentially negative. The red blood count was 3,000,000. Lumbar puncture was negative. The diagnosis was narcolepsy with cataplexy, ? post-traumatic, rheumatic heart disease, with mitral stenosis, hypochromic anemia.

The patient was hospitalized for study. During a control period, while taking physiologic solution of sodium chloride she averaged three sleep attacks daily. She was given benzedrine, 80 mg daily, and in a period of several days had only one sleep attack. Again on physiologic solution of sodium chloride she slept twice daily. She was then given ephedrine 115 mg daily, and in a period of a few days had one sleep attack. When again given benzedrine she had no daytime sleep attacks. There was also complete relief from cataplexy.

CASE 9—J C W, a 21 year old white female student, had had sleep attacks from three to six times daily for four years. She had also had momentary generalized spells of weakness associated with laughing. She had been forced to leave college in two successive years because she could not avoid falling asleep in class. Physical examination was essentially negative. Neurologic examination was negative except for ptosis of the right eyelid, which was congenital and familial. Laboratory examinations were negative. The diagnosis was narcolepsy with cataplexy, idiopathic ptosis. Previously, with ephedrine, she got fair relief, though she still fell asleep and had to leave school. She found at first that 65 mg of ephedrine daily was effective, but within three months she had to increase the dose and when first seen was taking from 195 to 250 mg daily and was still falling asleep at least once each day.

Figure 2 is a graphic record of the experiment in this case. The patient was hospitalized for study. During the control period, on physiologic solution of sodium chloride, she averaged four sleep attacks daily. She was given 65 mg of benzedrine daily and had no sleep attacks. She did, however, become

nervous and irritable, but this condition disappeared after two days. Then she was given gradually increasing doses of ephedrine, ranging from 82 to 242 mg daily, and she fell asleep at least once each day. During the final period, on 70 mg of benzedrine daily, she had no sleep attacks. She was seen five months after discharge from the hospital, and she reported that she was not having any sleep attacks at all. She very occasionally had an attack of cataplexy. She felt ready to try going back to college.

Clinical Notes, Suggestions and New Instruments

PAROXYSMAL VENTRICULAR FIBRILLATION

W LAWRENCE CAHALL M D GERMANTOWN PHILADELPHIA

Since ventricular fibrillation is practically always a terminal event, occurring just before clinical death, this case is of interest because of (1) the frequent attacks followed by recovery, (2) the effect of therapy and (3) an unusual electrocardiogram, which recorded one attack that lasted 120 seconds.

T C, a white man, aged 68, admitted to the Germantown Hospital, May 20, 1935, complained of repeated attacks of

Fig 1—A lead 1. Complete heart block with ventricular premature contractions. B lead 2. A short series of ventricular tachycardia. C lead 3. Frequent ventricular premature contractions with a longer run of ventricular tachycardia terminated in D.

unconsciousness. These had begun only three days before, although he had had occasional vertigo and increasing dyspnea for the past year. The past medical history was negative. Physical examination was negative except for moderate gen-

Fig 2—A the first QRS complex seen is followed by the onset of ventricular fibrillation. A continuous strip of lead 2 was taken. B is cut from a section twenty seconds later. C at sixty seconds and D at the termination of the attack passing from fibrillation to ventricular tachycardia and return to the dominant rhythm complete heart block. The entire episode measured 120 seconds.

eralized arteriosclerosis. Cardiac examination showed slight enlargement to the left. The heart sounds indicated poor muscular quality. A soft systolic murmur was heard at the apex. The blood pressure was 190-200 systolic, 100 diastolic. The heart rate was from 34 to 40 with frequent premature contractions. There were no signs of congestive failure. Ur-

analysis revealed a specific gravity of 1.022, a trace of albumin and numerous white blood cells. A blood count revealed slight polymorphonuclear leukocytosis. The Wassermann reaction was negative. Blood sugar and urea nitrogen were normal. Roentgenograms showed old fibrosis of the lung fields and slight cardiac enlargement.

During the first twenty-four hours he had eighteen attacks of ventricular fibrillation ranging from twenty to forty seconds. He would become ashen, his eyes would take on a fixed, glassy stare, respirations would cease, the pulse would disappear, no heart sounds could be heard over the precordium reflexes would be absent and there would be a loss in sphincter control. Then feeble rapid heart action could be detected becoming stronger, respirations commence and consciousness return and the heart would slow down to the usual rate of 32 to 36 per minute.

Figure 1 shows complete heart block with frequent ventricular tachycardia. Sedatives had no effect on lessening the frequency of the attacks, so on May 22, 5 minims (0.3 cc.) of epinephrine was given intramuscularly third hour. There was a prompt obliteration of the premature contractions that always preceded a paroxysm of ventricular fibrillation and cessation of further attacks. May 24, 2 grains (0.12 Gm.) of quinidine sulfate was given the fourth hour and May 25 and 26, 4 grains (0.24 Gm.) four times a day. Premature contractions reappeared and the paroxysms of ventricular fibrillation recurred, becoming more frequent and longer in duration. One attack was observed on the 26th, during which no heart action could be detected for over three minutes. Another was recorded as shown in figure 2.

The quinidine was stopped and 5 minims of epinephrine was again given every third hour, with prompt cessation of attacks after the first dose and were not repeated. Epinephrine was stopped June 1 and he was entirely free until his discharge from the hospital, June 8, in good condition. Further electrocardiograms showed no appreciable change in the complete heart block and only a rare premature contraction. He continued to do well at home, was stronger, had less dyspnea and no return of attacks until six weeks later, when he was found dead presumably in a final paroxysm. Autopsy was not obtainable.

COMMENT

There is a divergence of opinion in regard to the use of epinephrine, quinidine and digitalis in paroxysmal ventricular fibrillation.

Davis and Sprague¹ believe that a circus movement in the ventricles is responsible for the arrhythmia. When there is complete auriculoventricular dissociation, the slow rate of complete heart block is initiated by the idioventricular node. If frequent ectopic ventricular premature contractions are present, ventricular fibrillation may supervene. Both quinidine and digitalis depress intraventricular conduction time in the branch bundles and Purkinje fibers so the administration of these drugs increases the hazard in complete heart block.

Dock² reports a case which was initiated by epinephrine and controlled by quinidine. Kerr and Bender³ feel that quinidine was the causative factor in their case.

Other observers⁴ have been successful in controlling paroxysms of ventricular fibrillation by intramuscular injection of epinephrine. Levine and Matton⁵ report a case in which recovery followed the intracardiac injection of epinephrine.

On the other hand, Schwartz and Jezer⁶ believe that epinephrine is distinctly contraindicated since it enhances the

irritability of the ventricles and stimulates the idioventricular pacemaker. However, in their experiments no premature contractions were noted during the use of epinephrine. In the case here reported, each paroxysm was preceded by an increasing number of premature contractions.

Obviously no conclusions can be drawn from single cases, but from the clinical observations in this case epinephrine would seem to be indicated to abolish these ectopic beats and quinidine contraindicated if complete heart block is present.

FOOD, DRUG, THERAPEUTIC DEVICE AND COSMETIC LEGISLATION PENDING IN CONGRESS

A CRITICAL ANALYSIS OF THE PROVISIONS OF THE COPELAND BILL¹ RELATING TO DRUGS AND PROPHYLACTIC AND THERAPEUTIC DEVICES

By THE BUREAU OF LEGAL MEDICINE AND LEGISLATION, AMERICAN MEDICAL ASSOCIATION CHICAGO

The Federal Food and Drugs Act of 1906 was enacted nearly thirty years ago. Inherent weaknesses were recognized in it at that time, but there had been a long hard battle for even such legislation as was then in prospect and its proponents accepted the new act as the best they could get. Amendatory legislation, they hoped, would strengthen and supplement it. Some such legislation has been enacted in the long period that has elapsed since that time, but at the end of thirty years the act is recognized as an ineffective remedy for the evils that it was intended to cure and for others that have grown up.

Today a situation confronts us similar to that which confronted the proponents of federal food and drug legislation thirty years ago. The country is engaged in a struggle to procure the enactment of federal legislation adequate, when taken into consideration with the numerous other federal food and drug laws, to protect the people against fraud and against danger to health, inherent in the inadequately supervised and controlled manufacture and sale of foods and drugs, prophylactic and therapeutic devices, and cosmetics, so far as it lies within the power of the federal government to enact such legislation. Emulating the proponents of earlier legislation, the proponents of the legislation now pending, in their eagerness to procure its enactment, have made so many concessions to commercial interests, as distinguished from the interests of the consumer, that the prospect of effective legislation has been greatly diminished. There is grave danger of the enactment of an inadequate law—one that will not protect the consumer adequately, that will require expensive and prolonged litigation before it can be effectively enforced, and that may for another quarter century or more exclude from the statute books an effective law. The situation must be met now, by adequate amendments of the Copeland bill, or by the preparation of a new bill.

1 Seventy Fourth Congress S. 5 'An Act To prevent the adulteration, misbranding and false advertising of food, drugs, devices and cosmetics in interstate foreign and other commerce, subject to the dictation of the United States for the purposes of safeguarding the public health, preventing deceit upon the purchasing public and for other purposes.

Circumstances prevent an analysis of each of the nine bills now pending in Congress for the better regulation of the manufacture and sale of foods, drugs, devices and cosmetics. The outstanding bill is S 5, commonly referred to as the Copeland bill, it is sponsored by a senator who is a physician, it has passed the Senate, and it has been made the principal topic of discussion in the hearings held under the auspices of a subcommittee of the Committee on Interstate and Foreign Commerce of the House of Representatives. Because of its length and breadth, however, and its wealth of detail, it is impossible to give here a critical analysis even of that one measure in its entirety. This analysis will be limited, therefore, to the provisions of the Copeland bill that relate primarily to drugs and prophylactic and therapeutic devices. These are the provisions that are of primary import to the medical profession and unfortunately are probably the weakest in the bill.

Adequate standards of purity, wholesomeness and potency of foods, drugs, prophylactic and therapeutic devices, and cosmetics constitute the foundation of legislation to protect the people from fraud and from danger to health in the purchase and use of such merchandise. Adequate standards of frankness and truthfulness in labeling and advertising are likewise important. Without standards, compliance by the honest manufacturer, distributor and dealer is difficult, evasion by the dishonest is easy, administrative officers and the courts are embarrassed in their efforts to enforce the law, the cost of enforcement is increased, and the consumer suffers. So far as relates to drugs and prophylactic and therapeutic devices, the Copeland bill proposes no adequate standards.

SCOPE OF COPELAND BILL

The Copeland bill defines interstate and foreign commerce so as to make it cover not only interstate and foreign commerce, properly so called, but also commerce in the District of Columbia and the territories. The bill covers four classes of merchandise whenever and wherever they enter such commerce, namely, (1) foods, (2) drugs, (3) devices and (4) cosmetics. It proposes standards of purity and safety for foods, drugs and cosmetics, and regulations to govern the labeling and advertising of them and of devices. For foods, the Secretary of Agriculture is to be authorized to set up additional standards. For drugs, three private organizations are to have similar authority, namely, the United States Pharmacopoeial Convention, Inc., the American Institute of Homeopathy, and the American Pharmaceutical Association.

STANDARDS FOR DRUGS AND DEVICES

The Copeland bill proposes to set up certain standards of purity and potency for drugs. It proposes no standards for the soundness and potency for what the bill dominates as "devices." The labeling and advertising requirements with respect to both of these classes of merchandise are identical, so far as they are applicable to one or to the other or to both. Drugs and devices, therefore, may be considered together.

"Drugs" and "Devices" Defined—For the purposes of the bill, the term "drug" and the term "device" are defined as follows:

Section 201 As used in this Act, unless the context otherwise indicates

(b) The term "drug," for the purposes of this Act and not for the regulation of the legalized practice of the healing art includes (1) all substances and preparations recognized in the

United States Pharmacopoeia, *Homoeopathic Pharmacopoeia of the United States*, or National Formulary, or any supplement to any of them, and (2) all substances and preparations intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man or other animals, and (3) all substances, and preparations, other than food and cosmetics, intended to affect the structure or any function of the body. [2 3-19]

(c) The term "device," for the purposes of this Act and not for the regulation of the legalized practice of the healing art, includes all devices intended (1) for the use in diagnosis, cure, mitigation, treatment, or prevention of disease in man or other animals, and (2) to affect the structure or any function of the body. [2 20-25]

The foregoing definitions, it will be observed, are only "for the purposes of this Act," and "not for the regulation of the legalized practice of the healing art."

The phrase "not for the regulation of the legalized practice of the healing art" is used, according to the Senate Committee on Commerce,² "to make it clear that the bill is not a medical practices act and will not interfere with the practice of the healing art by chiropractors and others in the States where they are licensed by law to engage in such practice." Its full import is best understood when it is remembered that in certain states some practitioners are licensed on condition that they shall not use drugs and in some states chiropractors are limited in their practice to palpation and adjustments of the vertebrae and possibly of other tissues by hand only. If any practitioner holding such a limited license uses drugs or any chiropractor licensed to use only manual palpation and adjustment uses mechanical devices of any kind, he is guilty of violating the medical practice act and may be punished accordingly. The apparent purpose of the limiting phrase "and not for the regulation of the legalized practice of the healing art" is to prevent the law enforcement officers of any state from introducing in evidence the proposed federal definitions of "drug" and of "device" to show that a substance administered or prescribed by a supposedly drugless practitioner is in fact a drug, or to show that a device used by a chiropractor who is authorized to use only his hands is in fact a device and not a negligible incident to manual diagnosis and treatment. The limiting clause will therefore apparently tend to facilitate the fraudulent practice of drugless healing, favoring particularly chiropractic.

"Misbranding" and "False Advertisement" Defined and Prohibited—The Copeland bill proposes to penalize misbranded drugs and devices in interstate commerce and the dissemination of false advertisements of drugs and devices in interstate commerce and in the mail. The adequacy of these prohibitions depends on the meaning of the words "misbranded" and "false" as used in them.

"Misbranded" is defined by the bill as follows:

Sec 402 A drug or device shall be deemed to be misbranded—

(a) If its labeling is false or misleading in any particular. Any representation concerning any effect of a drug or device shall be deemed to be false under this paragraph if such representation is not supported by demonstrable scientific facts or substantial and reliable medical or scientific opinion.

Under the heading "False Advertisement," the bill says:

Section 601 (a) An advertisement of a food, drug, device, or cosmetic shall be deemed to be false if it is false or misleading in any particular relevant to the purposes of this Act regarding such food, drug, or cosmetic. Any representation concerning any effect of a drug or device shall be deemed to be false under

this paragraph if such representation is not supported by demonstrable scientific facts or substantial and reliable medical or scientific opinion

The limiting sentences in both of the foregoing definitions, it will be noted, have reference solely to representations concerning the effects of drugs or devices, as the case may be. Seemingly they are intended to limit the activities of the manufacturers and venders of unworthy and unfit drugs, notably the manufacturers and venders of quack medicines. As a matter of fact, however, when interpreted in the light of the bizarre definitions of the terms "medical opinion" and "scientific opinion" embodied in the act, and as construed by the Senate Committee on Commerce, they open the door wide for fraud and danger. When it is proposed that a representation concerning the effect of a drug or device shall be deemed to be false if it is not supported by demonstrable scientific facts or substantial and reliable medical or scientific opinion, it is clearly implied that such a representation is not to be deemed false but is to be deemed true if it is so supported. And the language of the bill is such that such a representation need be supported only by (1) demonstrable scientific facts or (2) substantial and reliable scientific opinion, or (3) substantial and reliable medical opinion. In other words, even though representations concerning the effect of a drug or device are not "supported by demonstrable scientific facts," and even though they may be disproved by such facts, they are, for the purposes of this bill, to be accepted as true if they are supported by "substantial and reliable scientific or medical opinion" as that term is defined by the bill, a matter that will be discussed later. In the end, a lay jury will in contested cases judge the weight of the evidence and determine whether any of the medical or scientific opinions offered in evidence are "substantial and reliable." Obviously, the results will be uncertain.

Moreover, the bill seems to throw the burden of proof on the government, for the defendant is entitled to the presumption of innocence and before he can be convicted it must be shown beyond a reasonable doubt that a representation that he has made concerning the effect of a drug or device and that the prosecution alleges is false is not supported by demonstrable scientific facts or by substantial and reliable scientific or medical opinion. The difficulty and expense of successful prosecutions under such conditions can easily be seen. The proof of a negative is notoriously difficult, it may easily be impossible in cases arising under the foregoing provisions of the Copeland bill, if the construction placed on them by the Senate Committee on Commerce is accepted, for as construed by the committee any such representation supported by the opinion of any "numerically significant group of competent and reliable practitioners or qualified scientists, including recognized experts in the field in question," is not to be deemed false.³ How numerous a group must be before it becomes "numerically significant," the committee has not said. Presumably, however, there may be numerous "numerically significant groups" in any state, territory or other jurisdiction.

The difficulty of obtaining a proper judgment under this bill as to the truth or falsity of any representation concerning the effect of a drug or device is increased by the attempts made in the bill to define arbitrarily the terms "scientific opinion" and "medical opinion."

"Scientific Opinion" Defined—For the purposes of the bill, "scientific opinion" is limited to "the opinion, within their respective fields, of competent pharmacologists, physiologists, or toxicologists." The opinions of biologists, chemists, physicists and psychologists, and of experts in all branches of these sciences and arts, are to go for naught as "scientific opinion" unless the witness whose evidence is proffered dubs himself or is dubbed by others as a "pharmacologist," a "physiologist" or a "toxicologist."

'Medical Opinion' Defined—In contradistinction to the foregoing narrow definition of "scientific opinion," the definition of the term "medical opinion" opens a wide field.

The term "medical opinion" means the opinion within their respective fields of the practitioners of any branch of the medical profession the practice of which is licensed by law in the State or Territory where any drug or device, to which such opinion relates is held, sold, or distributed.

The meaning of this definition is hidden in the bill's arbitrary definition of the seemingly simple term "medical profession," for the bill provides

The term "medical profession" means the legalized professions of the healing art.

Unfortunately, the bill leaves us in the dark as to what it means by the phrase "the legalized professions of the healing art." According to the Senate Committee on Commerce—

The definitions of "medical profession" and "medical opinion" in paragraph (k) [sic] are intended to effect a definite recognition of all branches and divisions of the healing art which are licensed by law in the various States and Territories, and to provide that statements concerning the effect of drugs and devices shall be judged on the basis of the opinion of the branch of the healing art in accordance with the teachings of which they are offered. It is further intended that the laws governing medical practice of the State or Territory in which the drug is to be distributed shall prevail in determining whether the opinion of any particular branch of the healing art may be resorted to in the trial of issues arising under this act. The definition as so drawn recognizes fully the right of the States to determine for themselves, through their control of medical practice, the character of representations made for drugs and devices coming from interstate commerce for distribution within their own borders.⁴

The term "medical opinion" seems to mean, then, wherever it appears in the Copeland bill, the opinions not only of doctors of medicine and of dentists, pharmacists and registered nurses but the opinions also of chiropractors, osteopaths, naturopaths, optometrists, chiropodists and midwives, and in some states of other practitioners according as one or another class is licensed by the laws of the state. Just how the court is to determine whether any particular drug or device is or is not within the field of any one group, or in the fields of two or more of them, and how the jury is to determine what constitutes substantial and reliable "medical opinion" when a drug or device may be within the fields of two or more such groups, are problems that the bill leaves to the courts, to solve as best they can.

The situation with respect to the misbranding of drugs and devices and the false advertising of drugs and devices may be summed up as follows. A drug or device is to be deemed misbranded if its labeling is false or misleading in any particular, and an advertise-

³ Seventy Fourth Congress S Rep 646 p 6

⁴ Seventy Fourth Congress S Rep 646 p 2

ment of a drug or device is to be deemed false if it is false or misleading in any particular relevant to the purposes of the act regarding such drug or device, except that no representation concerning any effect of a drug or device is to be deemed false if it is supported by demonstrable scientific facts, or substantial and reliable scientific opinion, or substantial and reliable medical opinion. A representation that finds support from any one of these sources is not to be deemed false, no matter how thoroughly it may be discredited by evidence from the two other sources named in the bill. Scientific opinion is to be limited to the opinions of pharmacologists, physiologists and toxicologists. Medical opinion is to include the opinions not only of doctors of medicine and of dentistry, pharmacists, and nurses and licensed chiropractors but also of osteopaths, chiropractors, naturopaths, optometrists, midwives and possibly others concerning any drug or device that lies within the field of practice that the witness is authorized by law to pursue. The scientific opinion and the medical opinion sufficient to support any representation and save it from being legally false is not the preponderance of scientific opinion or medical opinion throughout the United States or even within any one state but is, in any state or territory nothing more than the opinion of any "numerically significant group" within that particular state or territory.

Tracing our way back, then, through the maze of definition and subdefinition embodied in the Copeland bill, we find that no matter how effectively a representation concerning the effect of a drug or device is disproved by scientific facts and opinions such disproof will not prevent the use of that representation in advertising and labeling, for the exploitation of that drug or device when it is sold in interstate and foreign commerce in any state, the District of Columbia or any territory, in which the misrepresentation is supported by the opinions of any "numerically significant group" of "practitioners of any branch of the medical profession," be they doctors of medicine, dentists, pharmacists, midwives, physiotherapists, optometrists or osteopaths, within their respective fields of licensed activity. So-called medical opinion, as it varies from time to time and from place to place in our fifty-four states, territories and other primary jurisdictions, is to determine what constitutes "misrepresentation", and the manufacturer, distributor, dealer and consumer, and even the prescribing physician, must discover what that opinion is from day to day as best he can, at his own peril. But so long as a drug or device has the approval of any proper numerically significant group in a jurisdiction, it can lawfully be sold in that jurisdiction, in interstate commerce, no matter what the opinions of other equally or even more significant groups in the same community and throughout the world may think.

Misbranding That Injures or Kills Only by Delaying Treatment Is to Be Tolerated—The insufficiency of the standards proposed by the Copeland bill with respect to the labeling and advertising of drugs and devices is aggravated by the following provision in the bill

Sec 402 A drug or device shall be deemed to be misbranded—

(b) If it is dangerous to health under the conditions of use prescribed in the labeling or advertising thereof

It must be rare, indeed, that a manufacturer, distributor or vender of quack medicines and devices cannot phrase the directions for use that he inserts in his

labeling and advertisements so as to prevent his nostrum or device from being directly and positively "dangerous to health under the conditions of use prescribed in the labeling or advertising." With negative danger, as we shall see, injuring and killing by delaying proper treatment, the foregoing provisions of the Copeland bill are apparently not concerned.

Some protection is afforded by the requirement that, if a medicine contain any one or more of certain named habit forming drugs, the label shall declare that the medicine "May be habit forming." As an additional safeguard the bill proposes to require that the name of each active ingredient of a medicine, although not the proportions of each of the ingredients, be stated on the label. It proposes to require also that the labeling of any drug or device contain complete and adequate directions for use and adequate warnings against (1) use in particular conditions, (2) use by children, and (3) excessive or prolonged use and unsafe methods or dosage. But no such warning and information need be embodied in any advertisement.

On the other hand, the bill proposes to forbid the incorporation, in any advertisement of any drug or device, of representations as to its therapeutic effect in the treatment of Bright's disease, cancer, tuberculosis, infantile paralysis, venereal diseases, and heart and vascular diseases, but apparently representations of such therapeutic claims may be freely made in the labeling, if supported in the manner already described. Even the prohibition of the publication of therapeutic claims in advertisements does not apply in the case of the retail dealer who disseminates "in good faith" any advertisement, no matter how false it may be, offering for sale at his place of business any article that he does not distribute or sell in interstate commerce.

The language of the Copeland bill, set forth in the foregoing, has been given a most unhappy, unfortunate and unexpected meaning by the Senate Committee on Commerce. Unfortunately, the construction that the committee placed on the bill was made in such a way as to render it possible for it to be consulted and relied on by the courts, if doubt is thrown on the intent of Congress with respect to these particular provisions of the bill. The bill proposes, as has been pointed out, penalties for the introduction into interstate commerce of any misbranded drug or device, for the misbranding of any such drug or device in interstate commerce and for the receipt in interstate commerce of any drug or device so misbranded, and it provides for the seizure of any such misbranded drug or device. According to the Senate Committee on Commerce, however, these provisions of the bill are not to be construed to prevent such misbranding of drugs and devices as are calculated to injure and kill only by causing delay in the adoption of rational methods of treatment. Neither the bill nor the report of the Senate Committee on Commerce that accompanied it, May 22, 1935,⁵ gave any clue of this limitation on the meaning of the language quoted. On May 28, 1935, however, the chairman of the Committee on Commerce, Senator Copeland, asked and obtained the unanimous consent of the Senate to amend the report of the committee as previously filed and printed, by inserting the following

Much criticism has been launched at this provision on the ground that it applies to innocuous drugs for which extravagant therapeutic claims are made and which thus indirectly impair the patient's chance of recovery through his postponement of

*proper methods of treatment The language does not relate to such products It applies only to potent drugs which are per se harmful unless properly administered*⁶

In order that there might be no possibility of misunderstanding regarding the matter, the report of the committee was at the same time amended by striking from the following paragraph in the original committee report the language reproduced in italics

It is intended that the Government shall have authority to proceed with multiple seizures against any adulterated product. It is likewise intended that the Government may make multiple seizures of any misbranded product, whether it is per se poisonous or not, if it is misbranded in such a fashion that imminent danger to the health of the consumer is involved. *Such danger might result from improper or insufficient directions for use of a potent drug, it may also follow the misbranding of an innocuous drug with false claims for a serious disease, which induce the patient to delay effective treatment until too late. In the latter example, the product of itself, if honestly sold, would not in any way endanger health but even though it is innocuous, it may very definitely endanger health through misrepresentations made for it*

The amending of the report of the Senate Committee on Commerce in the manner stated, with the full knowledge of the Senate itself, may not unreasonably be construed by the courts as indicating an intent on the part of the Senate that, except so far as the bill proposes to forbid advertisements for the treatment of certain named diseases, it shall not interfere with the labeling and advertising of "patent" and proprietary medicines and devices that are misleading as to the effects of such medicines and devices, so long as they do not harm directly but aggravate disease and injury and hasten death only by leading the patient to refrain too long from seeking proper treatment. In other words, labeling and advertising that recommends the use of a drug or device not inherently dangerous, for the relief of cough, with lassitude and diminishing weight, is not to be forbidden, even though its use may delay diagnosis and rational treatment and end in death from tuberculosis. A drug, not in itself inherently dangerous, may, under the provisions of this bill as construed by the Senate committee, be lawfully labeled and advertised for the scattering of "lumps in the breast," although by its use diagnosis and rational treatment are delayed and the patient dies of cancer when an early operation would have saved her life.

Pharmacopoeial and Formulary Standards Optional and of Doubtful Validity—If the provisions of the Copeland bill are unsatisfactory so far as they relate to drugs and devices generally, those that relate specifically to drugs of what may be termed official types, such as those covered by the United States Pharmacopoeia and the National Formulary, are no better. Those provisions are based primarily on the proposed statutory definition of the term "official compendium." The bill defines that term as follows:

Section 201 As used in this Act, unless the context otherwise indicates

(m) The term "official compendium" means the United States Pharmacopoeia, Homeopathic Pharmacopoeia of the United States, National Formulary, or any supplement to any of them, official at the time any drug to which the provisions thereof relate is introduced into interstate commerce.

This proposed definition, if adopted, will introduce two standards for drugs not now recognized by law, namely, (1) the Homeopathic Pharmacopoeia of the United States and (2) "supplements" to the United States

Pharmacopoeia, the Homeopathic Pharmacopoeia of the United States and the National Formulary

So far as is known, the fact that the Food and Drugs Act of 1906, for the past thirty years, has not officially recognized the Homeopathic Pharmacopoeia has caused no trouble. No edition of that pharmacopoeia has been published since 1914. What motivates the proposed recognition now of such an archaic volume it is impossible to understand. The situation is not improved by the provision that an agency, not named in the bill, but easily identified as the American Institute of Homeopathy, is to be authorized to publish from time to time "supplements" to this pharmacopoeia.

After having defined the term "official compendium," the bill proceeds to establish standards for official drugs.

Section 401 A drug shall be deemed to be adulterated

(b) If its name is recognized in an official compendium, or if it purports to be a drug the name of which is so recognized and it differs from the standard of strength, quality, or purity as determined by the tests or methods of assay set forth therein, except that whenever tests or methods of assay have not been prescribed therein, or such tests or methods of assay as are prescribed are insufficient, for determining whether or not such drug complies with such standard, the Secretary is hereby authorized to bring such fact to the attention of the *appropriate body charged with the revision of such compendium* and if such body fails within a reasonable time to prescribe tests or methods of assay which are sufficient, then the Secretary may prescribe for the purposes of this Act such tests or methods of assay by regulations as provided by sections 701 and 703. *No drug shall be deemed to be adulterated under this paragraph because it differs from the standards of strength, quality, or purity therefor set forth in an official compendium, if its standard or [sic] strength, quality, and purity be plainly stated on its label*

This attempt at the establishment of drug standards gives rise to two questions. 1. Has Congress the right to delegate to unnamed publishers of the volumes that it designates as "official compendiums," and to unnamed publishers of "supplements" to such volumes, the right to fix legal standards for drugs, binding on every one throughout the United States? 2. Of what legal effect are the standards proposed by the bill, since every one is to be at liberty to adopt any standards of strength, quality and purity for any drug named in the pharmacopoeia or formulary, provided only that he states his private standards on the label?

Attempted Delegation of Legislative Authority—Has Congress the right to delegate to unnamed publishers of the volumes that it designates as "official compendiums," and to unnamed publishers of "supplements" of such volumes, the right to fix legal standards for drugs, binding on every one throughout the United States? One of the so-called compendiums the standards of which, present and future, it is proposed to adopt as legal standards, is the United States Pharmacopoeia. It is published by a private corporation, the United States Pharmacopoeial Convention, Inc. Another, the Homeopathic Pharmacopoeia of the United States, is published by another private organization, the American Institute of Homeopathy. The third, the National Formulary, is published by a private organization, the American Pharmaceutical Association. Nowhere in the bill does the name of any of these organizations appear. They are referred to severally only as "the appropriate body charged with the revision of such compendium," but the bill nowhere charges anybody with any such duty. The bill imposes no limit on the right of the publishers of these compendiums to make and alter standards at pleasure, except that the Secretary of Agriculture may prescribe tests or methods of assay and packaging, if

after due notice the publishers fail to correct what he believes are defects in the tests or methods of assay and packaging previously prescribed by them. The bill lays down no lines of separation between the jurisdictions of these three organizations. It imposes on none of them any obligation to give notice of the proposed establishment of standards or of changes in existing standards, or to give hearings, or to publish in any prescribed manner or at all the standards prescribed.

The legal aspects of such an attempted delegation of ill defined legislative authority to unidentified agencies can hardly be discussed here, but such a delegation is believed to be clearly unconstitutional. The fact that the Food and Drugs Act of June 30, 1906, as amended, contains a similar provision, does not justify its incorporation in the Copeland bill. So far as is known, no serious attack on the standards in the present law has ever been made, but where attacks have been made on similar provisions in state food and drug acts, the courts have held, except in one instance, that the standards proposed in the state act in question were only those previously prescribed in the United States Pharmacopeia or the National Formulary and official at the time the act was passed. That a legislative body can lawfully incorporate in law standards in existence when the law is enacted is clear but that it cannot distribute among three unnamed private agencies an unrestricted authority to fix future standards, without the necessity of notice of hearing, or even publication, seems equally clear.

Of what legal effect are the standards proposed by the bill, since every one is to be at liberty to adopt any standard of strength, quality and purity for any drug named in the pharmacopeia or formulary, provided only that he states his private standards on the label? Possibly for the purpose of preventing a legal attack on the constitutionality of the privately made standards for drugs, proposed by the Copeland bill, the bill specifically provides that no body need comply with them, saying

No drug shall be deemed to be adulterated under this paragraph because it differs from the standards of strength, quality, or purity therefor set forth in an official compendium, if its standard or [sic] strength, quality, and purity be plainly stated on its label.

The foregoing provision, authorizing all manner of variations from what at first glance appear to be official standards, is intended, it has been suggested, to preserve the constitutionality of the attempted delegation of legislative authority. If it seems to accomplish that end, it probably does so only because it makes it worth no one's while to test the issue in court. Probably the existence of a similar exempting clause in the Food and Drugs Act of 1906 is a reason why the constitutionality of the delegation of legislative authority attempted in that act has never been tested in court.

It has been urged that too rigid standards for drugs would retard progress and that an exempting clause such as is here proposed is necessary to permit advances to be made. This argument seems to lose sight of the fact that, if the provisions of this bill are valid, there will always be three organizations that can give immediate effect to any improvement in drugs, without any formality whatever, by the simple process of issuing a "supplement" to any one of the so-called official compendiums. As the bill is written, it proposes to make every pharmacist in the United States, wholesale and retail, the sole judge, so far as his own products are concerned, of what constitutes an improvement or advance in pharmacologic and therapeutic technique. Finally, although the drug standards in this bill, relating

to such drugs as are covered by the pharmacopeias and formulary, will probably be declared unconstitutional as soon as the issue is raised, the bill makes no provision whatever whereby adequate standards may be set up by some duly constituted authority if such a situation should arise.

Labeling Requirements for Drugs Illogical and Inadequate—While the Copeland bill proposes no adequate standards for purity and potency of drugs, it prescribes requirements for labeling that in some cases are unnecessary and in others may do harm rather than good. The Food and Drugs Act of 1906 provides that drugs shall be deemed misbranded if the package fails to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, cocaine, heroine, alpha or beta eucaine, chloroform, cannabis indica, chloral hydrate, or acetanilid, or any derivative or preparation of any of them (section 8, subsection "In case of drugs," paragraph second). The Copeland bill requires no such disclosure. It provides that if a drug is fabricated from two or more ingredients, the name of each active ingredient, including alcohol, shall appear on the label, unless the Secretary of Agriculture deems it impracticable, but it does not require that the quantity or proportion of the several drugs be stated. Obviously, the listing of the name of a potent, dangerous drug along with the name or names of one or more relatively innocuous drugs would give the purchaser no idea of the potency of the mixture. Innocuous drugs, under this bill, would probably be introduced into quack medicines for the sole purpose of using their names on the label to obscure the presence and effect of really potent drugs, like acetanilid or the barbituric acid compounds. The bill does contain a lengthy list of drugs the presence of which makes necessary a statement on the label that the drug or mixture "May be habit forming" but acetanilid and alcohol are not among the drugs so listed.

The general labeling requirements for drugs make no exception in favor of physicians' prescriptions, except that they authorize the omission of the warning phrase "May be habit forming." Even though adequate directions for use appear on the label, a physician's prescription, if it calls for a drug not designated solely by a name recognized in a so-called official compendium must be labeled so as to show the common or usual name of the drug, if there is any, and, unless the Secretary of Agriculture by special dispensation otherwise provides, if the prescription calls for two or more ingredients, the label must show the name of each active ingredient, including any alcohol it may contain. A container in which a pharmacist has dispensed a physician's prescription or any other drug whatever—even so innocent a drug as sodium bicarbonate—must be labeled so as to give "warnings in such manner and form as may be adequate against use in such pathological conditions or by children where its use may be dangerous to health, or against unsafe dosage or methods or duration of administration or application" and, unless the secretary deems directions for use unnecessary for the protection of the public health, the label must contain also complete and adequate directions for use. Whether the required directions for use are to be "complete and adequate" for the purposes of the immediate purchaser of the drug, or "complete and adequate" for all purposes for which the drug may possibly be put, the bill does not say. Apparently, if the Copeland bill should be enacted in its present form, a new and elaborate system of labeling all manner of

PROMULGATION OF REGULATIONS

The Food and Drugs Act of 1906 provides for the promulgation of regulations by a board consisting of the Secretary of the Treasury, the Secretary of Commerce and the Secretary of Agriculture (section 3). These three officers, through the resources of their respective departments, have access to all information necessary for the framing of such regulations as the act requires. The Secretary of the Treasury, through the Bureau of Public Health Service, is in touch with matters relating to public health, and the Bureau of Customs keeps him in touch with foreign trade. The Secretary of Commerce, through the Bureau of Standards, has access to the best and latest scientific information regarding standards and methods of assay, and the Bureau of Fisheries serve to keep him in touch with problems relating to manufacture and industry and with one aspect of food production. The Secretary of Agriculture has in his jurisdiction the Bureau of Animal Industry, the Bureau of Dairy Industry, the Food and Drug Administration and other agencies concerned with production and distribution of food and drugs.

The Copeland bill, however, proposes to break down this admirably organized board for the promulgation of regulations by eliminating from it the Secretary of the Treasury and the Secretary of Commerce. The bill proposes to set up, it is true, a committee on food standards and a committee on public health, appointed by the President, to assist in the promulgation of regulations. Without questioning the advisability of setting up a committee on food standards, it may well be pointed out that such a committee can cooperate just as effectively with such a board as now exists for the promulgation of regulations as it can with the Secretary of Agriculture alone. It must be frankly stated, however, that there seems to be no reasonable good to be obtained by the establishment of the proposed committee on public health, in the Department of Agriculture, independent of the recognized public health agency of the country, the United States Public Health Service, particularly at a time when the President has only recently felt called on to appoint a committee for the purpose of better coordinating and making more effective the health agencies that now exist.

ENFORCEMENT OF LAW

If the standards for drugs and the provisions with respect to the labeling and advertising of drugs and devices, laid down in the Copeland bill, are weak, that weakness is not likely to be offset by severity in the enforcement provisions of the bill. Probably in no other statute authorizing and providing for the punishment of crime has there ever been incorporated a provision specifically leaving to the discretion of the enforcing officer the determination whether he will or will not enforce the penalties that it provides without any reference even to any "offer in compromise" or other quasipunitive adjustment. The Copeland bill, however, says that—

Nothing in this Act shall be construed as requiring the Secretary to report for prosecution or for the institution of libel injunction proceedings, or civil penalty action minor violations of this Act whenever he believes that the purposes of the Act can best be accomplished by a suitable written notice or warning.

The standards by which the secretary is to determine whether a violation of the act is a "minor" or a "major" violation are not stated nor is the secretary required to state them in regulations. Whether he will or will

not institute prosecution in any case is left to his discretion in that very case, and he need give to no one his reasons for not prosecuting or make any record of those reasons. As the matter of instituting prosecutions or refraining from instituting them will not be passed on primarily by the Secretary of Agriculture himself but by subordinate officers in the Department of Agriculture, the danger of this provision is apparent.

The secretary must go through a long process, too, before venturing to initiate proceedings against any offender, except as relates to certain seizures that he is authorized to make. He must first serve or cause to be served on the supposed offender an appropriate notice and give to him an opportunity to be heard, and hearings must be conducted by the secretary of an officer or employee designated by him. Even after such a hearing and a tentative decision based on it, the secretary, before proceeding to prosecute, must report his tentative decision to the supposed offender and give him an opportunity to show cause why he should have a second hearing. Until after all this has been done, and until after a second hearing has been given, if the secretary believes that a second hearing is necessary, prosecution cannot be instituted.

The bill places a premium on a dealer's ignorance, when it provides that no dealer shall be liable to the fine and imprisonment prescribed by it, for having received in interstate commerce any article of food, drug, device or cosmetic and having "in good faith" sold it as received, unless he refuses to furnish on request the name and address of the person from whom he purchased or received such article and the documents pertaining to the delivery of the article to him. The dealer who remains ignorant of the quality of the goods that he sells and concerning the labeling and advertising of them can sell them "in good faith," even though they are in fact adulterated, misbranded and falsely advertised, and then avoid punishment by the simple expedient of furnishing, on request, the name of the person from whom he obtained such goods and the documents pertaining to their delivery. If a dealer takes the trouble to inform himself concerning the merchandise he handles, he will not be able lawfully to sell it. Furthermore, a dealer who is engaged in a retail business cannot lawfully be even prosecuted under this bill for the dissemination, "in good faith," of an advertisement offering for sale at his place of business any article which he does not distribute or sell in interstate commerce, although it is unlawful to disseminate similar advertisements in the mail, or in interstate commerce, by radio broadcast or otherwise, or by any means, for the purpose of inducing directly or indirectly the purchase of food, drugs, devices or cosmetics in interstate commerce.

Finally, it may be questioned whether the Copeland bill does not unduly restrict the dissemination of information by the Secretary of Agriculture concerning food, drugs, devices and cosmetics. The secretary must, it is true, cause to be published reports summarizing all judgments, decrees and court orders that have been rendered. Moreover, there is nothing to prevent the secretary from collecting, reporting and illustrating the results of investigations by the Department of Agriculture. The bill provides, however, that

The Secretary may also cause to be disseminated information regarding food, drugs, devices, or cosmetics in cases involving imminent danger to health or gross deception of the consumer.

Clearly, this implies that the secretary may not cause information to be disseminated regarding food, drugs,

devices or cosmetics, except so far as that information is derived from investigations by the Department of Agriculture, unless the danger to the health of the consumer is imminent or the deception of the consumer gross

On the whole, the Copeland food, drugs, devices and cosmetics bill is disappointing in its weakness. It has much in it to be commended, but the medical profession should lend its influence to bring about a rewriting of at least so much of the bill as relates to drugs and prophylactic and therapeutic devices, and possibly of other features. It is important that this be done not only because of the immediate effect of the enactment of the Copeland bill but also because that bill, if enacted, is likely to be adopted as a pattern for state legislation within the next few years, both its weaknesses and its strength. It is hoped, therefore, that through the efforts of the profession and of other agencies interested primarily in the welfare of the consumer, the hands of the Secretary of Agriculture will be strengthened and the health and pocketbooks of the people will be protected by an adequate reenforcement of the pending measure.

Therapeutics

THE THERAPEUTICS OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—ED

THE CAUSAL THERAPY OF CONTACT DERMATITIS

IN COLLABORATION WITH DR. THEODORE CORNBLEET

Eruptions due to chemicals may be the result of the internal administration of drugs, a condition known as medicinal dermatosis, or of direct application of the irritant to the skin, a condition also known as dermatitis venenata and which we shall speak of as contact dermatitis.

DISCOVERY OF THE IRRITANT

A contact dermatitis may be merely the usual reaction to a generally harmful agent, one capable of damaging any skin, or it may be due to an allergen, in the unusual reaction to which the altered reactivity (allergy) of the organism is of prime importance.

While it is usually not difficult to recognize the causal nexus between a generally harmful chemical agent and a resulting dermatitis, it is often hard to discover the allergen responsible for an allergic dermatitis, and obviously this is the most important step in the therapy.

The following method of study of a case is helpful in establishing a diagnosis of contact dermatitis and in detecting the agent responsible for it.

(a) *Distribution of the Lesions*—An eruption on those exposed parts which have the greatest opportunity for contact with an irritant speaks in favor of a contact

dermatitis. Nevertheless, covered parts may be involved, as when there is hypersensitiveness to articles of clothing or to cleansing agents remaining in the clothing, or when transference or dissemination of the irritant occurs. An example of such transference is to be seen in the localization of poison ivy dermatitis on the genitalia. Eruptions produced by internal causes are usually bilateral and often symmetrical.

(b) *The Morphology of the Lesions*—This may help in differentiation between a contact dermatitis and a medicinal dermatosis, in that the former is a simple dermatitis, often of vesicular nature, while the latter takes nearly every possible form except that of simple dermatitis.

(c) *The History*—To find the irritant or irritants responsible for the patient's dermatitis, a clear history of the patient's work, activities and environment is most important. The frequency with which the causal irritant is brought to light depends largely on the diligence and insight of the inquirer. A knowledge of the common irritants used in the various trades and vocations is of material aid. A list of probable or possible skin irritants that the patient is exposed to should be drawn up and the patient tested with these.

(d) *Materials for Reaction*—Almost anything at all may cause a contact dermatitis. Certain substances, however, are more prone than others to produce it. Such agents are most likely to be found among substances having a marked chemical affinity for the skin, thus, keratolytics and detergents and chemicals that have a great affinity for the horny layer of the skin, such as trinitrophenol (picric acid) or paraphenylene diamine (the black dye used for dyeing furs and shoes) or certain metallic salts, as the mercurials, and bodies that are more soluble in fat than in water, such as plant oils and certain alkaloids.

In addition to poison ivy there are many instances of summer dermatitis caused by contact with the leaf or wind borne pollen of other plants, particularly members of the ragweed family. These individuals are apparently sensitive to the lipid fraction of the plant and not to the protein portion. They usually do not have hay fever. In the literature there are several comprehensive lists of common irritants. The safest procedure is to take a careful history and ascertain those things to be suspected which are present in the patient's environment. These materials should first be tested and then others which are known commonly to produce sensitization may be added to them. It takes experience with the method to ferret out the less obvious irritants. But diligence here has its rewards. If the hypersensitivity is monovalent, the discovery of the irritant and its withdrawal will almost always give dramatic results. The dermatitis will improve promptly and spontaneously.

(e) *The Patch Test*—Squares of linen or cotton material about the size of a postage stamp, dipped in or moistened with the test substance in as nearly possible the concentration with which the patient comes in contact with it, are placed on the skin. If the substance is a solid, it should be dissolved in its suitable solvent, water, oil or alcohol. If the test material is an insoluble powder, it is moistened and placed on the skin and covered with the squares of linen. Leaves of plants should be as fresh as possible. A piece of impermeable material, such as cellophane, about four times as large, is put over the test squares and a

"frame" of adhesive plaster anchors all this to the skin. The transparent material is purposely made so much larger to permit differentiation, as nearly as possible, from irritation due to the adhesive plaster. If a few materials are under test, the flexor surface of the arms and forearms may be used. If a large number of substances must be tested, the back is a more convenient site. By arranging the patches in rows, as many as twenty tests may be made here at one time. The patches are left in place for twenty-four hours and then removed, unless the reaction due to their presence is so great and so uncomfortable that they must be removed sooner. Reactions are looked for at the time when the patches are removed and after forty-eight and seventy-two hours from the time of initial contact. Sometimes reactions may be delayed even for several days. Obviously a control patch should always be employed. If the patient is allergic to adhesive plaster, collodion may have to be employed to fasten the patch to the skin.

Interpretation—A positive reaction is denoted by the appearance on the tested area of an eczematous reaction. In other words, the reaction should resemble in appearance the dermatitis clinically present. Care should be taken not to confuse true reactions with pseudo-reactions such as those from adhesive plaster.

False Negative Reaction—If a positive reaction of the type clinically present should appear whenever a certain substance is used in a test, interpretations would indeed be easy. Unfortunately, reactions do not always appear, even if the patient is sensitized to the test substance. A negative reaction may result because the patient is temporarily desensitized by an acute reaction he has just had or because he has remained away from the excitant for some prolonged period of time. The sensitization may be localized, i. e., present in isolated areas, such as on the eyelids or even one eyelid—to eyelash dyes, while other skin areas may be insensitive to this eyelash dye and thus fail to react to it. The V of the neck may be a suitable area for patch tests with substances irritating the face. Sometimes a reaction depends on multiple influences that individually may not suffice to set up a dermatitis. An example of this is seen in the type of dermatitis that may follow exposure to the sun's rays after contact with certain grasses and shrubs.

In some cases, apparently, it is the interplay of heat and sweat, in addition to a specific sensitizing substance, that produces the dermatitis. At times it may be necessary to traumatize the skin somewhat, as by slight multiple scratches on the epidermis, in order to get the proper base for a positive reaction. Failure to appreciate these multiple factors may result in overlooking the cause. The reaction to a specific substance may depend on some other underlying sensitizing state. If this primary condition is removed, it will prevent the test substance from giving the positive reaction it should. An example of this is the dermatitis from leather or other substances when an eczematoid ringworm is present at the same time. When the eczematoid ringworm is cleared up, the individual fails to react to the leather or other substances. With the recurrence of the eczematoid ringworm, the subject again reacts to these excitants and they will then give a positive patch test.

The patch test is not of practical use in chronic lichenified eczema or disseminated neurodermitis, sebor-

rhic dermatitis, urticaria, angioneurotic edema or drug eruptions not of an eczematous character. In recent years dermatologists have come to recognize the complex character of the skin's immunity reactions. It is now known that the skin does not act as a unit throughout its thickness in responding to irritants, but rather through its several components. Each of these has the capacity to react independently with only indirect changes occurring in the rest of the skin. External irritants generally, but not always, affect the outer or epithelial portion, while constitutional or circulating materials in the blood or lymph usually act on the blood vessels, the corium or the subcutaneous layers. An allergic reaction takes place only when an allergen comes in contact with the sensitized tissue. If the deeper parts of the skin are sensitized as in urticaria (q v) the material under test must be injected into the skin or be introduced by scratching away the overlying epithelium, or even ingested to produce the reaction. On the other hand, if the epithelium itself is sensitized, injecting the material under test into the skin or by scratching the epithelium is apt to give a false negative reaction. As, on the other hand, the patch test may give a positive reaction also, with material, e. g., quinine to which the patient is hypersensitive on ingestion, the patch test should be the first one to be performed in the study of allergic dermatoses.

In noneczematous, presumably allergic, dermatoses, this test, if negative, should be followed by endermic and/or ingestion tests (see Urticaria).

False Positive Reaction—A positive patch test does not always mean that the material used to obtain it is the cause of the patient's dermatitis. The dermatitis that the patch test produces should be similar to that present clinically. The material used for the test should be shown to be present as a possibility in the patient's work or surroundings. There must then be an opportunity for contact, as brought out in the history. An individual that becomes sensitive to one substance often develops a sensitivity to others. These may be numerous. The positive patch test therefore may bring to light one of the substances the patient is sensitive to, but not necessarily the one responsible for the clinical condition present. To check up on this, the dermatitis clinically present must be shown to disappear after the material used for the positive patch test is withdrawn from the patient's work or surroundings. It may be necessary for the patient to come in repeated contact with the substance to develop a dermatitis from it. A negative patch test from a single application may in such a case yield a false result. For all these various reasons and others it takes exceeding care and watchfulness to evaluate properly the results of the patch test. It is, of course, necessary that in testing for skin allergy normally harmless concentrations of the test material be employed. Thus, soap will give a positive patch test on the skin of a normal person. For testing, an emulsion of soap must be made that is sufficiently dilute not to irritate normal skin.

PREVENTION OF EXPOSURE TO THE IRRITANT

Elimination of the substance or the substances that give positive skin tests helps in the cure of the skin disease and prevents its recurrence.

In occupational contact dermatitis it is not always necessary for the patient to give up his employment. The use of rubber gloves, for instance, may protect him

sufficiently. The accompanying formula is offered (James, 1934) as a protective film for persons susceptible to paints or varnishes with which they must work. This produces an invisible covering, soluble in water, nonirritating to the normal skin. The only difficulty with the preparation is that its water solubility makes it impossible to keep it on the skin when the skin perspires during hot weather.

In cases of obvious or suspected contact dermatitis in which the irritant cannot be discovered, removing the patient from his home and work may lead to a prompt recovery. If the condition reappears on return to the patient's accustomed surroundings, a painstaking analysis of the materials to which he is exposed and the

patch test may lead to the ultimate discovery of the etiologic agent. Indeed, this "climatotherapeutic test" is useful for the discovery not only of a chemical but also of psychic as well as physical pathogens in a patient's accustomed surroundings.

REMOVAL OF PREDISPOSING CAUSE

Removal of the predisposing cause is chiefly a matter of lessening excessive perspiration and mechanical irritation. Persons who perspire freely are more apt to develop sensitization to external irritants. Excessive sweating is usually an evidence of weakness and it often has a background of overwork and exhaustion. These patients require some form of rest cure, mental, physical or both. If the patient is worn out by lack of sleep, he may need his insomnia (q v) taken care of. Obesity or anemia favor excessive perspiration and the treatment (q v) of these becomes of importance in this connection.

DESENSITIZATION

Desensitization is generally unsuccessful in contact dermatitis for the reason that simple chemical irritants, even when they become allergens, do not produce circulating antibodies. This is in marked contradistinction to such complex antibodies as food proteins and bacteria, which are capable of acting as antigens, producing antibodies. In general antigens are chemically akin to the assimilable foods.

In cases in which an antigen *i. e.*, a substance capable of producing the development of antibodies, is a cause of contact dermatitis, an attempt may be made at desensitization by injecting, for the purpose of immunization, ascending doses of the antigen secured in as pure a form as possible and prepared in the form of sterile highly dilute solution. An example of this method is found in the therapy of ivy poisoning (q v). Desensitization treatment in the case of other types of plant dermatitis has been frequently successful.

SYMPTOMATIC TREATMENT

Whether the cause of a dermatitis can be discovered or not, symptomatic relief is demanded. The details of this are given in connection with the therapy of eczema (q v).

As individuals may be allergic even to the ointment bases employed in treatment, the patch test should be employed to discover such hypersensitiveness when its possibility is suspected.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE.

HOWARD A. CARTER, Secretary

RADIOTHERAPY

(ROENTGEN RAYS, RADIUM)

ARTHUR U. DESJARDINS, M.D.
ROCHESTER, MINN.

BIOLOGIC CONSIDERATIONS

Each variety of cell in the body is specifically sensitive to roentgen rays or radium. Certain varieties of cells are extremely sensitive and are destroyed or injured by small doses, other varieties are resistant and can tolerate large doses with apparent impunity. This does not imply that a given dose of roentgen rays will destroy all cells of a given variety in the irradiated territory, because the sensitiveness of any kind of cell varies somewhat from cell to cell. It would be more accurate to say, therefore, that each variety of cell has a specific range of sensitiveness.

When cells of a given kind are exposed to a certain dose of radiation, some are destroyed, some are injured but regenerate later, and some do not show any deleterious effect. Such variation in the susceptibility of different cells of the same kind is probably due to the metabolic stage of the cells and perhaps to other unknown factors. Whatever the main reason for variation in the radiosensitiveness of different cells of the same variety may be, this does not affect the fundamental law of the specific sensitiveness of different varieties of cells, a law based on innumerable experiments on animals and substantiated by extensive clinical observation.

According to present knowledge, cells may be classified, in the order of the degree of their sensitiveness, as follows:

Lymphoid cells (lymphocytes in the spleen, lymph nodes, intestinal lymph follicles, circulating blood, bone marrow, thymus tonsil, and other structures in which such cells may be present).

Polymorphonuclear leukocytes and eosinophils in the blood or tissues.

Epithelial cells (1) basal epithelium of certain secretory glands, especially the salivary glands, (2) basal epithelium (spermatogonial cells) of the testis and follicular epithelium of the ovary, (3) basal epithelium of the skin, mucous membranes and certain organs, such as the stomach and small intestine, (4) alveolar epithelium of the lungs and epithelium of bile ducts (liver) and (5) epithelium of tubules of the kidneys.

Endothelial cells of blood vessels, pleura and peritoneum.

Connective tissue cells

Muscle cells

Bone cells

Fat cells

Nerve cells

Although the difference in susceptibility between the most sensitive and the least sensitive varieties of cells is considerable, no cell in the body is wholly invulnerable to radiation, all cells, whatever their variety, may be destroyed or injured if exposed to a sufficiently large dose of rays, especially if doses within the therapeutic range are disregarded. It is possible that the apparent difference in radiosensitiveness between certain kinds

of cells, such as between the epithelium of the skin and that lining the bile ducts of the liver, may be chiefly due to the distance between them and the focus of the tube, but the mere factor of distance from the source of radiation (roentgen tube) does not appear sufficient to explain such differences. How, for instance, could the relatively greater sensitiveness of the epithelium of the small than of the large intestine be accounted for? Such difference can be explained only by histophysiologic factors within each structure. Bergonie, Tribondeau and others have shown conclusively that the younger and the more active the cell, from an metabolic point of view, the more susceptible it is to the influence of the rays. Cells that naturally undergo rapid mitotic division and the life cycle of which, therefore, is comparatively short are most radiosensitive. But the relation of the age of the cell to its relative sensitiveness is less important than the specific vulnerability of the different varieties of cells.

LYMPHOID CELLS

The exceptional sensitiveness of lymphocytes was established by the early experiments of Heineke and has since been fully confirmed by Warthin, Krause and Ziegler, Fromme, Jolly, Tsuzuki, Priepborn and many others. When the entire body of an animal is exposed to roentgen rays, the spleen, the mesenteric and other lymph nodes, the intestinal lymph follicles, the blood and bone marrow, the thymus in young animals, and other collections of lymphoid tissue show a more or less marked destruction of lymphocytes, and the degree of such destruction is in proportion to the dose of rays and to the interval between irradiation and death. As the number of intact lymphocytes in the spleen and lymph nodes diminishes, the stroma becomes more prominent, and this feature may become so pronounced that the malpighian corpuscles or lymphoid follicles may largely disappear and be recognizable only by the blood vessels and the concentric arrangement of the corpuscular or follicular stroma. Heineke found destruction of lymphocytes two hours after irradiation, but Warthin, who examined the lymphoid structures sooner after exposure to the rays, found unmistakable evidence of lymphocytic disintegration within fifteen minutes after irradiation.

The destruction of these cells is characterized by disorganization and fragmentation of the nuclear chromatin and by scattering of the fragments of chromatin between the remaining intact cells and in the spaces of the reticular stroma, where the fragments gather into clumps or balls. The extent and the duration of this destructive phase depend on the intensity of irradiation, may continue from one to several days, and are accompanied by a progressive reduction in volume or atrophy of the affected lymphoid structures. Then the clumps or balls of degenerate chromatin are gradually taken up by some of the reticular cells, which assume a phagocytic property and swell as the amount of ingested chromatin debris increases. Such phagocytic disposal of chromatin material from the destroyed cells may continue until the lymphocytes are largely destroyed, but a certain proportion of the cells appear to resist the action of the rays. Some hours later, the phagocytic reticular cells themselves begin to disappear, the chromatin debris ingested by the phagocytes apparently undergoes intracellular digestion, because the number and size of the ingested fragments diminish

steadily. From seven days to three weeks after irradiation, more or less regeneration of lymphoid tissue may be observed.

POLYMORPHONUCLEAR AND EOSINOPHIL LEUKOCYTES

Next to the lymphocytes in sensitiveness to roentgen rays are the polymorphonuclear and eosinophil leukocytes in the circulating blood or in the tissue spaces of different organs. Two or three days after irradiation, degenerative changes in these cells also may occur, but their disintegration is less marked than that of the lymphocytes and is often preceded by a sharp increase in the number of polymorphonuclear cells in the circulation. It is not clear whether such polymorphonuclear leukocytosis is to be regarded as a compensatory or defense reaction or merely as a mobilization of cells to counteract the effect of the rays. In any event the increase in the polymorphonuclear cells, often observed during the first twenty-four hours after irradiation, is but a transient phase and is invariably followed by a varying degree of polynuclear and eosinophilic leukopenia. The extent of cellular destruction, the time at which these cells begin to regenerate, and the rate of regeneration are a measure of the dose of roentgen rays and of the cubic area of body exposed.

THYMUS GLAND

The essential character of the small round cells of the thymus gland has long been the subject of controversy. The extensive investigations of Hammar have led him to conclude that these cells are lymphocytes, and this conclusion is strongly supported by the reaction of these cells to irradiation. Rudberg, Aubertin, and Bordet, Arella, and especially Regaud and Cremieu have shown that the small round cells of the thymus react at the same rate and undergo the same changes as the lymphocytes of the spleen, lymph nodes, intestinal lymph follicles, bone marrow and circulating blood. When the thymic region of a young animal, such as a guinea-pig or a rabbit, is exposed to roentgen rays, the lobules of the thymus exhibit, within twenty-four hours, destruction of small round cells characterized by fragmentation of the chromatin of the nucleus and scattering of the fragments among the remaining intact cells. The degree of cellular disintegration varies with the dose of roentgen rays and may be so extensive as to give the lobules a depopulated appearance, the stroma and blood vessels of the lobules stand out prominently.

As the destruction of small round cells proceeds, some of the reticular cells ingest the scattered fragments of nuclear chromatin and swell in proportion to the amount of the material which they take up. The reticular phagocytes then migrate toward the corpuscles of Hassall and appose themselves to the peripheral cellular layer of the corpuscles. The degenerate chromatin residue from the destroyed lymphocytes then passes from the reticular phagocytes through the successive layers of cells of the corpuscles of Hassall and finally reaches the central clear space of the corpuscle, where the partly digested nuclear debris accumulates as an amorphous mass. As the number of reticular phagocytes accumulating around the periphery of the corpuscles increases, the corpuscles swell to many times their normal size. After all the nuclear debris has passed from the phagocytes to the cells of the corpuscles proper and has reached the central clear space, the corpuscles gradually diminish in size, some recover

their normal dimensions, but many become abnormally small and some disappear completely.

If the gland has been irradiated only once, some of the small round cells are not destroyed, although their mitotic activity is inhibited. After one or two weeks, such cells recover and appear to serve as a nucleus for regeneration, which proceeds more or less rapidly until the number of small round cells in the thymic lobules again approximates the normal. The phase of cellular destruction is accompanied by a corresponding decrease in size and weight of the gland, which recovers its normal dimensions and weight as the cells regenerate. Repeated irradiation, however, may cause destruction of all the lymphocytes, and this is accompanied by marked atrophy of the gland. In this event regeneration does not occur.

EPITHELIUM OF THE SALIVARY GLANDS

Next to the leukocytes in point of radiosensitivity are the basal epithelial cells of the salivary glands. Actually these cells are more sensitive to radiation than the polymorphonuclear and eosinophilic leukocytes, as evidenced by the fact that, whereas microscopically perceptible changes in the last two varieties of cells can seldom be found within the first six hours after exposure to the rays, clinical signs of salivary reaction can usually be observed in from three to six hours after irradiation. These signs consist of swelling, redness and tenderness in the region of the irradiated glands and, when bilateral, may simulate the salivary phase of mumps. If all the glands on both sides have been exposed to the rays, the foregoing clinical signs may be rapidly followed by a decrease in salivary secretion, often leading to dryness of the mouth lasting from a few days to two or more weeks. Microscopically, this reaction of the salivary glands is characterized by mucinous degeneration of the basal epithelium. The amount of mucus in the secretion increases, and the cells may swell to such an extent that the meatus of the excretory ducts becomes occluded, hence the swelling and tenderness of the glands and the dryness of the mouth. After a single irradiation, such salivary reaction is always transient, after a time usually from twenty-four to forty-eight hours the acute phase of the reaction subsides and the clinical signs gradually abate. After repeated irradiation, however, the secretory function of the glands may cease and the dryness of the mouth may persist in some degree for a long time.

It must be clearly understood that these effects can occur only when all the salivary glands on both sides are exposed to the direct action of the rays. Such reaction does not occur when other parts of the body are irradiated, and exposure of the salivary glands on one side causes a reaction on that side only. When the reaction is unilateral, dryness of the mouth is seldom noticed, undoubtedly because the glands on the opposite side furnish sufficient saliva to lubricate the oral mucosa.

EPITHELIUM OF TESTIS AND OVARY

The Testis—It has long been known that the testis is peculiarly sensitive to irradiation. It is not as sensitive, it is true, as some of the leukocytes or as the salivary glands, but, with the exception of these, it is the most sensitive structure in the body. Such susceptibility has been established by numerous experiments on animals as well as by the cessation of seminal function in radiologists and other persons exposed to roentgen rays over a long period of time. The cells of Sertoli

are relatively resistant to irradiation, and this fact tends to support the view that they supply nourishment to the basal layer of true seminal cells, the spermatogonia. The radiosensitivity of the testis is due to susceptibility of the spermatogonial cells, which are affected deleteriously even by a moderate dose of roentgen rays. The spermatocytes of the first and second order, as well as the spermatids and mature spermatozoa, are distinctly less sensitive than the spermatogonia and are affected only by larger doses. Even then much of the cellular degeneration noted is probably secondary to the direct action of the rays on the basal cells.

Microscopic examination of the seminal tubules some days after irradiation may disclose vacuolization and degeneration of some or all of the spermatogonia, depending on the dose of roentgen rays to which the organ has been exposed. After a sufficiently large dose, the degeneration of the spermatogonia proceeds to complete disintegration. This is accompanied by failure of the cells to evolve into spermatocytes and then to mature spermatozoa, and the final result may be a permanent azoospermia. After a dose insufficient to cause permanent azoospermia, a certain proportion of the spermatogonia may be able to survive and serve as a nucleus for histologic regeneration and functional restoration. Repeated large doses at comparatively short intervals are almost certain to induce permanent roentgen castration. The interstitial tissue, on the other hand, is much more resistant and is not perceptibly influenced by ordinary therapeutic irradiation. Needless to say, however, even the interstitial tissue could be irreparably injured by excessive irradiation beyond the therapeutic range.

The Ovary—The radiosensitivity of the ovary is essentially the same as that of the testis, and the cells to which the specific susceptibility of the gland is due are the ova and the epithelial cells of the follicles. The sensitivity of different follicles varies according to the stage of their development, and the effect of irradiation may be the disintegration and disappearance of a certain proportion of the follicles or complete and permanent destruction of every follicular structure, depending on the dose of rays to which the ovary has been exposed or on the number of times a given dose has been repeated. Moreover, the steps in the reaction of the follicles are analogous to those of spontaneous physiologic atresia.

The follicular reaction appears from three to six hours after exposure and is particularly marked in the mature follicles. In the primary follicles the rays act on the ovum sooner than on the follicular epithelium and such action is featured by pyknosis of the germinal vesicle, condensation of the protoplasm and finally chromatolysis and fragmentation of the cell. The cellular fragments then undergo phagocytosis by the follicular epithelial cells, which themselves degenerate as soon as the phagocytic disposal of the fragmented ova is complete. These different steps require three or four days, but, since all the follicles do not begin to react at the same time, a week or more may elapse before all the affected follicles have disappeared. A single irradiation within the range of therapeutic doses may not destroy all the follicles.

The same cycle of changes occurs in the more mature follicles with several layers of epithelium, but in these the follicular epithelium is much more sensitive and its cells undergo rapid autolysis. Moreover, the connective

tissue cells of the theca interna degenerate as rapidly as the epithelial cells. In the still more mature follicles, in which the ovum is large and separated from the follicular epithelium by a membrana pellucida, the epithelial cells first penetrate this membrane by diapedesis, dispose of the degenerate ova by phagocytosis, and in turn degenerate and disappear. Such migration of the epithelial cells begins about the third day, and the degenerative process continues for two or three weeks. Usually all such follicles are destroyed by irradiation, but on account of the large size of the ova the autolytic process may require considerable time.

In fully developed follicles the epithelial cells are still more radiosensitive, most of the parietal epithelium of the follicular cavity being destroyed by irradiation, whereas the epithelial cells which surround the ovum are slightly less sensitive. Sometimes irradiation may be followed by an accelerated maturation of the ovum, followed by degeneration. Thus the radiosensitivity of the ovarian follicles increases in proportion to their development. Follicles in process of maturation are readily destroyed by exposure to roentgen rays, but a certain proportion of the primordial follicles may escape if the dose has been small.

The interstitial cells of the ovary do not appear to be influenced directly by the rays but gradually and slowly disappear, probably because the destruction and disappearance of the follicles prevents the interstitial cells from being renewed. The follicular degeneration that follows irradiation is accompanied by a corresponding atrophy and reduction in weight of the ovary.

EPITHELIUM OF THE SKIN AND MUCOUS MEMBRANES

The Skin—The skin can tolerate with impunity a considerable single dose of roentgen rays, but when its limit of tolerance is exceeded it may undergo a series of reactive changes.

Early Effects In the case of the scalp the first clinical manifestation of excessive irradiation from a physiologic but not from a therapeutic standpoint, is a readiness of the hair to fall out in the exposed territory. The hair can be plucked with unusual ease or may fall spontaneously. Such epilation occurs two or three weeks after irradiation and continues for a short time. After relatively small doses epilation is only temporary, but after sufficiently large doses the alopecia is permanent. In the case of the skin of the body as a whole (other than that of the scalp), following a single dose of roentgen rays or radium, erythema may occur without epilation, or epilation and erythema may occur more or less simultaneously. After a still larger dose not only does epilation occur but varying degrees of reactive inflammation of the skin may take place. Dermatitis may appear as a mere erythema lasting a few days followed by slight pigmentation corresponding to the exposed area, as more pronounced, bright red erythema, with a sensation of heat followed by the formation of vesicles and later by itching, exfoliation of the epidermis and deep pigmentation, or, in extreme cases, as intense, painful erythema, with or without fever, and followed by more or less extensive ulceration of the entire thickness of the skin. The mild grade of radiodermatitis usually does not leave permanent marks beyond slight atrophy of the irradiated area of skin, provided the inflammatory reaction resulted from a single exposure and was not preceded or followed by

other exposures. If such a reaction should appear after the same area of skin has been exposed several times, it is likely to be followed, from one to three years later by telangiectasis. Needless to say, the sudoriferous and sebaceous glands of the irradiated skin also undergo degenerative changes.

Radiodermatitis accompanied by the formation of vesicles is soon followed by more extensive desquamation or by the actual formation of small rounded or larger, irregular cutaneous scars. When radiodermatitis is sufficiently severe to lead to ulceration, the ulcers are noted for their slow healing. This is due partly to the peculiar character of the cellular injury produced by irradiation and partly to the secondary infection which so commonly complicates the ulceration. The severe grades of radiodermatitis generally result from inexperience, from a miscalculation of some of the dosage factors, or from the accidental omission of a certain filter with a dose based on the use of filtered rays.

The rays act on the epithelium of the hair follicles. This explains the loosening or falling of the hair. As is well known, the elective sensitiveness of the hair follicles is made use of in the treatment of skin diseases such as ringworm, in which the dose of roentgen rays is adjusted so as to cause temporary epilation. The success of the treatment rests on the ability of the radiologist to regulate the dose within narrow limits, any uncertainty in this respect may result in permanent alopecia or worse. When the dose is sufficient to cause distinct erythema, the microscopic changes include an irritative disturbance of the basal layer of cells accompanied by hyperemia and edema, and later by degeneration and desquamation of the epidermis. After still larger single doses, these cellular and circulatory alterations may be quite marked and may extend to all the layers of the skin.

The rays also act on the endothelium of the blood vessels, causing these cells, and sometimes the entire intima, to swell and to undergo hyperplasia and later connective tissue proliferation, which may lead to reduction in the caliber or actual obliteration of the vessels. This serves to explain in some measure the slow healing of radiodermatitic ulcers, an explanation further substantiated by the fact that a dose several times greater may be given to a very small area of skin (from 1.5 to 2 cm. or less) without causing ulceration.

Late Effects Besides the foregoing acute effects of irradiation and their sequelae, there exist two varieties of late effects. One variety is featured by late necrosis in a region of the skin subjected, several months or even several years before, to repeated irradiation to the point of inducing early lesions, such as have been described. Such necrosis commonly follows slight trauma but may occur without any apparent, immediate cause. It begins with redness, pain, swelling and a sensation of heat, and a short time later a progressive ulceration similar to that which typifies early radiodermatitis of the third degree. It is probable that the chief determining cause of such late ulceration is infection of the connective tissue, the natural resistance of which has diminished as a result of obliterative changes in the blood vessels and other chronic changes in the connective tissue itself.

The second variety of late radiodermatitis is encountered in cases of physicians or others who may have been exposed to roentgen rays or radium at frequent intervals for a long period of time. It affects usually the hands and sometimes the face. The lesions appear

only after years of daily exposure and consist of a thickening of the skin, with redness and sensitiveness, and often also of a dryness and brittleness of the nails. In fact, changes in the nails often precede other evidences of injury. The skin becomes harsh and tends to crack easily, and areas of keratosis develop, which later may undergo epitheliomatous transformation. Many of the pioneers in roentgenology have had the misfortune to pay for their ignorance of the danger or for their carelessness, with the loss of fingers, hands or entire extremities, and a number have lost their lives.

MUCOUS MEMBRANES

The sensitiveness of the epithelium of mucous membranes is much the same as that of the skin. Excessive single irradiation causes first anesthesia, then dryness, redness from hyperemia, and edema. Depending on the doses, these clinical manifestations may abate and disappear or may be followed by ulceration. Excessive repeated exposure causes a hyperplastic thickening of the epithelium, and this may be followed by necrosis.

SPECIALIZED MUCOUS MEMBRANES

The Stomach and Intestine—The radiosensitiveness of specialized mucous membranes, such as the mucosa of the stomach and intestine, varies with each structure. Irradiation of the stomach causes temporary reduction in the secretion of gastric juice, and this affects the production of hydrochloric acid and pepsin. If the stomach is exposed repeatedly at relatively short intervals, the gastric acidity and pepsin fall lower and lower. Such an effect may continue for several weeks or several months. If the exposures should be repeated indefinitely it is conceivable, if not indeed probable, that the secretory activity of the gastric mucosa would be completely and permanently destroyed. The susceptibility of the intestine varies in its different parts. The mucosa of the colon is relatively insensitive to the action of the rays, at least, it is much less sensitive than that of the small intestine. The most radiosensitive portion of the mucosa of the digestive tract is that of the duodenum and jejunum, in which irritative reactions may occur after doses insufficient to cause any disturbance in the overlying skin. When the upper half of the abdomen is exposed to a therapeutic dose of roentgen rays, anorexia, nausea and vomiting often follow within a few hours, and diarrhea may appear several days later. Exposure to excessive doses, such as have been employed in many experiments on animals, causes mucinous degeneration of the intestinal epithelium, hyperemia, and edema of the mucosa and submucosa, and such changes may be sufficiently marked to be followed by desquamation of the epithelium. According to the severity of the reaction, the epithelium may regenerate or the breach in the mucosa may be repaired by connective tissue.

EPITHELIUM OF THE LUNGS AND LIVER

The lungs are comparatively resistant to the action of roentgen rays, but if the overlying skin is exposed to a grossly excessive dose, especially if the thoracic wall is thin and if such a dose is repeated several times, reactive pneumonitis is likely to follow. This may subside spontaneously without any after-effects or may be followed by fibrous repair and more or less impairment of respiratory function.

As a whole, the liver is still less radiosensitive than the lungs. Most of the pathologic changes in the liver

that have been found after experimental irradiation of animals have not been direct effects of the rays but an indirect effect of cellular changes in other more sensitive structures. The epithelium of the biliary ducts, however, appears to be slightly more sensitive than the hepatic cells themselves, but it is not clear whether the alterations that have been observed resulted from the direct action of the rays or whether they also were secondary to the circulation of toxic products of cellular degeneration in remote organs.

EPITHELIUM OF THE KIDNEYS

The kidneys can hardly be regarded as radiosensitive organs, as far as therapeutic doses of roentgen rays are concerned. Yet excessive irradiation may cause slight, moderate or severe nephritis. The cells first affected are the epithelial cells of the convoluted tubules. Nephritis should never occur in radiotherapy as applied to human beings. Its appearance must immediately suggest either gross overdosage or excessive elimination of toxic products of cellular degeneration in other more sensitive structures or tissues. Certain animal experiments have shown that, if therapeutic doses are disregarded and if the kidney is exposed to several times an ordinary therapeutic dose, the organ may undergo reactive inflammation leading to chronic nephritis, with increase in blood pressure and the usual reverberations associated with that condition. Such an effect merely shows that the kidney, like all other organs and tissues, is not wholly insensitive to radiation but may be injured more or less severely and permanently if its limit of tolerance is exceeded. But it must not be inferred that ordinary therapeutic irradiation of the kidneys is dangerous.

ENDOTHELIUM

The radiosensitiveness of the endothelium of the blood vessels, pleura and peritoneum is approximately the same as that of the skin. In other words, a dose of roentgen rays insufficient to irritate the skin is not likely to have an appreciable effect on the endothelial cells. When the tolerance of the skin is exceeded, however, the endothelium is likely to suffer temporary or permanent injury. The effect of a grossly excessive dose on the blood vessels is swelling of the endothelial cells, some or all of which in the irradiated area may degenerate and desquamate into the lumen of the vessel. The media also may swell more or less. As the acute phase subsides, the destroyed endothelial cells are replaced by hyperplasia of adjacent cells which may have suffered less, and the intima or the entire vessel wall thickens by hyperplasia of connective tissue. The result is a slow narrowing of the lumen of the affected vessels, which may or may not proceed to the point of complete obliteration. Similar changes occur in the pleura and peritoneum. Naturally the effect of excessive irradiation may not be confined to these structures but may extend to the underlying parenchyma of the lung or to the wall of the intestine or other tissues underlying the peritoneal endothelium. The endothelial degeneration is usually accompanied by hyperemia and serous exudation and terminates by chronic adhesive pleuritis or peritonitis. If the dose of roentgen rays has been sufficiently intense, the injury to the underlying tissues may outweigh the effect on the endothelium and may have serious consequences. It is important, therefore, to keep the dose within safe therapeutic limits.

CONNECTIVE TISSUE CELLS

Young, freshly formed connective tissue cells are more radiosensitive, and mature connective tissue cells are less sensitive to irradiation, than the epithelium of the skin. Young connective tissue, in a healing traumatic or surgical wound, for example, is peculiarly sensitive to roentgen rays and, even after moderate therapeutic exposure, becomes more porous and more brittle. Moreover, moderate therapeutic irradiation of such connective tissue diminishes its formation or tends to hasten the granulation process. This effect appears to be due more to the action of the rays on the leukocytes infiltrating the area and the connective tissue changes, therefore, are partly secondary or indirect, but a direct effect on the connective tissue cells also occurs. This is evidenced by the influence of roentgen rays on keloids, for which radiotherapy is the most effective treatment. Mature connective tissue cells, on the other hand, are distinctly more resistant than the epithelium of the skin, but, if a dose beyond the limit of tolerance of the skin is given, the connective tissue cells in the exposed territory may also be affected. Some may be destroyed and fresh connective tissue may be formed. This probably has given rise to the assumption that the formation of such tissue may be stimulated by irradiation. Such stimulation is never a direct result of exposure to the rays but is an indirect result and always implies an antecedent destruction of cells of the same or of some other variety.

MUSCLE CELLS

The cells that typify voluntary or involuntary muscles also may be injured or destroyed by exposure to roentgen rays beyond therapeutic limits, but this involves still greater injury or destruction of the overlying tissues or the convergence on the muscle of several beams of rays directed toward it through as many separate fields. Muscle cells are comparatively resistant to the action of the rays and, if not excessive, therapeutic doses should not have a deleterious influence on them. Pathologic changes, such as fatty degeneration, sometimes observed in muscle cells after exposure to roentgen rays, usually result from the circulation of toxic products of cellular degeneration in other more sensitive tissues or structures.

BONE CELLS

Bone has long been thought to be impervious to the influence of roentgen rays. It possesses a relatively high degree of resistance, it is true, but sufficiently intense irradiation, in either single or repeated exposures, may cause the bone cells to degenerate. The degree of effect varies with the dose and with the age of the irradiated animal or person. In early life the growth of bone can readily be retarded or permanently stopped by therapeutic irradiation especially if the exposures are repeated. Adult bone, however, is able to tolerate rather large doses of roentgen rays without any apparent effect. Irradiation beyond the therapeutic range of dosage may cause the bone cells to degenerate and the bone to become devitalized. In the absence of infection devitalized bone is slowly replaced by ingrowing new bone especially if the affected bone is used for weight bearing. When on the contrary, mechanical function is prevented by fracture or otherwise, the devitalized bone separates as a sequestrum,

which is slowly absorbed. Secondary infection of bone devitalized by irradiation leads to sequestrum formation, regardless of function.

NERVE CELLS

As far as experimental evidence shows, the neurons of the central nervous system possess the highest degree of resistance to roentgen rays. The brain and spinal cord can tolerate maximal therapeutic doses and even more with apparent impunity. But this must not be taken to mean that the specific cells of the nervous system are entirely invulnerable to the rays. Nevertheless, in many experiments on animals, in which doses several times greater than those used in the treatment of human beings were administered to the brain or spinal cord, the nerve cells did not show any perceptible evidence of a direct action of the rays. Such cellular changes as have been found after irradiation have appeared to be secondary to the action of the rays on the cerebral vessels, the endothelial lining of which is more sensitive than the nerve cells themselves.

STIMULATING EFFECT OF IRRADIATION

For years the legend that roentgen rays, under certain conditions of dosage, may increase the growth and metabolism of cells has gained wide circulation. This notion has arisen from the attempt to apply to roentgen and radium rays the so-called Arndt-Schulz law, according to which small doses stimulate, and large doses depress, cellular metabolism. Based on pharmacologic grounds, this doctrine has not been generally accepted, even by the pharmacologists. The attempt to apply it to the action of roentgen rays is unwarranted, because the experimental evidence on which it is based is extremely meager and apparently invalid. That a measure of acceleration in cellular metabolism may occur under certain conditions has been shown repeatedly both in animals and in plants, but such unusual acceleration is but a transient phase of the reaction to irradiation and is invariably followed by more or less pronounced inhibition of function and cellular degeneration.

Another factor in the propagation of this notion of a stimulating action of the rays has been the commonly observed regression of pathologic lesions after exposure to small doses of roentgen rays. Such regression is best explained by the exceptional radiosensitiveness of cells, as will be shown in the third section of this chapter.

As the result of a primary degenerative effect on certain cells, a secondary and indirect stimulation may sometimes be observed. Such is the increase in connective tissue cells in certain tissues and organs after repeated irradiation, the connective tissue is laid down to replace other cells which the rays have caused to undergo degeneration. Any primary or direct acceleration of cellular metabolism must be regarded as an effort of the cell to counteract or compensate for the noxious influence of the rays, in other words, it is purely a defense reaction.

Continued acceleration of metabolism cannot be produced by exposure to any dose of roentgen rays or radium, which always cause degenerative changes or have no effect whatever. Repeated irradiation of certain tissues, such as the skin, over a long period of time may cause hyperplasia of the epithelium, and this in turn may lead to malignant transformation. This is

not stimulation in the sense here employed, but the alteration of a normal to an aberrant function due to chronic irritation

CLINICAL RADIOTHERAPY

RADIUM OR ROENTGEN RAYS

Too much stress on radium or on roentgen rays has been laid by certain writers who, not possessing both agents, have naturally tended to stress the agent which they happened to possess. The question is not one of radium versus roentgen rays but of the relative advantages and disadvantages of each agent. A thorough knowledge of these advantages and disadvantages should govern the indications and contraindications for each. In certain conditions, or in certain phases of the same condition, radium may be preferable to roentgen rays, and vice versa. Sometimes the two agents may be combined to advantage, and some conditions may be treated as effectively with one agent as with the other, the relative advantage then being a matter of time, availability, convenience and cost. Technical considerations may also enter into the decision to use radium or roentgen rays, or both, in a given case.

In a general way radium is preferable when the lesion is well defined, of limited size, and situated at the surface or readily accessible from the surface. Thus a nevus or small keloid may preferably be treated with radium, but it may also be treated with roentgen rays. A large keloid is best treated with roentgen rays, unless a large quantity of radium is available, even then the relative cost makes treatment with roentgen rays preferable. Whenever the lesions cover an area of considerable size, roentgen rays usually are to be preferred, because the affected territory can thus be irradiated more uniformly in less time and at smaller cost. In connection with tumors, sometimes either agent may be used with equal effectiveness, and sometimes the best results are obtained by suitably combining them. In carcinoma of the uterine cervix, for example, the indications for radium treatment are almost ideal, because the cervico-uterine canal permits the introduction of radium into the very center of the malignant process. Moreover, the vaginal cavity makes it possible to apply additional radium to the cervix itself. But the best results are obtained when, besides direct local irradiation with radium, supplementary irradiation with roentgen rays or with a large quantity of radium is directed to the pelvic structures from without.

In the case of a sarcoma of the shoulder, a carcinoma of the lung, a lymphoblastomatous process of the mediastinum or abdomen, an embryoma of the kidney, or a tumor of the testis with metastasis to the para-aortic (retroperitoneal) lymph nodes, adequate irradiation can usually best be done with roentgen rays. Such lesions can be treated with radium only in a few institutions where a quantity of radium large enough to permit external irradiation under satisfactory conditions is available.

In carcinoma of the breast, radium or radon can sometimes be implanted throughout and around the primary growth, but this and the tributary lymphatics should also be irradiated from the outside, either with roentgen rays or with radium. The aim throughout should be to concentrate in and around any malignant process the largest total dose of rays compatible with the integrity of the surrounding normal tissues.

INTERNAL ADMINISTRATION OF RADIUM

Some years ago the internal use of solutions of radium for arthritis, gout, high blood pressure, neuralgia, leukemia and other conditions was advocated and was practiced to a considerable extent, but the results have not been satisfactory and the method has largely been given up, except by the charlatans.

Much has been made also of the therapeutic virtues of the water of certain springs, and claims have often been based on the radioactive content of such water. The quantity of radioactive energy present in the water of most natural springs is quite small—too small to have any perceptible therapeutic effect. Any virtues such water may possess are almost certainly not due to radioactivity. It is probable that the benefit of a stay at such springs results mainly from the regimen in general and not from any radioactive effect of the water.

INFLAMMATORY DISEASES

General Considerations—So much has been written about radiotherapy for malignant tumors that many physicians are not aware that many forms of acute or chronic inflammation also are amenable to treatment with roentgen rays. Other physicians who, to some extent, may be familiar with the therapeutic possibilities of roentgen irradiation for various inflammatory processes hesitate nevertheless to make use of the method because they fear either the deleterious effects of excessive irradiation on the skin, not infrequently encountered after the treatment of tumors with maximal doses, or the systemic reaction with which such treatment is often associated. As far as inflammatory lesions are concerned, provided the treatment is administered by a radiologist who has had substantial experience with the treatment of inflammations, such fears are unfounded.

For the benefit of those who may not be familiar with the subject, it must be emphasized that radiotherapy for inflammatory conditions is an entirely separate field from the treatment of malignant neoplasms. In the latter the aim must be to deliver to every part of a tumor the largest total dose of rays compatible with the integrity of the overlying and surrounding tissues, while, in the former, comparatively small or moderate doses are employed. Large doses that might jeopardize the integrity of the skin are not only unnecessary but should be carefully avoided as less effective and sometimes as actually dangerous. The risk of complicating the inflammation already present by inducing inflammatory reaction to an excessive dose of rays may lead to spread rather than resolution of the primary inflammation.

Acute—Many forms of acute inflammation yield quite rapidly to a single, small dose of rays. In some cases in order to cause complete resolution of the pathologic process, it may be advisable to repeat irradiation after an interval of from six to ten days. By a small dose of rays is meant a dose representing less than one-half the tolerance dose of the skin, a dose as small as one-fourth the so-called erythema dose is often sufficient, but the exact dose must vary somewhat according to the character of the lesion in each case. A significant point is that, other things being equal, the more acute the lesion, the smaller the dose of rays required. Another significant point is that the results are most striking and prompt when the lesions are irradiated early, during the stage of leukocytic infiltration and before suppuration has set in. Irradiation later

may still be useful, in that suppuration is favored and the process may thus be shortened to an extent which varies with the stage of the lesion at the time of irradiation. Another advantage of the method, especially for early lesions, is prompt relief from pain, although sometimes relief may be preceded by actual increase in pain for a brief period.

As examples of inflammatory lesions notably amenable to roentgen irradiation may be mentioned furuncle, carbuncle, acute simple adenitis, acute parotitis complicating operations on the colon and other abdominal structures, abscess and cellulitis of soft tissues, onychia and paronychia, mastitis, sinusitis and mastoiditis in selected cases, and delayed resolution of lobar pneumonia.

The favorable influence of irradiation on furuncle and carbuncle, especially when treated early, has been demonstrated by Coyle, Dunham, Ross, Richards, Lewis and many others. Prompt and marked benefit is derived in a large proportion of cases. Indeed, when treated early, relief from pain within a few hours and rapid resolution are the rule. When treated late, suppuration tends to be hastened, and surgical drainage may have to be instituted earlier than would be the case if the lesion had not been irradiated. As already mentioned, the treatment is most effective during the early stage when other methods of treatment are least effective, it is painless and inexpensive and does not interfere with the patient's activities, it often relieves pain in a short time, makes hot or other dressings unnecessary or shortens the period during which they must be applied, it often avoids an operation, and it usually yields a better cosmetic result. The dose of rays is so small that reaction of the skin or of the gastro-intestinal tract does not occur. Consequently, the treatment may be given to weak and febrile patients without danger.

Ocular Lesions—Certain inflammatory conditions of the eye can be treated effectively with radium or with roentgen rays. In dealing with such lesions the advantage usually lies in roentgen irradiation, because the small doses required can be given in a much shorter time and without the difficulty and discomfort incidental to the application of radium to a mobile and sometimes acutely inflamed structure. The dose of rays must never exceed 80 per cent of an erythema dose, otherwise, early conjunctivitis or late degeneration of the crystalline lens may follow. This is especially prone to occur in children.

Parotitis, Acute—Certain operations, notably on the colon, are complicated by acute parotitis, and a high mortality rate is attached to this complication. In such cases early exposure of the parotid regions to a small dose of roentgen rays or radium has been found effective in controlling and in arresting this variety of inflammation, and the mortality rate has thus been notably reduced. When the patient's condition allows him to be moved to a nearby treatment room, irradiation with roentgen rays is simpler and requires less time than that with radium. But if the patient's condition is such that any movement is to be avoided, treatment with radium is preferable because it can be administered without disturbing the patient.

Not all acute inflammatory lesions respond favorably, but a large percentage may be counted on to do so. Moreover, if the pathologic process is not favorably influenced, its evolution is not perceptibly altered.

(To be continued)

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

BACILLUS ACIDOPHILUS CULTURE (B A CULTURE) OMITTED FROM N N R

Bacillus Acidophilus Culture (B A Culture), manufactured by the B B Culture Laboratory, Inc., was accepted for inclusion in New and Nonofficial Remedies in 1926. The product is a concentrated culture or suspension of *B. acidophilus* stated to contain not less than 100 million organisms (*Bacillus acidophilus*) per cubic centimeter at the date of issue.

At the expiration of the last three year period of acceptance in 1932, the product was reaccepted for one year only, on account of the fact that the Council is reconsidering the whole status of bacillus acidophilus therapy. At that time certain revisions of the firm's label and circular were required. For the Council's reconsideration in 1934, the firm submitted proof of label and circular revised to meet these objections. These revisions were found acceptable except for the use of the initials "B A." In its reconsideration, the Council found two objections to the continued acceptance of this concentrated culture or suspension of *B. acidophilus*.

The first, a general objection, is that there appear to be available no published reports satisfactorily proving that broth cultures, whey cultures and concentrates of *B. acidophilus* are therapeutically useful. One of the Council's consultants, who is thoroughly familiar with this field, has written in answer to a question concerning the therapeutic value of this type of product: "I know of no references good or bad on clinical studies dealing with the therapeutic value of acidophilus cultures and concentrates." The facts are that all thorough clinical studies have been made with *B. acidophilus* milk and the information derived from them has been transferred to the cultures and concentrates. In its submitted advertising the B B Culture Laboratory, Inc., claims: "In the conditions mentioned above, where the implantation of *B. acidophilus* is indicated, *Bacillus Acidophilus* Culture (B A Culture) will be found effective, convenient and economical." The Council must regard this claim as being unwarranted until the firm submits convincing evidence to support it.

The second objection relates to the instability of these cultures and concentrates. It has been known for a long time that *Bacillus acidophilus* loses viability rapidly in these preparations. Bacteriologic analyses made for the Council by a competent investigator in this field show this clearly for several preparations of this sort, among which were two samples of this *Bacillus Acidophilus* culture. The results of these tests were as follows:

Two samples of the *Bacillus Acidophilus* Culture of the B B Culture Laboratory, Inc. were obtained in New York at 8 p. m. on May 28, 1934. The date of manufacture was stated on the label to be May 25, 1934. The expiration date was July 20, 1934. Counts of *Bacillus acidophilus* were as follows:

| | No. of Viable <i>B. Acidophilus</i> Organisms | |
|---------------------------|---|--------------------------------|
| | At Date of Purchase, 5/29/34 | At Date of Expiration, 7/20/34 |
| Medium | | |
| Tomato juice agar pH 6.6 | | |
| (a) in 10% carbon dioxide | 655 million | 1 million |
| (b) in air | 670 million | 1 million |
| Casew digest agar pH 7.1 | | |
| (a) in 10% carbon dioxide | 656 million | 1 million |
| (b) in air | 659 million | 1 million |

These counts show that the product deteriorated greatly in storage at 10-18 C during fifty-two days which was four days less than the eight weeks expiration period. The firm's label guarantees "not less than 100 million viable *B. acidophilus* at the expiration date." This claim is obviously unwarranted in view of these observations.

The general article Lactic Acid-Producing Organisms and Preparations in N N R. contains the statement (New and Nonofficial Remedies 1935, p 263) that the expiration date for B acidophilus milk preparations will "usually be one week, and probably less than two weeks, after the date of manufacture" Since some of the milk preparations appear to be quite stable, the Council has extended their expiration date to three weeks during a trial period The cultures and concentrates should have expiration periods shorter than those of the milk products Certainly the period of eight weeks used by this firm was much too long It is doubtful whether these cultures and concentrates can be satisfactorily marketed within the brief expiration period, probably less than one week, during which the viability of B acidophilus organisms in them can be maintained.

The type of culture in this preparation was found to be an intermediate rough form It is not certain that this preparation represents the true intestinal type of B acidophilus suitable for implantation.

The Council voted to omit Bacillus Acidophilus Culture (B A Culture) of the B B Culture Laboratory, Inc, from New and Nonofficial Remedies because there is insufficient evidence supporting claims for its therapeutic value and because, like other cultures and concentrates, it is subject to great deterioration

The foregoing statement of the Council's consideration was transmitted to the B B Culture Laboratory, Inc. The firm replied, raising objections and asking for postponement of the publication of the Council's statement Publication was withheld pending the results of a reinvestigation of some of the problems involved

The firm objected to the classification of its product as a culture concentrate. Since the product has always been described in New and Nonofficial Remedies as a "pure aqueous suspension of Bacillus acidophilus," and since the firm has never objected to this description, there is little basis for such objection The firm now states that "This culture is a natural 24-hour growth in a medium developed by us and is not a concentrate." As there are more serious objections to the product, the Council's only concern here is to make sure that the preparation is accurately described in this statement The firm has indicated that the product is a culture which has not been concentrated by artificial means

The firm objected to the requirement that the initials "B A" be removed from the name, but expressed willingness to consider any specific objections to the use of these letters The letters are now in conflict with the Council's rule 8 and would have to be deleted if the product should be reaccepted.

In answer to the objection that there is no evidence for the therapeutic value of this product, the firm submitted three references to published papers and stated "The best evidence of success following this treatment is after all the testimony of physicians which comes to us Unfortunately, perhaps, this evidence was not given us for publication." The Council has considered the papers of Coleman, Gompertz and Vorhaus, and Albee, which were referred to by the firm

Coleman (THE JOURNAL, Aug 4, 1917, p 329) does not claim that B acidophilus therapy had any specific value in typhoid fever, but that it did reduce diarrhea and tympanites All the patients treated by him received a high calory diet and were kept in good nutritional condition He emphasizes, as do others, the importance of the general nutritional state of these patients There is little or nothing in his reports to show that patients treated with the B acidophilus culture prepared by Torrey were better off than those given lactose and good care without the culture. It may be concluded from his paper, however, that diarrhea and tympanites were probably reduced by the B acidophilus therapy The organisms were administered in cultures prepared especially by Dr Torrey and the patients were not treated with a commercial preparation These results cannot be transferred to the use of 'B A Culture' without confirmation by actual test

The article by Gompertz and Vorhaus (THE JOURNAL, Jan. 13 1923 p 90) gives no information on the type and source of the culture used Implantation of B acidophilus was appar-

ently obtained by these investigators, though the bacteriologic studies, limited largely to examination of stained specimens, are deficient

The Council does not deny that implantation of B acidophilus can be secured by the oral administration of suitable broth cultures It is, however, not impressed with the work done thus far in the therapeutic use of broth cultures, suspensions or concentrates, it believes that convincing evidence is needed to show that the commercial preparations of this type are therapeutically effective.

The paper by Albee (*Am J Surg* 23 70 [Jan] 1934) does not give any analyzable or convincing evidence. The title of the paper is "Myofascitis," a term coined by Dr Albee to designate vague muscle and joint pains, lumbosacral troubles and a number of ill defined conditions He used manipulation, massage and colonic irrigation along with cultures of B acidophilus in the treatment of his patients The Council recognizes the fact that the element of psychotherapy in the treatment of patients of this type together with the effect of general dietary and hygienic regulation may have great influence on the results obtained. There are no bacteriologic data in Dr Albee's paper

In view of the firm's reference to the "testimony of physicians not given us for publication," the Council again points out that the usual testimonial letter of a physician does not constitute scientific evidence The Council could not regard as convincing letters of that sort which may be in the firm's file

At present the Council knows no reason to change its opinion (a) that there is no satisfactory evidence that culture-preparations of this type are therapeutically effective and (b) that there is no satisfactory evidence to support the claim advanced by the firm in the sentence "In the conditions mentioned above, where the implantation of B acidophilus is indicated, Bacillus Acidophilus (B A Culture) will be found effective"

The firm was requested in January 1935 to submit evidence in the form of reports of carefully controlled studies of (1) the implantation of B acidophilus in the intestine of man by the administration of "B A Culture" and (2) therapeutic effects from the use of this culture or other culture preparations, exclusive of B acidophilus milk¹

The firm criticized the bacteriologic report reproduced in the Council's statement previously transmitted to the firm and presented the results of routine analyses made by Dr Kopeloff and by the firm as evidence that the Council's statement was not accurate. After correspondence with the firm there was received a supply of the firm's own special medium. Samples of the firm's product were purchased on the New York market and arrangements were made for a bacteriologic examination to be made by a competent worker under the supervision of the Council's referee Every care was taken to follow the directions specified by the firm in the plate count procedures, the care and handling of specimens and in all other details. The results of this analysis are as follows

I Tests of viability of B acidophilus in the B A Culture under conditions recommended by the firm to the user Bottles opened were returned to the refrigerator at 50 F after each sample was withdrawn. The firm advised in its letter of Jan 26 1935 Tests of viability after opening bottles should not be made more than ten days after bottle is opened

Two samples were examined in this way under the referee's supervision The results according to two methods were as follows

Sample 1 Produced Jan 23 1935 Expires March 11 1935
Purchased Feb 4 1935 Examination begun Feb 8 1935
Bacillus acidophilus counts (maximum of any dilution)

| Days After Opening Bottle | B B Labora- tory Medium | Tomato Agar Under Carbon Dioxide |
|------------------------------|----------------------------|--|
| 0 | 540 000 000 | 600 000 000 |
| 2 | 150 000 000 | 370 000 000 |
| 4 | 40 000 000 | 30 000 000 |
| 6 | 10 000 000 | 9 000 000 |
| 8 | 20 000 000 | 10 000 000 |
| 10 | 7,000 000 | 3 000 000 |

This shows that viability of the organisms was lost rapidly The product was below the minimal Council standard six days after the bottle had been opened

1 At the time this addition to the original statement was formulated the firm had not furnished any new evidence on these points

Sample 2 "Produced Feb 4 1935 Expires March 20 1935"
Purchased Feb 6 1935 Examination begun Feb 8 1935
Bacillus acidophilus counts (maximum of any dilution)

| Days After Opening Bottle | B B Labora- tory Medium | Tomato Agar Under Carbon Dioxide |
|------------------------------|----------------------------|--|
| 0 | 770 000 000 | 720 000 000 |
| 2 | 710 000 000 | 670 000 000 |
| 4 | 710 000 000 | 630 000 000 |
| 6 | 670 000 000 | 660 000 000 |
| 8 | 230 000 000 | 400 000 000 |
| 10 | 30 000 000 | 30 000 000 |

The deterioration in sample 2 was less rapid than in sample 1 but it was below the minimal Council standard by the tenth day after the opening of the bottle. It is to be noted that this was a fresher sample than sample 1. Sample 1 was sixteen days old when the examination was started while sample 2 was examined four days after the date of production.

If Tests of viability of B acidophilus in the B A Culture product under conditions of storage at intervals during the expiration period of approximately fifty days as indicated by the firm.

The ten unopened samples were stored in a dark refrigerator at 50 F. Each bottle was used only once. It was opened for the withdrawal of a specimen and then discarded. This procedure was adopted in compliance with the firm's directions in its letter of Jan 26 1935. The results were as follows:

| Sam- ple | Date of Produce- tion | Date of Expira- tion | Date Ex- amined | Stor- age Days After | B Acidophilus Counts (Averages) | | |
|-------------|-----------------------------|----------------------------|--------------------|-------------------------------|------------------------------------|-------------------------------|--|
| | | | | | Pro- duc- tion | B B Labo- ratory Medium | Tomato Agar Under Carbon Dioxide |
| 9 | 2/11/35 | 3/28/35 | 2/27/35 | 16 | 49 000 000 | 55,500 000 | |
| 10 | 2/11/35 | 3/28/35 | 2/27/35 | 16 | 67 600 000 | 69,500 000 | |
| 11 | 2/11/35 | 3/28/35 | 3/ 3/35 | 20 | 85 000 000 | 85 000 000 | |
| 12 | 2/11/35 | 3/28/35 | 3/ 3/35 | 20 | 67 000 000 | 74 000 000 | |
| 6 | 2/ 6/35 | 3/20/35 | 3/ 8/35 | 30 | 4 000 000 | 3 000 000 | |
| 7 | 2/ 6/35 | 3/20/35 | 3/ 8/35 | 30 | 12 000 000 | 9 000 000 | |
| 8 | 2/ 4/35 | 3/20/35 | 3/16/35 | 40 | 500 000 | 1 500 000 | |
| 8 | 2/ 6/35 | 3/20/35 | 3/16/35 | 40 | 600 000 | 820 000 | |
| 4 | 1/ 2/35 | 3/21/35 | 2/21/35 | 50 | 1 000 000 | 1 000 000 | |
| 5 | 1/ 2/35 | 3/21/35 | 2/21/35 | 50 | 3,000 000 | 1 000 000 | |

These tests show that with one exception (sample 1) none of the purchased specimens examined contained 100 000 000 viable B acidophilus organisms at ten day periods within sixteen to fifty days after the dates of manufacture. The tests of samples 1 and 2 and other counts made by the firm and by examiners for the Council have shown that at about the date of manufacture this product contains approximately 600 to 700 million viable acidophilus organisms per cubic centimeter. The loss of viability that occurs, even under conditions specified by the B B Culture Laboratory, Inc., is perfectly evident from these figures.

The opinion that the product is unstable and subject to great deterioration is thus confirmed.

Attention is called to the fact that the firm's own special medium was used in accordance with directions received from the firm and was no better than tomato agar for these counts.

The colonies of B acidophilus were larger in the B B medium. They were surrounded by an opaque zone, giving the impression that there is some acid-precipitable material, possibly a protein in the B B Laboratory medium.

The type of colony from the B A Culture in B B medium was round very compact, with well defined edges and occasional filamentous projections. In general, they appeared to be of the so-called intermediate type, as were also colonies of the same culture in tomato agar. They resembled the colonies of lactobacilli from grain more than the colonies of a typical rough strain known to be derived from the intestinal tract of man. The typical X strain did not produce a precipitate in the B B Laboratory medium.

The Council on Pharmacy and Chemistry reaffirmed its decision to omit from New and Nonofficial Remedies the Bacillus Acidophilus Culture (B A Culture) product of the B B Culture Laboratory, Inc., because the product is unstable and is subject to rapid deterioration, and, further because there is insufficient evidence to support the therapeutic claims made for the product by the B B Culture Laboratory, Inc.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

RAYMOND HERTWIG, Secretary

WITHDRAWAL OF ACCEPTANCE

COCOMALT

Manufacturer—R B Davis Company, Hoboken, N J

Description—Mixture of sucrose, skim milk, cocoa, malt extract, vanilla flavoring and added vitamin D (irradiated ergosterol) 81 U S P units per ounce.

Withdrawal of Acceptance—Under date of November 6 the manufacturer requested withdrawal of acceptance from Cocomalt which has been accepted since March 1932 (THE JOURNAL, June 4, 1932, p 1991). Reasons for requesting withdrawal were not stated.

Submission of Cocomalt for acceptance was entirely voluntary on the part of the manufacturer. The product was accepted with the understanding that both the product and its advertising would be maintained in complete accord with published Rules and Regulations and General Decisions of the Committee. Manufacturers of accepted foods assume no other obligations with respect to the Committee or the American Medical Association. There are no charges accompanying the initial acceptance of foods nor subsequently.

In accordance with the request, Cocomalt will no longer be listed as an accepted food nor the company privileged to display the Committee seal on the package label or in advertising.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

ADVERTISING BOOKLET "THE HAWAIIAN ISLANDS AND THE STORY OF PINEAPPLE"

Sponsor—American Can Company, New York.

Description—Popular booklet descriptive of the Hawaiian Islands, circumstances surrounding early discovery of the pineapple, development of the pineapple industry, and modern methods of cultivation, harvesting and packing the fruit. A brief statement of the food value of canned pineapple and suggestions and recipes for its use in cookery are included.

DIXIE BRAND SANDWICH BREAD DIXIE BRAND TWIST BREAD

Manufacturer—Malbis Bakery Company, Mobile, Ala.

Description—Prepared from flour, water, sugar, whole milk, lard, skim milk, salt yeast, malt extract, and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate (method described in THE JOURNAL, March 5, 1932, p 817).

LADY CLARE BRAND EVAPORATED MILK

Distributor—M Muskal Chicago

Manufacturer—The Oatman Condensed Milk Company, Dundee, Ill.

Description—Canned, unsweetened evaporated milk. The same as Oatman's Brand Evaporated Milk (THE JOURNAL, April 16, 1932 p 1376).

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, DECEMBER 21, 1935

THE ELEVENTH REVISION OF THE PHARMACOPEIA OF THE UNITED STATES OF AMERICA

One hundred and twenty years has passed since Dr Lyman Spalding, a physician, issued a call for "gentlemen, willing to act and men distinguished for their ability and learning" to formulate a pharmacopeia. Their object was to "select from among substances which possess medicinal power, those, the utility of which is most fully established and best understood, and to form from them preparations and compositions in which their powers may be exerted to the greatest advantage." These articles were to be distinguished by "convenient and definite names."

During its early history the Pharmacopeia was decidedly an undertaking by physicians. Gradually the necessity for pharmaceutical advice developed, and the revisions of the last three editions have been dominated largely by those representing pharmacy rather than medicine. In the 1920 revision there was a fortunate agreement whereby the scope of the pharmacopeia was left entirely to the medical members of the Revision Committee even though they composed only one third of the group, the pharmaceutical interests were responsible for questions of pharmacy. Before the issuance of a new Pharmacopeia, pharmaceutical schools, medical schools, societies, certain government agencies and other organizations send delegates to the Pharmacopeial Convention. In 1930, at Washington, pharmaceutical interests, with certain manufacturing interests, gave little heed to those representing scientific and progressive medicine. Fortunately, Dr E. Fullerton Cook who had successfully revised the previous edition of the Pharmacopeia, was appointed chairman of the Revision Committee.

The new Pharmacopeia is now at hand. While this Pharmacopeia has lacked the able judgment of some of the most valuable leaders in pharmacology and medicine, owing to the 1930 political manipulations,¹ the book is to be commended. Evidently under the successful guidance of Dr Cook the members have

given serious consideration to the admonitions of the medical profession. The new Pharmacopeia follows the old one in style and general method of presentation. The progress of the revision may be measured in part by the deletions.² The committee reports that 119 products have been deleted either because they had been superseded by better products pharmaceutically or medically or because their period of usefulness had expired in view of more modern methods of treatment.

The new additions to the Pharmacopeia, of which there are fifty-eight, include Calcium Gluconate, Carbon Dioxide, Chiniofon Powder, Ephedrine and the Hydrochloride and Sulfate, Ethylene, Histamine Phosphate, Iodophthalein Soluble (Tetraiodophenolphthalein Sodium), Merbaphen, Mercuric Succinimide, Mild Tincture of Iodine, Neocinchophen and Parathyroid Solution. Thirty-nine of the new additions are already familiar to physicians in New and Nonofficial Remedies, sixteen are so well established that they appear in Useful Drugs. Of course there are a number of drugs without which the physician cannot practice successfully which are not included in the Pharmacopeia. This is in accord with the recognized policy of the Pharmacopeia that monopolized substances are not admissible, thus, as long as there is a patent for insulin it cannot be admitted. There are also other drugs, such as certain mercurials, arsenic preparations and antiseptics, for which the physician will continue to rely on New and Nonofficial Remedies for his guidance. It would seem well, if an interim revision is issued, that a shorter acting barbiturate be included. For instance, pentobarbital sodium is a nonproprietary drug having the necessary short-acting attributes.

It will be well for physicians to notice that the forthcoming edition of the Pharmacopeia has made one radical change in the matter of percentage. In the introduction it is stated that the percentage shall be "weight in volume" unless otherwise indicated. This means that in each prescription containing such heavy substances as glycerin the total amount of the other

1 A discussion of the 1930 convention appears in THE JOURNAL May 24 1930 p 1707

ingredient(s) will have a different value than if the usual weight/weight method of expression were employed in terms of percentages

Within the last two years the Committee on Revision in cooperation with the Board of Trustees of the U S Pharmacopeial Convention has initiated a practice of issuing an "interim revision" This has now become an established policy It has the advantages of early correction of serious mistakes and the necessity of making products conform with new manufacturing processes However, it has the decided drawback of requiring the physician to keep constantly in mind any possible changes which the committee may issue affecting prescription practice and may easily become a hardship on manufacturers It is hoped, therefore, that these revisions will be issued most conservatively

The nomenclature used in certain instances in the new Pharmacopeia is unfortunate For instance, physicians are asked to prescribe "Theophylline with Ethylene Diamine," a most difficult term to write in prescriptions, when there was already available to the Pharmacopeia the nonproprietary name Aminophylline At the last moment the Pharmacopeia has included the name Aminophylline as a synonym It has also used the cumbersome term of the British Pharmacopeial Commission, "Solution of Irradiated Ergosterol," when the nonproprietary name "Vioosterol in Oil" would have been simpler In the interest of the medical profession THE JOURNAL will continue to use the terms Aminophylline and Vioosterol in Oil There are, of course, many changes in spelling, such as the ph in sulphur changed to f As has so often been said, common usage establishes a name Seldom did one use the word "Gluside" in prescribing saccharin, so the Pharmacopeia has reverted to the old term "Saccharin" Names and standards for the ten newly admitted biologicals (a Typhoid, a Typhoid-Paratyphoid and Rabies Vaccines, Scarlet Fever Streptococcus Toxin and the Antitoxin, Diphtheria Toxin and the Toxin for Schick Test, Antipneumococcic (Type I) and Antimeningococcic Serums, and Old Tuberculin) were provided by the National Institute of Health A subcommittee on vitamins, responsible for the Interim Revision of Cod Liver Oil, will oversee standards on this vitamin A and D containing substance The International Units of vitamins A and D and digitals have become the official U S P units, with some modifications It is interesting to note the description of liver and stomach preparations Here no standards are given, but the Pharmacopeia endeavors to control these products with the following statement "This Board will indicate liver and stomach preparations which are of Pharmacopeial quality—as indicated by submitted clinical data" There have been some who have questioned the constitutionality of the Pharmacopeia since, in effect, it confers on an individual (corporation) legal prerogatives that are possessed only by the government Some have taken issue on each side of this question In view

of the recent decisions of the Supreme Court on the NRA, reference to an advisory committee of the determination of the acceptability of liver preparations is doubtful from a legal point of view

Of course many of the drugs that were in the Pharmacopeia have been transferred to the National Formulary, long a repository of discarded drugs An interesting conflict arises, however The new National Formulary,³ also now available, has made official certain ampule dosage forms, for instance, ampules of dextrose are now described By interpretation, ampules of other dosage forms of Pharmacopeial drugs may be looked on as nonofficial preparations The National Formulary states that ampules of dextrose "contain a sterile solution of approximately 50 Gm of anhydrous dextrose," yet anhydrous dextrose is not official in the Pharmacopeia or the National Formulary If a physician should prescribe a solution of dextrose, but not in ampule form, there would be dispensed the hydrous dextrose of the Pharmacopeia This alone would lead to an error of 5 Gm in 100 cc of a 50 per cent solution

For the most part the latest edition of the Pharmacopeia is indeed a credit to the Revision Committee THE JOURNAL and the Council on Pharmacy and Chemistry have consistently urged that physicians prescribe official preparations whenever possible⁴

LEGISLATION PENDING IN CONGRESS CONCERNING FOOD, DRUGS, COS- METICS AND THERA- PEUTIC DEVICES

Since Senator Copeland first introduced the so-called Tugwell food, drug, therapeutic device and cosmetic bill¹ in the Senate, in the Seventy-Third Congress, numerous other bills of similar purpose have been offered in both the Senate and the House of Representatives Those introduced in the Seventy-Third Congress died when that congress expired, Jan 3, 1935 Such bills² as have been introduced in the Seventy-Fourth Congress are still pending Outstanding among these is S 5, introduced by Senator Copeland and commonly called the Copeland bill It is officially entitled "An Act To prevent the adulteration, misbranding, and false advertising of food, drugs, devices, and cosmetics in interstate, foreign, and other commerce subject to the jurisdiction of the United States, for the purposes of safeguarding the public health, preventing deceit upon the purchasing public, and for other purposes"

The Copeland bill, after many amendments and in a form much different from that in which it was introduced, was passed by the Senate, May 28, 1935 It then went to the House of Representatives, where it was referred to the Committee on Interstate and

³ Comment on the National Formulary VI will appear in next week's issue of THE JOURNAL

⁴ In following this policy the Council on Pharmacy and Chemistry has in course of preparation an Epitome of the U S Pharmacopeia and the National Formulary revised in accordance with the new additions

¹ Seventy Third Congress S 1944

² Seventy Fourth Congress S 5 S 580 H R 3972 H R 6145, H R 6688 H R 6906 H R 8744 H R 8805 H R 8941

Foreign Commerce, which in turn referred it to a subcommittee, along with other bills of similar purport. The subcommittee has given extensive hearings on these bills and now has them under consideration. It may be expected to report to the full committee shortly after Congress convenes next January. The committee, after considering the subcommittee's report, will then report a bill to the House of Representatives. This bill may be either the Copeland bill in the identical form in which it passed the Senate, or the Copeland bill with amendments, or an entirely new bill possibly composed of the good features of all pending legislation. The bill reported by the committee will then take its place on the House calendar and, depending on parliamentary procedure, come before the House for debate and action. If it passes, it will in the ordinary course of events be returned to the Senate. The differences in the bill as passed by the two bodies will be adjusted through conference committees before the bill is eventually sent to the President for action.

If such a bill is passed and approved by the President, it will become a law on the day the President signs it unless some other day is named in the bill. In bills of this character it is customary to provide that the bill, in whole or in part, shall not become effective until some date considerably after the date of approval, so that business may adjust itself to the requirements newly imposed on it. The Copeland bill provides a waiting period of twelve months after its approval before its penal provisions become effective.

Every one interested in the enactment of federal food and drug legislation better than that which now prevails and in the extension of such legislation to protect the public against fraud and danger in cosmetics and prophylactic and therapeutic devices must recognize that the present Copeland bill is the result of many compromises. On its face, the bill may appear to be materially more rigid in its requirements than the Food and Drugs Act of 1906. It does cover cosmetics and therapeutic devices, which existing law does not cover at all. It is more rigorous in its requirements on the labeling of foods and drugs and in covering advertising as well as labeling. A careful study, however, discloses loopholes and evidences of weakness in its administrative provisions, particularly with reference to drugs, including "patent" and proprietary medicines, and prophylactic and therapeutic devices. These should be corrected before the bill is enacted.

A critical analysis of the Copeland bill now pending before the subcommittee of the Committee on Interstate and Foreign Commerce of the House of Representatives, by the Bureau of Legal Medicine and Legislation of the American Medical Association, appears elsewhere in this issue.³ The subcommittee, it is hoped, will develop a bill free from such defects as are pointed out in this analysis. Legislation should be enacted in a form better designed for the protection of the consumer

than is the present bill. The Association and its several constituent state associations and component county societies, and Fellows and members of the Association individually should do what they can to bring about that result.

Current Comment

ANTHRAX IN IMPORTED HAIR

Anthrax is unique in many ways in the history of bacteriology. Robert Koch's demonstration in 1876 of the anthrax bacillus as the cause of this disease was in fact the beginning of modern bacteriology. Davaine in 1863, however, had produced experimental infections with blood containing anthrax bacilli and suggested an etiologic relation. Anthrax is primarily a disease of herbivorous animals, especially sheep, cattle, goats, hogs and horses. In some European and Asiatic countries, thousands of animals succumb to this infection each year. In America the disease occurs infrequently in man. The Bureau of the Census reports that nine deaths from anthrax occurred in the United States in 1934, eleven in 1933 and twelve in 1932. Now comes a record of the occurrence of ten cases in the last two years in Delaware County, Pa. A mill that imports goat hair from China and India for the manufacture of inner lining had been in operation more than twenty years without ever having a case of anthrax until March 1933. Gold¹ reports ten cases, seven of which occurred in persons working in the mill and two in children living in the village surrounding the mill, the remaining case occurred at a distance, the infection having been carried from the mill either by shipping cases or by hair bobbins. The diagnosis in each case was confirmed by bacteriologic cultures. The first case developed in a youth, aged 18, who scratched his face while working in the carding room. A typical anthrax lesion developed, together with edema over an area 3 inches in diameter. The patient was treated by the local administration of antianthrax serum into the affected area, as well as by intravenous injections. However, the disease spread and the patient died in about five days from the time his face was scratched. It was thought that the local administration of the antianthrax serum possibly encouraged the spread of the infection in this case by the mechanical separation of the tissues. Serum was not administered locally in any of the other nine cases, and all the patients recovered. Following the optimal dose of antianthrax serum administered either intramuscularly or intravenously, definite results promptly occurred, the temperature and pulse rate dropped and the edema disappeared in a short time. However, neither the adenopathy nor the anthrax bacilli were so promptly affected, and in some cases anthrax bacilli were recovered from the lesions late in the course of the disease, when the patients seemed to be practically well. Fortunately, antianthrax serum did not produce in these cases any severe reactions, even though enormous doses were given. As much as 1,000 cc of serum as the initial dose was given, followed later by one or more injections of 100 cc each.

¹ Gold, Herman. Studies in Anthrax. Clinical Report of Ten Human Cases, *J. Lab. & Clin. Med.* 21:134 (Nov.) 1935.

into the muscles. While other patients received smaller initial doses, the average total amount given to the patients who recovered was 943.3 cc. Neoarsphenamine in addition to the antianthrax serum was used in some of the earlier cases but was discontinued, as it did not seem to be of benefit. The facts brought out in the investigation show that this strain of anthrax bacilli was especially virulent. Two cases occurred one year after the last previous case developed, and yet during that time there had been no change in the raw material used at the mill or in its processing. Were the last two cases a recurrence of the previous infection or was a new shipment of hair, which had just arrived from the Orient, responsible for the fresh outbreak? Bacteriologic tests on the new bales of hair showed that anthrax bacilli were present in the center of a bale as well as in sweepings of the storeroom floor. These ten cases indicate that it is possible for products infected with virulent anthrax organisms to be shipped into the United States without detection, even though quarantine regulations to prevent such disasters are operating.

DISTRIBUTION OF PHYSICIANS UNDER INSURANCE

An oft repeated indictment against the system of private practice of medicine in the United States is that it leads to an inequitable distribution of medical facilities. The advocates of compulsory sickness insurance and 'socialized' medicine cite the fact (unaccompanied by an analysis of population charac-

* Outside Saar

† Average for all Prussia

teristics) that in 1931 there were 614 persons per physician in New York and 1,400 in South Carolina as evidence of the need to introduce insurance or some similar scheme as a means of distributing physicians more closely in relation to population. Prussia has had compulsory sickness insurance for more than half a century. The accompanying table is the result of a recent study of the distribution of physicians in Prussia¹

¹ Humboldt H. Medical Care in Prussia in the Years 1824 and 1932. *Deutsches Arzteblatt* 66: 854 (Sept. 7) 1935.

Although Prussia is smaller than most American states and there is a much more uniform distribution of population than in the United States as a whole, the differences in the distribution of physicians reach the extreme of 625 and 884 persons per physician in two provinces with the most physicians, to 3,003 and 2,651 in those with the least number of physicians in proportion to population.

Medical facilities, like all other facilities, in a competitive society, follow purchasing power, and purchasing power is not increased by any system of distribution through insurance, or otherwise.

Association News

RADIO BROADCASTS

The American Medical Association broadcasts over the Blue network and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers a toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The next three programs are as follows:

December 24 No broadcast
December 31 No broadcast
January 7 Winter Ills Morris Fishbein, M.D.

This program is broadcast also on the short waves through KDKA, Pittsburgh, over station W8XK, 11,870 and 12,210 kilocycles.

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Annual Registration Due January 1—Every licensee of the Arkansas Eclectic Medical Examining Board must register annually with the secretary of the board between January 1 and the last day in February and pay a fee of \$2, if a resident of Arkansas, and of \$4, if a nonresident. The failure of a licensee to pay the required fee by March 1 automatically suspends his right to practice while delinquent. If he fails for three successive years to pay the required fee, his license is to be canceled and thereafter will be reinstated only on such a showing to the board of moral character and professional qualifications as would entitle the applicant to the issuance of an original license and on the payment of the same fees as are required for the issuance of an original license.

CONNECTICUT

Society News—At a meeting of the Windham County Medical Society recently, speakers included Drs. Erwin C. Miller, Worcester, Mass., and Cecil R. Garcin, Danielson, on pneumonia and cancer, respectively.—Dr. Bret Ratner, New York, addressed the Hartford Medical Society at Hartford, November 18, on allergy in childhood.

Personal—Dr. Ross G. Harrison, Sterling professor of biology at Yale University School of Medicine, New Haven, received an honorary degree from the University of Budapest at the tercentenary celebration of the university.—Dr. Clifford D. Moore, formerly chief executive officer, Boston Psychopathic Hospital, has been appointed superintendent of the Fairfield State Hospital, Newton, succeeding Dr. Roy L. Leak.

DISTRICT OF COLUMBIA

University News—Dr Siegfried Thannhauser, formerly director of the medical clinic and professor of internal medicine at the University of Freiburg-i-Br, Germany, and now of Boston, gave the second lecture in the Smith-Reed-Russell series at George Washington University School of Medicine, November 26, his subject was "Cholesterol Its Chemical, Physiological and Clinical Aspects"

Society News—The Medical Society of the District of Columbia was addressed, November 22, by Drs J Tate Mason, Seattle, and James S McLester, Birmingham, Ala., President-Elect and President of the American Medical Association, respectively, they spoke on "Etiology and Treatment of Peptic Ulcer" and "Influence of Food in Digestive Disorders" Among others, Dr Edward A Cafritz addressed the society, December 11, on "Nondrainage Appendiceal Peritonitis"

ILLINOIS

Society News—Dr Anton J Carlson, Chicago, discussed "Advance in Medicine Through Animal Research" before the Fulton County Medical Society in Canton, November 25—At a meeting of the Sangamon County Medical Society in Springfield, December 5, Dr Paul B Magnuson, Chicago, spoke on "Surgery of Arthritis"—Dr Jack L Diamond Alton, addressed the Alton Medical Society, November 14 on "Value of Malaria Therapy in the Treatment of Paresis"

Chicago

Dr Houssay to Address Institute of Medicine—Dr Bernardo A Houssay, professor of physiology, National University of Buenos Aires, Argentina, will deliver an illustrated lecture before the Institute of Medicine of Chicago January 3, on "Interactions Between the Parathyroid Glands and the Hypophysis and Pancreas"

University News—Construction will soon begin on a three story addition to the Surgical Institute for Crippled Children at the University of Illinois College of Medicine The building is to cost about \$150,000 and will provide forty additional beds—A symposium on poliomyelitis was presented before the Volini Medical Society at Loyola University School of Medicine in November by Drs Archibald L Hoyne and Victor E Gonda The Volini Medical Society is an honorary society, its membership limited to those members of the junior and senior classes who have maintained honor grades in medicine

Conference on Mental Hygiene—The Illinois Society for Mental Hygiene sponsored a one day conference, December 6, to discuss the modern concepts and practice of mental hygiene Speakers included

William E Blatz, Ph D associate professor of psychology University of Toronto Mental Hygiene Concepts in Present Day Thought
Marion Faber assistant director in charge psychiatric nursing service Cook County School of Nursing Psychiatric Nursing
Dr Franz G Alexander director Institute for Psychoanalysis Psychoanalysis

Dr Samuel H Kraines associate in neuropsychiatry University of Illinois College of Medicine Psychobiological Aspects

Dr William Malamud professor of psychiatry State University of Iowa College of Medicine Iowa City Psychotherapeutic Techniques in Personality Adjustments

Speakers at the dinner meeting included Dr Ralph C Hamill who presided Helen L Myrick, general director of the Illinois Society for Mental Hygiene, and Dr Clarence M Hincks, director, National Committee for Mental Hygiene, New York.

INDIANA

Society News—A symposium on syphilis was presented before the Indianapolis Medical Society, December 17, by Drs John R Thrasher, John R Brayton, Robert G Thayer and Russell L Arbuckle.—The Noble County Medical Society was addressed in Kendallville, December 3, by Dr Marshall B Catlett, Fort Wayne, on "Surgical Treatment of Female Pelvic Disease"—At a meeting of the Fort Wayne Medical Society, December 3, Dr Louis J Hirschman, Detroit, discussed "Extracolonic Factors in the Etiology of So-Called Colitis"—Dr Oscar O Miller, Louisville, addressed the Jefferson County Medical Society in Madison November 26, on "Modern Treatment of Pulmonary Tuberculosis"—At a meeting of the Vigo County Medical Society in Terre Haute, November 12, Dr Walter E Stewart, Terre Haute, spoke on sinusitis.—The Vanderburgh County Medical Society was addressed in Evansville November 12, by Dr Julius R Yung, Terre Haute, on "Toxic Diffuse Goiter—Its Diagnosis and Treatment."

IOWA

Personal—Dr Ralph H Heeren has been appointed associate professor of hygiene, preventive medicine and bacteriology at the State University of Iowa College of Medicine, Iowa City, succeeding Dr Albert V Hardy, who, it is reported, has gone to Johns Hopkins University, Baltimore.

Examination in Basic Sciences—The Iowa Board of Examiners in the Basic Sciences will conduct a written examination at the state capitol, Des Moines, January 14, at 9 a. m. Those wishing to take the examination must first obtain an application blank from the secretary, fill it out and return it, together with the fee of \$10, so as to reach the secretary not later than Monday, December 30 Edward A. Benbrook D V M, Iowa State College, Ames, is secretary of the Iowa Basic Science Board.

Society News—Dr Julian D Boyd, Iowa City, discussed tuberculosis in childhood before the Johnson County Medical Society at the Oakdale Sanatorium, November 6—Speakers before the Scott County Medical Society in Davenport recently included Dr William P Murphy, Boston, on "Modern Treatment of Anemia"—At a meeting of the Woodbury County Medical Society in Sioux City recently Drs William E Ash, Council Bluffs, spoke on "Relationship of Psychiatry to General Medicine", Eugene B Floersch, Council Bluffs, "Coronary Thrombosis," and Lloyd G Howard, Council Bluffs, "Head Surgery"—Dr Lonnie A Coffin, Farmington, was chosen president of the Southeastern Iowa Medical Society recently, speakers at the meeting included Dr Arnold S. Jackson, Madison, Wis, on "Diseases of the Thyroid Gland."—Dr Walter L. Bierring, Des Moines, among others, addressed the Wright County Medical Society, November 25 on the prevention of disease and the responsibility of the state health department—Dr Albert M Snell, Rochester, Minn., will speak before the Linn County Medical Society, January 9 in Cedar Rapids, on "Differential Diagnosis of Conditions Associated with Jaundice"

MINNESOTA

Personal—Dr Fred G Carter, superintendent of Ancker Hospital, St Paul has resigned to accept a position at Christ Hospital, Cincinnati, he will be succeeded by Dr Seymour R. Lee, who formerly was on the staff of the hospital but recently has been at the state hospital at Willmar Dr Carter has been associated with Ancker Hospital for fifteen years—Dr Milburn W Kemp of the Fergus Falls State Hospital has been appointed superintendent of the state hospital at Anoka to succeed the late Dr Arthur C Came—Dr Thomas H Dickson Jr has been appointed medical director of the Minnesota Mutual Life Insurance Company to succeed Dr Charles N McCloud—Dr Magnus C Petersen, assistant superintendent of the St. Peter state hospital since Jan 1, 1928, has been named superintendent of the Willmar State Asylum by the Minnesota Board of Control

MISSOURI

Medical Information Bureau—In accordance with a decision by its house of delegates, the Missouri State Medical Association has established a medical information bureau in its office in St Louis to facilitate the dissemination of authentic information on public health matters to the public, the press, and charitable organizations and association members, to expose and suppress quackery and to promote a better understanding between the public and organized medicine The bureau maintains a card index file on proprietary medicines, physicians and institutions One hundred members of the society were appointed as advisers to be consulted in answering inquiries not of a routine nature or which deal with a special field of medicine or medical problems Dr Edward J Goodwin secretary of the state association, is in charge of the bureau.

NEBRASKA

Survey of Cancer in Nebraska—The official report of a survey of the cancer problem in Nebraska, made in 1934 by Dr Frank L Rector, field representative of the American Society for the Control of Cancer, at the request of the Nebraska State Medical Association, was published in the *Nebraska State Medical Journal* in November The death rate from cancer in Nebraska was found to have increased from 75.4 per hundred thousand in 1920 to 102.5 in 1932, an increase comparable to that for the U S registration area as a whole In the decade 1920-1930 the population 30 years of age and over increased only 37 per cent, while the cancer death rate increased 38.3 per cent Cancer caused 11 per cent of all Nebraska deaths in 1932 and, of the 1,424 deaths, 57.2 per cent

were from cancer of the digestive tract and peritoneum. At the time of this survey seventy-five counties in Nebraska, containing 52 per cent of the population and nearly 42 per cent of the physicians of the state, were without hospitals of twenty-five beds or more. Twenty-eight hospitals located in fourteen counties furnished information concerning cancer patients cared for in 1933 and facilities for diagnosis and treatment. There were 1,355 cancer patients hospitalized in 1933, of these 184 died and eighty-two came to necropsy. Only 12.9 per cent of all cancer deaths in the state took place in hospitals. All general hospitals take cancer patients. Nine are equipped with x-ray apparatus of 200,000 volts capacity, the Lincoln General Hospital has equipment of 800,000 volts capacity. Three hospitals own a total of 256 mg of radium, and private physicians as far as could be ascertained, own 835 mg. Eleven of the hospitals have no facilities for laboratory examination of tissues, but four of these send tissues to pathologists of recognized standing. Six hospitals reported no necropsies although they reported 164 deaths from all causes. Seven other hospitals reported a total of 438 deaths, of which only forty-two cases came to necropsy. Two tumor clinics were in operation in Omaha and one was being organized in Lincoln at the time of the survey. Dr. Rector outlined detailed activities that could be undertaken by the state medical association, the state department of health and the state committee of the American Society for the Control of Cancer.

NEW JERSEY

Fined for Recording Blood Pressure on Boardwalk.—Harry Forman, who operated a stand on the boardwalk at Atlantic City where he made blood pressure readings was arraigned in district court, October 23, before Judge W. Lindley Jeffers, who fined him \$200 but suspended the fine. Forman was investigated by the state medical board and the Atlantic County Medical Society after protests were received from about 175 physicians who visited Atlantic City at the annual session of the American Medical Association last June. It was said. Forman contended that he was not practicing medicine but that his machine was similar to a weight machine. The *New York State Journal of Medicine* printed in its November 15 issue a letter from the president of the Taylor Instrument Companies, Rochester, N. Y. deploring misuse of instruments produced solely for the medical profession. The letter requested that the company be given any information concerning the way these instruments are procured for unethical purposes so that steps may be taken to prevent continuance of the practice.

NEW YORK

Personal.—Dr. Louis C. Kress, director of the New York state division of cancer control has been appointed chairman of the state cancer committee of the American Society for the Control of Cancer, succeeding Dr. Burton T. Simpson. At the recent meeting of the New York State Association of Public Health Laboratories, a medal was presented to Mary B. Kirkbride, Sc.D., associate director of laboratories of the state department of health, in appreciation of her services as secretary of the association during the past fifteen years. A portrait of Dr. Leroy W. Hubbard, Mount Vernon, N. Y. was presented to the Georgia Warm Springs Foundation Warm Springs, Ga. Thanksgiving Day, by former patients. Dr. Hubbard was the first physician to be connected with the foundation serving as surgeon-in-chief from 1926 to 1931 when he resigned to do extension work for the institution. He was succeeded at Warm Springs by Dr. Michael Hoke. Prior to this appointment, Dr. Hubbard had been orthopedic surgeon with the New York State Health Department for nine years.

New York City

Analysis of Poliomyelitis Outbreak.—The New York City Department of Health has published a preliminary report on the poliomyelitis epidemic of last summer which reached the highest number of cases since 1931. About 1,900 cases had been reported up to October 1 compared with 4,138 in 1931 and 9,023 in 1916. The peak of the outbreak was reached August 24. Comparison with earlier outbreaks shows that there has been a definite shifting of incidence to higher ages. 86.6 per cent of the cases in 1907 were in children under 5 years old, while in 1935 only 32.8 per cent occurred in this group with 41.9 per cent in the group 5 to 9 years old. The virulence has varied in the four principal epidemics. In 1907 the case fatality rate was estimated at 5 per cent, in 1916 it was 27.3 in 1931 it was 12.18 and in 1935 it was 4 per cent. After deliberation, it was decided to open the city schools at

the regular time, and it is believed that this policy was proved sound by the fact that no increase in prevalence followed the opening of schools.

Municipal Health Building Opened.—New York's \$4,550,000 ten story building for the departments of health, hospitals and sanitation, which has been under construction for four years, was dedicated November 26. Speakers included Mayor La Guardia, Dr. John L. Rice, commissioner of health, Dr. Sigismund S. Goldwater, commissioner of hospitals, Thomas W. Hammond, commissioner of sanitation, Dr. John A. Hartwell, director of the New York Academy of Medicine, and Dr. Thomas A. Gonzales, acting medical examiner. The design of the building was described as "conservatively classic" harmonizing with other civic units in the area. The main entrance is on Worth Street and the other sides face Center, Lafayette and Leonard streets. On the façades are carved names of prominent public health figures from Moses to Dr. Hermann M. Biggs. The names are Moses, Jenner, Ramazzini, Hippocrates, Paracelsus, Pinel, Lind, Koch, Behring, Pasteur, Leeuwenhoek, Ehrlich, Billings, Harvey, Farr, Howard Lister, Nightingale, Shattuck, Morton, Marion Sims, Bard, Semmelweis, Welch, Stephen Smith, E. B. Dalton, Biggs, Walter Reed and Gorgas. Fifty years ago the department of health was at 300 Mulberry Street, in 1889 the offices were moved to the criminal courts building, later to a building at Fifty-Fourth Street and Sixth Avenue, and then to the Excelsior Building in Center Street. From 1919 till the new building was begun the headquarters were at 505 Pearl Street and during the past four years they were at 139 Center Street.

NORTH CAROLINA

Health Bulletin Fifty Years Old.—With its December issue the *Health Bulletin* of the North Carolina State Board of Health completed fifty years of publication. It was founded by Dr. Thomas Fanning Wood, the state's first health officer who was a practicing physician of Wilmington. Dr. George M. Cooper, assistant state health officer and director of the division of preventive medicine of the state board of health, Raleigh, has been editor since 1923.

Graduate Course in Gastro-Intestinal Diseases.—A graduate course in gastro-intestinal diseases was presented at Duke University School of Medicine, Durham, October 31-November 2. Speakers included Drs. James S. McLester, Birmingham, Ala., President, American Medical Association, Thomas R. Brown, Arthur M. Shipley, Dean Lewis and Harvey B. Stone, Baltimore, Walter C. Alvarez and Byrl R. Kirklin, Rochester, Minn., Hugh H. Trout, Roanoke, Va., William Weston and LeGrand Guerry, Columbia S. C., Walter B. Martin and Robert L. Payne, Norfolk, Va., Martin E. Rehfuess, Philadelphia, Thomas T. Mackie, New York, Fred W. Rankin, Lexington, Ky., Frank K. Boland, Atlanta, Ga., Anton J. Carlson, Chicago, and John Shelton Horsley, Richmond, Va.

OKLAHOMA

County Quarantined for Meningitis.—Kiowa County was placed under quarantine December 13 because of an outbreak of meningitis that caused at least one death and thirteen illnesses in the county, which has a population of 26,000. The quarantine was lifted from most of the area two days later after a conference between the state health commissioner, Dr. Charles M. Pearce, and county authorities, but it was enforced by the national guard in the communities of Snyder and Mountam Park. Dr. James L. Adams, Hobart, Kiowa County health officer, ascribed one death definitely to meningitis and said that nine other recent deaths may have been caused by the disease. Public assemblages were forbidden and grocery and drug stores were directed to serve only by delivery and then with extreme caution.

Society News.—Dr. Ian MacKenzie addressed the Tulsa County Medical Society, Tulsa, November 11, on "Congenital Deformities." Drs. Charles H. Eads and Anna Luvern Hays spoke November 25, on "Management of Syphilis in Pregnancy and Treatment of Congenital Syphilis," respectively. The Muskogee Academy of Medicine at an all day meeting in Muskogee December 4 had as guests Drs. Peter T. Bohan and Charles C. Denme, Kansas City, Mo., and John C. Burch, Nashville, Tenn. Drs. Anson L. Clark and Henry H. Turner, Oklahoma City, addressed the Osage County Medical Society, Pawhuska recently on "Fever Therapy, Its Possibilities and Limitations" and "Recent Advances in Endocrinology with Special Reference to the Sex Hormones, respectively." Drs. John L. Kleinhessel and Henry N. Tihen, Wichita, Kan., addressed the Woods-Alfalfa County Medical Society in Alva, November 26 on "Diabetes and Pregnancy," and Relation of Gastric and Duodenal Ulcer to Cancer."

respectively—Drs William P Neilson and Charles J Roberts, Enid, addressed the Garfield County Medical Society, Enid, recently, on "Effect of Abdominal Operations on Respiration" and "Medical Treatment of Peptic Ulcer," respectively—Speakers before the Kay County Medical Society, Tonkawa, recently, were Oklahoma City physicians Drs Ephraim Goldfain and Earl D McBride, on arthritis, and John H Robinson, significance of abdominal pains

PENNSYLVANIA

Prize Awarded—Dr Constantine P Faller, Harrisburg, received the 1935 award of the Seibert prize of \$500 for study in Europe, given by the Harrisburg Academy of Medicine. Dr Faller was honored in recognition of his work in initiating graduate medical assemblies in his community. The prize was presented at the academy's annual banquet, November 13

Society News—A conference of secretaries of county medical societies was held in Harrisburg, December 10, Dr Samuel R Haythorn, Pittsburgh, reported a survey of group hospitalization plans and Dr Rosco G Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, spoke on economic problems—Dr Truman G Schnabel, Philadelphia, conducted a clinic on cardiac and renal cases at the meeting of the Cambria County Medical Society, Johnstown, December 12

Philadelphia

Society News—Dr Bret Ratner, New York, addressed the Philadelphia Pediatric Society, December 10, on "Pathogenesis and Management of Allergy in Childhood"—Speakers at a meeting of the Philadelphia Academy of Surgery, December 2, were Drs Harry E Knox, on "Pneumococcic Peritonitis," William J Ryan, "Hernia of the Vermiform Appendix," and Harold A K Mingle, "Experimental Studies in Peritonitis"—Drs Lewis C Scheffey and William J Thudium, among others, addressed the Obstetrical Society of Philadelphia, December 5, on "Further Results in the Treatment of Carcinoma of the Cervix"—Speakers at a meeting of the Philadelphia Urological Society, November 25, were Drs Paul M Butterfield, New York, on "Urological Conditions in Childhood," Joseph C Birdsall, Relationship of Hydronephrosis to Nephrophtosis, and John T Farrell Jr and Theodore R Fetter, "Irradiation of Carcinoma of the Bladder"

Pittsburgh

Society News—At a meeting of the Pittsburgh Pediatric Society, December 13, speakers were Drs Hyman A Slesinger, Windber Pa, on "Acute Epidemic Encephalitis," James LeRoy Foster, "Present Status of Certified Milk in Pittsburgh," and William W Briant Jr, Mount Lebanon, Pa, "Complete Heart Block in a Child of Three Years"—A symposium on peptic ulcer was presented before the Pittsburgh Academy of Medicine, December 10, by Drs Frank A Evans, Frederick B Utley and John P Griffith

TENNESSEE

Health at Nashville—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million for the week ended December 7 indicate that the highest mortality rate (208) appears for Nashville and that the rate for the group of cities was 12.2. The mortality rate for Nashville for the corresponding week of 1934 was 165 and for the group of cities, 11.7. The annual rate for the eighty-six cities for the forty-nine weeks of 1935 was 11.3, and the same rate appeared for the corresponding period of last year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

TEXAS

Personal—Dr Edmond H Sauvignat, Laredo, has been appointed health officer of Webb County, succeeding Dr Albert T Cook, who became health officer of the city of Laredo—Dr Laurence J Montague has been appointed superintendent of City-County Hospital, Edinburg, succeeding Dr Cleburne M Williamson, who resigned to devote himself to private practice

Graduate Assembly at Houston—The fourth annual Post Graduate Medical Assembly of South Texas was held in Houston, December 3-5, at the Rice Hotel. Sessions were held morning, afternoon and evening with informal luncheon meetings as well. Guest speakers were Drs Edward V L Brown,

Chicago, and Edward C Ellett, Memphis, Tenn., on ophthalmologic subjects, Thomas E Carmody, Denver, and Albert C Furstenberg, Ann Arbor, Mich., on otolaryngology, William C Danforth, Evanston, Ill obstetrics, Wilbur C Davison, Durham, N C, pediatrics, Walter A Fansler, Minneapolis, proctology, Louis J Karnosh, Cleveland, psychiatry, Frank H Lahey, Boston, surgery, Oswald S Lowsley, New York, urology, John S Lundy, Rochester, Minn, anesthesia, Emil Novak, Baltimore, gynecology, Paul A O'Leary, Rochester, Minn, dermatology, Leroy Sante St Louis, radiology, Cyrus C Sturgis, Ann Arbor, Mich, internal medicine, and Philip D Wilson, New York, orthopedics. The eye, ear, nose and throat section of the assembly met jointly with the Texas Ophthalmological and Otolaryngological Society with Drs Carmody, Brown, Furstenberg and Ellett as guests

GENERAL

Examinations in Ophthalmology—The American Board of Ophthalmology will conduct examinations in Kansas City, Mo, May 11, at the time of the annual session of the American Medical Association and in New York in October. Applications and case reports must be filed sixty days before the date of examination with Dr Thomas D Allen, assistant secretary, 122 South Michigan Avenue, Chicago

International Conference on Fever Therapy—The first International Conference on Fever Therapy will be held in New York in September 1936. Therapeutic, physiologic and pathologic phases of fever will be discussed. It is planned to translate abstracts of all the papers into French, English and German. In order to make printed copies of the transactions available for the conference, it is necessary that manuscripts and abstracts be sent in not later than June 1, 1936. Those interested in participating are requested to make early application. Dr William Bierman, 471 Park Avenue, New York, is secretary. The members of the American committee are Drs Arthur U Desjardins, Rochester, Minn, William Bierman, New York, Frank W Hartman, Detroit, Leland E Hinsie, New York, Clarence A Neymann, Chicago, Walter M Simpson, Dayton, Ohio, and Stafford L Warren, Rochester, N Y

Journal on Birth Control—A periodical known as the *Journal of Contraception* appeared in November. Published by the Birth Control Clinical Research Bureau, New York, it is to be devoted to the "biological and clinical aspects of human fertility and its control" and contains one original article, editorials, abstracts of current literature and news. The following medical advisory board is announced: Calvin Bridges, Ph D, Pasadena, Calif, Robert Chambers, Ph D, New York, Norman E Hines, Ph D, Hamilton, N Y, H M Parshley, Sc.D, Northampton, Mass, and Drs Morris N Baskin, Denver, Adelaide Brown, San Francisco, Herbert M Evans, Berkeley, Calif, Alan F Guttmacher, Baltimore, James S Klumpp, Huntington, W Va, Adolf Meyer, Baltimore, James Shirley Sweeney, Dallas, Texas, Fred J Taussig, St. Louis, Ira S Wile, New York, and Prentiss Willson, Washington, D C

Society News—The annual meeting of the American Society for the Study of Arthritis was held in New York at the Waldorf-Astoria, December 12-14. Among speakers were Drs Walter S Barnhart, Ottawa, Canada, on "Some Problems of Chronic Rheumatic Diseases", Raymond L Jeffery, Seattle, "Treatment of Arthritis with Complement Fixing Reactions", Conrad Berens, New York, "Lesions of the Eye Associated with Arthritis," and Donald Gordon, New York, "Traction and Resisted Movements in Arthritis." The program of the annual open meeting was noted in THE JOURNAL, December 14, page 1995—Dr George L Wright, Syracuse, N Y, was elected president of the International Association of Fire and Police Surgeons and Medical Directors of Civil Service Commissions at the annual session in New York, November 23. Dr Karl B Bretzfelder, New Haven, was made vice president and Dr Arthur Wildman, Brooklyn, secretary. Next year's convention will be in New Haven.

Prevalence of Communicable Disease—A decrease in poliomyelitis of about 1,500 cases occurred during the four weeks ended November 2 as compared with the preceding four weeks, according to *Public Health Reports*. The 1,039 cases for the country as a whole was about 50 per cent in excess of those for the corresponding periods in 1934 and 1933, but it was only about half of the number reported for this period in each of the years 1931 and 1930. The incidence was still considerably above that of recent years in regions along the Atlantic coast where the disease has been most prevalent, but all other sections reported fewer cases than last year. The number of cases of meningococcic meningitis rose from 240 for the pre-

ceding period to a total of 273 for the four weeks period ended November 2. The increase was somewhat unexpected, because this disease is usually at or near its lowest level at this season of the year. The sharpest rise occurred in the South Atlantic region, where practically every state reported an increase over the preceding four weeks and the fifty-nine cases reported was the highest for this period in the seven years for which data are available. The incidence of typhoid continued to decline. For the four weeks ended November 2 there were 1,600 cases, the lowest figure for this period in recent years. The usual seasonal increase of diphtheria continued, with 5,416 cases reported during the four weeks analyzed.

Mr Fosdick Appointed President of Rockefeller Foundation—The retirement of Max Mason, Ph.D. president of the Rockefeller Foundation since 1929, and the appointment of Raymond B. Fosdick, New York, as his successor, have been announced by the foundation effective July 1, 1936. Mr. Mason, who will devote his time to research in mathematics and mathematical physics, left Wisconsin in 1925 to become president of the University of Chicago from where he went to the foundation in 1928 as director of the division of natural sciences, and became president in 1929. In addition to becoming head of the foundation, Mr. Fosdick will assume the presidency of the General Education Board. In explanation of the combination of offices, it was announced that the General Education Board plans to expend increasing amounts of its principal funds over a period of years, possibly resulting in their complete exhaustion, meanwhile, to avoid any overlapping of the boards, it was deemed wise to have one administration for the two. Mr. Fosdick, an attorney, has been identified with Rockefeller interests for many years, being a trustee of the organizations he now heads and of the Rockefeller Institute for Medical Research. In 1913 he made a study of police organization in Europe as a representative of the Rockefeller Bureau of Social Hygiene. Among other public positions, Mr. Fosdick has been assistant corporation counsel of New York (1908-1910), commissioner of accounts in charge of investigations of city departments (1910-1913) and a member of the New York City board of education. During the World War he served as chairman of a commission on training camp activities of the War and Navy departments, as a special representative of the War Department in France as civilian aide to General Pershing in France and in 1919-1920 was attached to the League of Nations. He was awarded the Distinguished Service Medal.

Government Services

Hospitals and Physicians Eligible for Loans Under Federal Housing Administration

Hospitals and similar institutions, whether owned and operated by individuals or corporations, are eligible for loans for modernization, repair and equipment under the Modernization Credit Plan of the Federal Housing Administration.

Physicians and surgeons who maintain their offices in buildings removed from their homes, as well as those who have their offices in dwellings, may also take advantage of the plan to have the most modern establishment and equipment.

The distinction is that the hospital, diagnostic center, or the office of the physician when it is not located in a dwelling may obtain credit, anywhere from a few hundred dollars to as much as \$50,000, while the physician is limited to a loan of \$2,000 when his office is a part of a home.

The office in a business building where frequently a number of physicians have their individual consultation rooms but use a common diagnostic center and equipment, would be eligible for credit on the same basis as a hospital. The office in a home however, would be limited to the \$2,000 maximum for modernization and repair as provided for homes.

This means briefly that any reputable institution or physician may obtain on easy terms sufficient credit to put the structure in good condition and to purchase and install the most modern equipment for diagnosis and treatment.

The Federal Housing Administration lends no money. The loans are made by private banking and financial institutions under an arrangement by which the Housing Administration insures them against loss.

Under these conditions lending institutions are more than willing to make loans that are sound business risks.

The terms are that the charge may not be in excess of the equivalent of a 5% discount for each \$100 face value of a one-

year monthly instalment note. Payments are to be divided into equal monthly instalments and may be spread over a period of as long as five years.

Equipment that would be considered eligible for an insured credit is described in the regulations as follows:

It must be of permanent, utilitarian character and of such value as to justify the application of the principle of time payment thereto. It may not include furnishings, furniture, or small portable appliances. A hospital, for instance, could obtain an eligible loan covering x-ray machine, thermal cabinets, fluoroscopes and articles of like character, but such a loan could not include surgical instruments, beds and other furniture.

This should give an understanding of the types of equipment that may be installed. The list is an elaborate one. The main consideration is that the article should have a unit value sufficient to justify the application of time payments to its purchase and should be of a durable nature with a reasonable expectancy of useful life longer than the period of the loan.

The dealer in all such equipment is in all probability familiar with the eligibility rulings of the administrator and whether the article he sells comes within the regulations adopted. If he cannot supply the information the Federal Housing Administration, Washington, D. C. will make rulings on request.

In the same manner in which equipment has outgrown its usefulness the building itself may be in need of repairs and modernization. One of the greatest essentials in a hospital is proper light. Lighting installations are eligible.

The operating room may be completely done over, the walls redone, a modern heating plant installed and ventilating or air conditioning equipment put in. The structure may be in need of a new roof, floors, glass-enclosed porches, concrete driveways, fireproofing (most important in an institution of this kind) a built-in garage, or a separate garage. It may be advisable to make some additions. In short, any structural improvements that may be done to the ordinary business establishment would be eligible for the hospital.

Since funds are advanced by banks or other private lending agencies, they are expected to exercise ordinary business precaution. Naturally a lending institution could not be expected to make a large loan to some institution when the credit rating did not justify it.

The banks are required to satisfy themselves on the question of security and the ability to repay.

Assuming these conditions to be satisfactory, there should not be the slightest difficulty in obtaining credit promptly.

Here is an illustration from Hartford, Conn. Miss Anna M. Holmquist, owner of a convalescent home, obtained a modernization credit of \$1,500 and transformed the institution into an up-to-date maternity hospital. The loan was made available within five days from the date of application. This enabled the owner to put on a new roof, new porch, copper drains and new heating system, and to modernize the interior and the operating room.

It is amazing how much may be done with a comparatively small sum particularly in the modernization of the building and the purchase of equipment. It would be well for the physician who maintains his own hospital, clinic or diagnostic center, or the group of physicians or corporations, to make a survey of their needs and either consult their banker or the Federal Housing Administration.

Extent of Rural Health Service

Public Health Reports announces the establishment of full time health service in twenty-four units during the period Jan. 1-Dec. 31, 1934. The service was discontinued in fourteen units, leaving a net gain of ten. The greatest gains were in Tennessee and North Carolina, in each of which full time health service was established in five counties. Delaware and Maryland lead in the percentage of rural population with this service, all of their counties having been provided with full time local health organizations. Health units in Delaware are provided by the state, while those in Maryland are maintained by the local governments, with or without assistance from the state health department or other sources. Of the 540 counties, townships or districts with health service under full time health officers at the end of the present calendar year, 507, or 93.9 per cent were receiving financial assistance for the support of their health service from one or more of the following agencies: state board of health, U. S. Public Health Service, the Rockefeller Foundation, the American Red Cross, the American Women's Hospital Fund, the Rosenwald Fund, the Commonwealth Fund and the Milbank Memorial Fund.

Antivivisection Hospital Abandons Its Program

For many years there has been an active antivivisection party in this country, which carries on propaganda by means of a journal, public meetings and in other ways. One is the maintenance of the National Antivivisection Hospital at Battersea (in Southwest London). This is a general hospital with a proper staff of physicians, surgeons and specialists. According to its constitution no vivisectionist was permitted to be a member of the board of the hospital or of its medical, surgical, nursing or administrative staff. No remedies that were the result of any vivisection or experiments on animals might be used there. Every person on the staff was required before joining to give a pledge against vivisection. It has now proved impossible to carry on the hospital under these conditions. In 1929 there was a large surplus of income over expenditure, but since then there has been a deficiency, particularly in the income from legacies. The hospital has had to close three wards of 100 beds. An application was therefore made to obtain the sanction of the high court of justice for abandoning the antivivisection conditions of the foundation of the charity. An affidavit, made by the senior honorary surgeon, was read, to the effect that in view of the advances in general medical knowledge it was impossible to run the hospital on the present antivivisection lines. No other hospital in England was run on antivivisection lines. A scheme was submitted to the court for power to change the name of the hospital to the Battersea General Hospital and to declare that the observance of the principles and practice of antivivisection were no longer to bind the hospital. Mr. Justice Eve said that he must approve the scheme. Though personally he sympathized with the original objects and principles of the hospital, the time had come when they were no longer practicable. Possibly the diminution of the hospital's income was due to the fact that everybody had now to pay so much in taxation that little was left for charity.

An Expensive Dermatitis

The judicial committee of the privy council (the supreme court of appeal in England for the dominions) allowed the appeal of Dr. R. T. Grant of Adelaide, South Australia, from a judgment of the high court of Australia, which allowed by a majority the appeal of the Australian Knitting Mills Ltd. from a judgment of the Supreme Court of South Australia by which it was held that Dr. Grant should recover damages amounting to \$12,250 for dermatitis contracted from the underwear manufactured by the knitting mills. Dr. Grant's claim was that the disease was contracted by reason of the presence of free sulfite in the cuffs or ankle ends of the pants that he purchased and wore, and that the presence of this substance was due to the negligence of the manufacturers. He put on the pants June 28, 1931, in the morning and by the evening felt itching on the ankles, but objective symptoms did not occur until next day, when redness appeared on each ankle. The condition got worse and he was confined to bed from July 21 for seventeen weeks. The rash became generalized and very acute. In November he became convalescent and went to New Zealand to recuperate. He returned in February and was able to resume his practice but soon had a relapse, and by March his condition was so serious that he went to the hospital for three months. For the respondents it had been argued that the disease might have been contracted from some external irritant, which implied no imperfection in the garments and did harm

only because of the doctor's peculiar susceptibility. Thus the disease might have been initiated by the mechanical irritation of the wool itself, or, if it was due to some chemical ingredient in the garment, that might have been something in itself harmless, so that the mischief was attributable to the appellant's own physical defect. It was argued that the respondents could not be held responsible for anything in the garments that would not be harmful in normal use. However, the Australian chief justice held that the doctor's skin was normal. The respondent's secretary gave evidence that they had sold throughout Australia 4¾ millions of garments treated by a similar process and had had no complaints. Their lordships' judgment was that the facts showed negligence in manufacture. According to the evidence, the process of manufacture was correct. The danger of excess of sulfites being left was recognized and guarded against. If they were left, some one was at fault. The appellant was not required to show who this was. Their lordships allowed the appeal with costs in all the courts. This probably means more than doubling the \$12,250 damages. The retailers as well as the manufacturer were made liable.

The Eradication of Rabies from England

Rabies was eradicated from England about forty years ago by an order for the compulsory muzzling of dogs for a period. This prevented communication of the disease by any dog that happened to be in the incubation stage. The effect has been maintained by the quarantine of all imported dogs for a time which exceeds the incubation period. Though rabies is prevalent on the continent of Europe, these measures have kept England free from it, with one limited exception. In 1918 an outbreak occurred in Devon and Cornwall owing to an infected dog having been smuggled into the country. It took three years to weed out this outbreak. Since 1921 there has been no confirmed case of rabies among the dogs of this country though since 1919 twelve cases have occurred in imported dogs while undergoing quarantine. The vigilance that is exercised with regard to the importation of dogs is shown by the recent case of a woman traveling from Berlin and landing at Croydon airport carrying a very small dog known as a German pinscher. The dog was placed in quarantine, but she was fined \$10 because she had not obeyed the regulation which requires any person bringing a dog to obtain a landing license. The maximum penalty for the offense is \$250, and she was let off with the much smaller fine because the magistrate was satisfied that she did not break the law deliberately. She knew that the dog would have to be quarantined and thought that this was all that was necessary.

Damages for Shock

The extent to which damages can be claimed for shock are surprising. It has been decided in the law courts that illness resulting from nervous shock may be the immediate consequence of a wrongful act and that there may be cause of action against the person responsible although he never could have expected such a result. The following is an example. A woman was told, by way of a practical joke, that her husband, who had been to some races, had had an accident and broken both his legs. She was asked to fetch him home in a carriage and to take some pillows with her. The shock of this fabrication caused a serious illness and she was awarded \$500 damages. It has even been decided that a person can claim damages for shock because he was the spectator of an accident. A woman was awarded \$50 for shock to her nerves which prevented her from performing her household duties, so that she had to employ outside help. The shock was caused by seeing an omnibus mount the curb and slightly injure a man. A few years ago the court of appeal ordered a new trial of an action in which a jury gave a verdict against a plaintiff who claimed damages for

shock One of the judges remarked that the branch of the law relating to shock had developed considerably in recent years A similar development has taken place with regard to the compensation of workmen for injury arising in or out of their employment A man became ill in consequence of being stung by an insect on his way to work He was awarded compensation for this as an injury arising out of his employment

Modernization of Hospital for Nervous Diseases

The National Hospital for Nervous Diseases, Queen Square, London, may be described as both the birthplace and the home of British neurology It was there that its great men—Hughlings Jackson, Ferrier, Gowers and others—worked It has 186 beds and also maintains a convalescent home of thirty-two beds at East Finchley Its activities have been hampered for several years because of lack of accommodations The modernization of the hospital and the provision of new buildings and equipment would cost \$900,000 The Rockefeller Foundation has offered \$600,000 on the condition that the remainder required for the improvements is raised within two years A further \$300,000 would be given by the Rockefeller Foundation as an endowment for research work at the hospital, which is claimed to be the leading center of the world for neurology Probably more neurologists have been trained there than at any other similar institution Men from all parts of the world, and particularly from America, come there for training

PARIS

Nov 8, 1935

Results of Compulsory Antidiphtheria Vaccination

An interesting report has just been published by Reh in the *Revue d'immunologie* on the results of the vaccination of school children at Geneva with the Ramon anatoxin In a population of 160,000 there are about 25,000 children attending the public schools Reh cites an instructive example of the value of such a method Three children of the same family, aged respectively 6 months, 3 years and 4 years were admitted to a crèche The youngest was placed in a ward of nonvaccinated infants the two others in wards in upper stories of the crèche, containing children of about their own age In spite of a negative certificate of having any contagious disease the three children were diphtheria carriers An epidemic of diphtheria followed the admission of the 6 months old infant to the ward of nonvaccinated infants of the same age All the nonvaccinated nurses in this ward also were victims In the other two wards, to which the 3 and 4 year old children had been admitted, the children had been previously vaccinated In spite of being in constant contact with the two carriers, these vaccinated children did not acquire the disease

From February 1929 to December 1934 a total of 11,150 school children have been vaccinated, 8,953 were given three and 1,436 two injections of the Ramon anatoxin The former received 15 and the latter 20 antigen units Postvaccinal reactions of mild local character occurred in 123 and a febrile reaction in 294 cases The results of the compulsory vaccination of school children in the canton of Geneva is evident by a comparison of the number of cases of diphtheria in that canton with the total number in all of the cantons of Switzerland

| | |
|------|--|
| 1929 | 286 in Geneva versus 3,723 for all Switzerland |
| 1930 | 131 in Geneva versus 4,545 for all Switzerland |
| 1931 | 130 in Geneva versus 2,641 for all Switzerland |
| 1932 | 133 in Geneva versus 2,265 for all Switzerland |
| 1933 | 80 in Geneva versus 2,271 for all Switzerland |
| 1934 | 25 in Geneva versus 1,775 for all Switzerland |

The decreased morbidity is especially applicable to children of school age, who constitute the majority of vaccinated per-

sons Sixty-four cases of diphtheria were observed at the schools of Geneva in 1931 forty-five in 1932, twenty-five in 1933 and only thirteen in 1934

The influence of vaccination on the death rate from diphtheria is even more striking Since 1929 there has not been a single death among vaccinated children Among the 11,150 vaccinated children there were fifty-one cases of diphtheria It is necessary, however, to exclude fifty children with nondiphtheritic sore throat, who were carriers but were reported as having diphtheria In children with a negative Schick reaction it is impossible to distinguish in vaccinated children between a true diphtheria and an ordinary sore throat developing in carriers The investigations of Dopfer (*Bull Acad de med* 112 801 [Dec 18] 1934) have made it possible from both an immunologic as well as clinical standpoint to confirm the existence of nonspecific sore throat in children with a negative Schick reaction but who are diphtheria bacillus carriers

Included in these fifty cases occurring in vaccinated children are three of rhinitis with rapid recovery and forty-seven pharyngitis cases, of which forty-three were of benign appearance, four with false membranes and only one with severe general symptoms All the forty-seven children recovered Evidently there was inadequate immunization in spite of three anatoxin injections in the four cases of false membrane.

Cancer of the Cervix After Subtotal Hysterectomy

Mme Simone Laborde and two of her assistants at the Cancer Institute of Paris reported their observations on the frequency of cancer of the cervix following subtotal hysterectomy at the July 1 meeting of the Gynecologic and Obstetric Society They studied 1,508 cancers of the uterus from 1921 to 1935, including 1,165 of the cervix, fourteen of the body, one sarcoma, 101 vaginal recurrences following complete hysterectomy for cancer, forty-four pelvic recurrences of various kinds, and fifty-seven cancers of the cervix after subtotal hysterectomy The percentage of the latter to those of cancer of the cervix in general is 4.9 One should not speak of cancer of the cervical stump following subtotal hysterectomy in cases in which such a cancer is only a stage in the development of a uterine cancer In other words, a relatively long period must have elapsed between the subtotal hysterectomy and the appearance of the cervical neoplasm

It has been customary to state that, if cancer appears within a year after the subtotal hysterectomy, it already existed at the time the operation was performed It is impossible to know the real condition of the cervix in women who do not present themselves for examination when the first symptoms are noticed Furthermore, certain endocervical cancers develop in such a latent manner that many months may elapse before they give rise to symptoms Delayed appearance does not always signify a "healthy interval" In the fifty-seven cases of cervical cancer after subtotal hysterectomy observed by Laborde, eighteen appeared "early," four without any "healthy interval" and fourteen after an interval of from one to six months The "late" cases appeared after an interval of from one to twenty years as follows three after one year, five after three years, five after four years, one after five years one after six years, two after seven years five after eight years, one after ten years two after eleven years, two after twelve years, one after fourteen years, four after seventeen years and two after twenty years These last two intervals are the longest ever reported Only thirty-nine, or 3.36 per cent, of the fifty-seven cases ought to be considered as true cancers of the cervix developing late enough after the subtotal hysterectomy, i. e. to be independent of an overlooked cancer at the time of operation The majority of cancers developing in the cervical stump develop from the vaginal epithelial covering When a glandular type is found,

one must always suspect that the lesion termed "fibroma" for which the subtotal operation was done in reality was a cancer of the body with extension into the cervix. This is especially true of the cases in which the cervical cancer appears without any "healthy interval." In spite of this suspicion, Laborde has encountered three "late" cases of the glandular type in women who had been operated on for fibroids two, three and four years, respectively, before. In such instances there must have been an independent development of cancer from the endocervical glands.

The prognosis of cancer developing in a cervical stump is not as favorable as that of cancer developing in the normal cervix, because invasion of the bladder and pelvic cellular tissue occurs relatively early. The treatment that has generally been employed at the Cancer Institute is radium, associated or not with high voltage roentgen therapy. Radium is difficult to use, because the fornices of the vagina are obliterated and the cervical canal is too short as a rule. Twenty of the fifty-seven patients were given radium treatment alone and thirty-two both radium and high voltage roentgen therapy. One patient has been cured for eleven years, one for seven years, and one for five years. Two others are in good condition after two and one after one year. All the others died within a year after being first examined, hence the prognosis is much less favorable than in cases of cervical cancer in which there has been no subtotal hysterectomy. As to development of a cancer in the vaginal scar following complete hysterectomy for noncancerous lesions only nine, or 0.68 per cent, such cases were observed by Laborde, in a total of 1,305 cancers of the uterus (1,165 cervical and 140 of the body).

Prof. Gustave Roussy Promoted in Legion of Honor

In the recent list of promotions of the minister of national education appears the name of Prof. Gustave Roussy, dean of the Faculty of Medicine of Paris and director of the anti-cancer center of the Paris region. Professor Roussy has rendered distinguished service to medicine in France and amply merits his promotion to be a commander in the Legion of Honor.

Fiftieth Anniversary of the German Gynecologic Society

In October the Deutsche Gesellschaft für Gynäkologie held a session in Munich to celebrate the fiftieth anniversary of its founding. After the society was founded in Strasbourg, which was then a German city, its first congress was held in Munich under the chairmanship of Professor von Winckel. The history of this society has been closely associated with the development of gynecology as a specialty. As Prof. A. Mayer of Tübingen, chairman of the society, in an article in the *Münchener medizinische Wochenschrift* wrote, the specialty of gynecology in Germany is an offshoot of "surgery," which was grafted on "obstetrics." This combination gave rise to certain difficulties in the development of the new specialty. Young obstetricians had to learn surgery, whereas in other countries experienced surgeons became gynecologists. The result was that "operative gynecology" in Germany was possibly inferior to that of some foreign countries, but this applies only to the first years of the new development. Gynecology therefore in its early years was characterized by a surgical trend. It sought to develop within the realm of so called greater gynecology. Soon "minor gynecology," so called, sprang up in opposition to greater or major gynecology. Minor gynecology became interested in the ills that affect woman and was not confined chiefly to the diseases of certain organs. After women ceased to con-

fine their activities to the home and the care of a family and had entered professional and industrial life, new problems arose for gynecology, and the connections with other closely related specialties became more numerous. The conception of gynecology as comprising the biology and pathology of womankind arose. From "frauenheilkunde," or the art and science of medicine as applied to women, there developed "frauenkunde," or the knowledge of womankind from a wide range of view. Thus, gynecology has developed from a specialty dealing chiefly with the diseases of the female organs into a specialty that embraces the whole personality of woman as an individual creation and a significant member of society.

Meeting of the German Lay Practitioners

The tendency under the present régime in Germany to promote the cause of the so-called *heilpraktiker*, or the nature cure practitioners, has been frequently mentioned in recent letters. The "Heilpraktikerbund Deutschlands, Reichsverband in München" held recently in Frankfurt-on-Main a session to which all the district leaders of the reich and the directors of the professional schools of the league were invited. About 200 representatives attended. This league was created in 1933 by the federal ministry of the interior and was assigned the task of cleansing the league, which consisted of twenty-three former associations of *heilpraktiker* and numbered 5,700 members, of all unsavory elements. The league is endeavoring to perform the task assigned to it and, it is asserted, has launched a bitter fight against quackery. From 1,500 to 2,000 former *heilpraktiker* have already been eliminated, and the management of the league has stated that about 1,500 more members will be removed. Those members thus eliminated are for the most part *heilpraktiker* who have refused to appear before a commission of the aforementioned league and submit to an examination as to their knowledge of the theory and practice of the principles of healing advocated by the league. To what extent these *heilpraktiker* differ from quacks, in a scientific and medical sense, is not clear. In any event, the opposition of licensed physicians to these lay practitioners is great. On the other hand, the *heilpraktiker* are endeavoring to do all in their power to prove to the government authorities, who are well disposed toward them, the serious nature of their activities. It is of interest that the director of the league, a government appointee, spoke at this meeting on "The Interests of the Heilpraktiker Profession," the director of the federal professional school of the league discussed the continuation courses to be given next winter, and the leader of the press and propaganda presented the aims and tasks of the propaganda of the league. It is evident that the *heilpraktiker* will exert themselves to the utmost to gain the same rank and prestige enjoyed by regularly licensed physicians.

The Value of Revaccination Against Smallpox

Dr. Breger of the federal bureau of health has given an opinion on the value of revaccination against smallpox, which was presented by the president of the federal bureau of health at the session of the international bureau of health, held in Paris in May 1935. This question has again come to the fore because the director of the vaccination service in the region of Rio de Janeiro recently expressed the view that a single vaccination confers a lifelong immunity against smallpox and that a reduction of immunity is so rare that it is of no practical importance, revaccination, he contended, has no value and is superfluous. He asserted further that the many good results from revaccination reported in German statistics are for the most part immunity reactions that have been erroneously considered as evidence of successful revaccination. In view of these facts, revaccination in Rio de Janeiro had been almost entirely given up and no untoward conditions had resulted.

Dr Breger stated that German experience over a long period of years went to show that a single vaccination in childhood does not suffice to protect a population against a smallpox epidemic. As an illustration he cited the fact that in Bavaria the vaccination of children was introduced in 1807 but did not eradicate smallpox from that region. However, after the federal vaccination law went into effect in 1874, which prescribed revaccination, deaths from smallpox (aside from the first few years after the law went into effect) have rarely occurred. Practical experience has therefore shown that the primary vaccination is not sufficient and that a renewal of immunity through revaccination is needed if an effective protection against the spread of smallpox epidemic is to be secured. This example can be confirmed by numerous observations during more recent years in Czechoslovakia, Hungary, Rumania, Poland, Latvia, Soviet Russia and other countries.

The duration of vaccination immunity has been placed by an English commission at from nine to ten years on an average. It was the opinion of this commission that vaccination immunity must be renewed from time to time in order to reach the highest degree of protection. The German vaccination commission reached the same conclusion, it also recommended a revaccination ten years after the first vaccination. The most convincing documentary evidence for the duration of vaccination immunity is furnished by the English smallpox statistics of the previous decade, because, owing to the peculiar nature of the English vaccination service, different groups of the population may be distinguished with respect to vaccination. In 1926, for example, younger persons, following a single vaccination, developed smallpox after twelve years at the earliest. In revaccinated persons it was found that in the 1-30 years group only one case of smallpox developed, and that was in a person aged 15. It appeared that after about ten years from the date of the first vaccination and after about twenty years from the revaccination a sure immunity was no longer present. It is evident, therefore, that a lifelong vaccination immunity does not exist. England's experience is in harmony with numerous observations made in Germany. Following an epidemic of smallpox in 1917, it was ascertained that 79 per cent of all deaths from smallpox concerned persons who had passed their fortieth year. Strictly speaking, a revaccination should therefore be applied every ten years. Since that is not feasible, emergency vaccinations are given in the event of a smallpox outbreak. In Germany the reaction following revaccination is termed positive if nodules or vesication appears at the site of the vaccinal incision, this is not however, solely an immunity reaction. On the basis of epidemiologic observations, it appears advisable to hold fast to revaccination as the backbone of smallpox vaccination.

Control in the Bandage Trade

Between the organization of the German pharmacists and of the manufacturers of bandage supplies an agreement has been reached that is designed to insure to pharmacies an adequate supply of suitable bandages needed by the *kranken-kassen* including the special packages intended for the use of puerperants. A special committee will test the products of the bandage manufacturers as to quality and priceworthiness. If the products of which samples are furnished to the testing commission meet the requirements, the manufacturer of bandage supplies is entitled to furnish to the pharmacies his products in an accepted package. Every package must bear the emblem of the *Deutsche Apothekerschaft* together with the mark of the federal guild of the manufacturers of bandage supplies, a stamp showing the contents (quality and weight) the key number of the dealer and finally, this "Notice. Tested as to quality and priceworthiness by the *Deutsche Apothekerschaft* and the *Reichsfachschaft der Verbandsmittelhersteller*

BELGIUM

(From Our Regular Correspondent)

Oct. 29, 1935

First International Congress of Gastro-Enterology

The first International Congress of Gastro Enterology was held in Brussels under the chairmanship of Dr Jean Schoemaeker of The Hague. Bringing together for the first time the internists, surgeons, radiologists and biochemists, whose researches dealt chiefly with the pathology of the digestive tract, it was a complete success. Twenty-three countries were represented. While the congress was in session, the officers of the congress, united in a general assembly with the delegates of twenty one nations, laid the foundations for an international society of gastro-enterology, which, after the manner of the International Society of Surgery, will constitute a closed group.

GASTRITIS

The etiology, symptoms, diagnosis, treatment, radiologic aspects and pathology of gastritis were discussed. Konjetzny pointed out that the question of the indications for the surgical treatment of gastritis is far from being solved. In acute gastroduodenitis, with or without erosion, internal treatment is indicated. At present the diagnosis may be established with certainty. In chronic gastritis the indications for gastric resection are partially established. The radical operation is necessary for (1) circumscribed hypertrophies of the areolar or polypous mucosa, in which the presence of cancer may be chemically suspected and (2) various forms of hypertrophic stenosis of the pylorus, a disorder that is, in most cases, the result of a chronic gastritis. It need occasion no surprise if the results of a gastric resection are unsatisfactory, owing to an acute or subacute gastroduodenitis.

ULCERATIVE COLITIS OF NONAMEBIC ORIGIN

Donati described the treatment to be followed in grave ulcerative colitis of nonamebic origin. The condition, while resistant to medical treatment, is susceptible of surgical intervention, if applied early. Surgical treatment is indicated also in the various complications and sequels of colitis. Two kinds of intervention are to be considered: (1) indirect for the eradication of foci assumed to be or shown to be the cause of the colitis, such foci may involve the mouth and the teeth, the stomach and the duodenum, the appendix, the colon, the rectum, the peritoneum, the gallbladder, the uterus and the adnexa, and the urinary organs, and (2) direct, on the colon itself. These interventions may take on different forms: (a) enterostomy, intestinal fistula to effect lavage of the colon, or artificial anus for the total exclusion of the diseased intestine and the withdrawal of fecal matter, (b) anastomosis and intestinal exclusion, ileosigmoidostomy, ileotransversotomy, typhlosigmoidostomy, and (c) resection of the colon (partial colectomy), total colectomy is inadmissible. The operative technic does not involve any special rules, the indications are the most important problem.

Training of African Natives as Medical Aids

The colonial administration of the Belgian Congo has undertaken to create schools in which the natives may be trained as aids to nurses, aids to midwives, "sanitary guards" and nurses.

The program as announced shows how much thought has been given to the organization of this work, and excellent results from these efforts may be anticipated. The program of instruction for the aids to nurses which requires the least preparation may be outlined as follows:

Points covered by the theoretical course: (1) moral responsibilities and duties of a nurse's aid, explanation of laws and regulations concerning medical service, (2) preparation of brief case reports based on cards and bulletins in current use in the

hospitals and dispensaries and in traveling services in vogue in Africa, (3) microscopy as applied to tropical pathology, (4) practical ideas on hygiene as applied to the ward services of a hospital, to dispensary services, and to centers of treatment, individual hygiene, hygiene of villages, work-camps and work-yards, ideas concerning contagion and prophylaxis, (5) care and use of the equipment of wards, dispensaries, centers of treatment and traveling services, ideas concerning cleanliness, asepsis and antiseptics, scales, weights and measures, and (6) ideas concerning the principal disorders treated in traveling services and on the more important tropical endemic diseases, preparation of solutions, and instruction in the use of specific drugs

Points covered by the practical course (1) rendering of aid in hospital services, in consultation centers, in the dispensary and in the centers of treatment, (2) microscopy, (3) transport of patients and wounded persons, first aid in emergency cases, management of stretcher service, (4) dressings, and (5) minor operations and interventions in hospital and in traveling services

Prof Léon Frédéricq

In the death of Prof Leon Frédéricq, whose career covered more than half a century in experimental physiology, Belgium has suffered a severe loss. Born in Ghent in 1851, Leon Frédéricq completed in that city his doctorate in the natural sciences and in medicine in 1871. After working in several laboratories in foreign countries, he served as an assistant in physiology and comparative anatomy at the University of Ghent. During this period he proved the existence of fibrinogen in the blood plasma. Later, when Schwann, eminent proponent of the cellular theory, was casting about for some one for the chair of physiology at the University of Liege, his choice was Leon Frédéricq, then 30 years old. From 1879 on, for forty years, Leon Frédéricq distinguished himself by his clear and concise presentation, which drew about him young collaborators who shared their teacher's enthusiasm for laboratory research. In this favorable atmosphere he founded what amounted to a school of biology, whereby he gave a transcendent impetus to the experimental sciences and became one of the leading physiologists of his time. His researches dealt chiefly with the physiology of the circulation, respiration and the nervous system. He demonstrated that the respiratory movements are dependent on a medullary center the action of which is conditioned by the carbon dioxide content of the human blood. In 1928 he was chosen president of the Academy of Medicine.

Intussusception in Infants

In a recent issue of *Rozhledy v chirurgii a gynaekologii* (1935, No 3, p 340) Polák made a report on fourteen cases in which the diagnosis of intestinal invagination was made. In twelve cases the diagnosis was confirmed. Surgical treatment was employed in eleven of these cases and one was cured without operation. Three patients who were operated on did not recover. The others did, and the condition did not recur. In two cases the diagnosis was not confirmed by the operation. Early diagnosis is necessary for the success of any therapy. Ombrédanne's law is valid for nearly all cases. Blood in the discharges as well as a palpable tumor occurs, however, only in advanced stages of the illness. The earliest and most frequent signs of intussusception are sudden abdominal pains of intermittent character with vomiting. This must always arouse suspicion of invagination, even if other symptoms are missing. As, however, diagnosis based merely on these symptoms can never be complete and justify surgical treatment, one should in these early stages make a roentgen examination immediately

and try medical treatment, operating only if this should fail. In cases in which hemorrhage has occurred and there is a tangible tumor, the diagnosis is usually clear and a roentgenogram is unnecessary, immediate operation being called for. Operation is done under ether anesthesia through a pararectus or by a middle abdominal incision above the navel. Spinal anesthesia also is recommended. Disinvagination is most frequently effected by expression of the intussusceptum, a careful pull on the invaginated bowel being sometimes necessary. To prevent recurrence, Ombrédanne's ileoceceopexy was used several times, but for cases that have a tendency to recur, the method of Coubine and Steimclenger is recommended, it consists in the suture of the serosa of part of the ileum to the cecum. Should disinvagination be too difficult, Brown's operative method is recommended, consisting in incision of the neck of the invagination, disinvagination and suture of the enterostomic wound. If gangrene has occurred, Maunsell's operation is preferred to resection of the invagination, which is too severe for infants.

Surgical Complications of Diabetes and Treatment

Siska (p 362) reports on the results of treatment of 105 cases of surgical diabetes. The death rate was 18.09 per cent. The author believes that surgical complications of diabetes occur less frequently in women than in men. Five of these patients suffered from furunculosis, thirty-eight from abscess and carbuncles, and twenty-nine from gangrene of the limbs. In thirty-four cases, diabetes complicated other diseases, such as acute and chronic appendicitis, incarcerated hernia, varices, hemorrhoids and fractures. Much stress is laid on preparation of the patient before the operation as well as on good nursing. Great importance is attached to the collaboration of the internist, on whose instructions the result of the operation often depends. Various modes of anesthesia are discussed. Intermittent anesthesia with ethyl chloride is regarded as most suitable, the acidity after the operation being thus considerably reduced, in addition, the patient is spared the psychic shock.

Operation for Pancreatic Cysts

In the same issue Rolak and Gjurić describe a case of pancreatic cyst, which developed after resection of the stomach according to the method of Pean and Rydiger, probably as a result of the ligation of a pancreatic duct during operation. After the marsupialization of the cyst a fistula developed, which resisted treatment for three years. The cyst contained all three pancreatic ferments. Comparison of the pancreatic secretion in the duodenum and in the fistula, and the effect of different food on the pancreatic secretion, showed that secretion was stimulated most by hydrocarbon, then came ether, fat and albumin. Milk had the least effect. As the fistula did not close, a pancreatogastrostomy was performed according to Jedlicka's technic. The literature describes various modifications of this treatment of pancreatic cysts used in about twelve cases with good results.

Professor Fiessinger's Lecture

Prof Dr Noel Fiessinger of Paris lectured in Prague November 4, on parenchymatosis during cirrhosis of the liver. If the liver, kidney or another organ is the site of a chronic inflammation, there first appear the destruction of the parenchyma and a sclerosis of the mesenchyme. Professor Fiessinger discussed the relation of mesenchymatosis and parenchymatosis during the illness. Clinically only the total aspect of their action is observed. The physician has to analyze the case to find what may be repairable and which symptoms result from the parenchymatous degeneration. The curing of a sclerotic organ does not mean the curing of the sclerotic tissue. Sclerosis is due to a scar and it cannot be cured. Besides the scar the physician has to keep in mind the reaction of the organ, or what Professor Fiessinger calls "secondaire."

Deaths

During the last two months, Czechoslovakian medicine has lost three leading personalities

Prof Dr Anthony Hanák, aged 46, chief of the physiologic institute of Carl's University in Prague, died September 12. Professor Hanak studied the hemodynamic effects of absorption and secretion of capillary walls, completely overthrowing the Pflüger dogma. For a year he studied hematology in Barcroft's laboratory in Cambridge. In 1925 he organized the physiologic institute in Bratislava, and since 1930 he had been chief of the physiologic institute in Prague.

October 1, Prof Dr Charles Vymola, chief of the laryngologic and otologic department of the policlinic in Prague, died at the age of 72.

On the eve of his fiftieth birthday, Dr Prochazka, professor of neurology and psychiatry of Masaryk's University in Brno, was shot by a former patient. He was very popular and was president of the Moravian Medical Chamber (Association).

Electrocardiographic Changes in Myocardial Infarct

Dr Jairo Ramos, in a lecture before the Associação Paulista de Medicina, discussed the electrocardiographic changes due to myocardial infarct. He reviewed the experiments of Smith, in which the electrocardiographic changes found in myocardial infarct were interpreted like those caused by ligation of the coronary branches. The diagnosis of myocardial infarct by the electrocardiogram was first made in 1918 by Pardee and was based on Smith's work. The speaker illustrated his lecture by showing a collection of electrocardiograms.

Serum Albumin and Blood Globulin in Liver Diseases

Dr João Manoel Rossi, in a lecture before the Associação Paulista de Medicina, discussed the role of the liver in the formation of blood proteins, especially serum albumin and globulin. Blood proteins, according to the speaker, are formed by the liver. Experiments proved that blood proteins are well regenerated in animals with normal liver functions, slowly regenerated in animals with a slight injury of the liver due to the administration of chloroform, and not regenerated at all after hepatectomy. The speaker wondered whether the determination of the serum albumin and globulins in the blood could be a test for liver insufficiency. From observations in 100 cases he reached the following conclusions: The content of serum albumin and globulin in the blood, alone, is not of diagnostic and prognostic value. The serum albumin-globulin ratio cannot be considered as a test for liver insufficiency. However, it is of great prognostic value for the general condition of the patient not only in liver diseases but in several other diseases. The progressive falling of the coefficient, on the one hand, indicates that the patient is near death. Its increase on the other, indicates an open improvement of the patient toward recovery.

Methylene Blue in the Treatment of Leprosy

Dr Renato Braga, in a lecture recently delivered before the Sociedade Paulista de Leprologia, claimed priority in the administration of methylene blue in the treatment of leprosy, which he used earlier than did Dr Feliz Guisard. He treated lepers, in the Asilo Colonia St. Angelo and in Taubate, with methylene blue, associated with chaulmoogra oil in 1916. He treated 122 lepers with methylene blue according to Montel's technique, that is, injections of increasing doses of from 10 to 45 cc of a 1 per cent solution of methylene blue in doubly distilled water. In some cases the results were better than those obtained by the chaulmoogra oil treatment. The speaker

advised the use of methylene blue in the diagnosis of leprosy, leprotic lesions, even when only slightly visible, are colored by the stain. He reported satisfactory results from the administration of methylene blue, associated with sodium salicylate, in the treatment of leprosy of the painful form and discussed the results of intra-arterial injections of methylene blue in leprosy of the atrophic and ulcerous form.

Pan-American Conference of Mental Hygiene

The first Pan-American Conference on Mental Hygiene will be held in the near future in Rio de Janeiro under the auspices of Brazil and with the collaboration of some other South American countries. It is hoped that all countries in North, Central and South America will send delegations. The following topics will be discussed: social and hospital care of neuropsychiatric patients, prevention of organic diseases of the nervous system, prevention of alcoholism, forensic psychopathology and psychology, prevention of delinquency, psychoanalysis, psychotechnic and mental hygiene in work, mental hygiene and education, sexology in mental hygiene, organization and propaganda of mental hygiene, eugenics.

A Solarium at the Extreme North

The arctic department of the Leningrad Institute of Physical Therapy studied this year the influence of the arctic climate on man. On the Imandra shore of lake Imandra (latitude 67° 41') an aerosolarium was established, which provided more than 1,000 sun and air baths. Next year there will be built a special enclosed solarium for air baths. Preliminary studies indicate that aeroheliotherapy in extremely northern latitudes has great curative value because of the marked biologic activity of the northern air and sun. For this purpose the institute plans to build sanatoriums and health resorts in many districts of the Kola peninsula.

The Health Resort Conference

The seventh All-Union Conference of Health Resorts and Spas will be held in Moscow, December 25. The previous conference was called eight years ago. The subjects for discussion at the conference will be Health Resorts of the Soviet Union, Curative Gaseous Spas and Treatment of Children's Diseases at Health Resorts, a scientific exhibit will show the natural resources of Russian health resorts.

Ultra Short Wave Therapy

The All-Union Institute of Experimental Medicine is studying ultra short wave therapy. The greatest difficulties in this problem are the dosage of the waves and correct indications for their use. It is not accurately known what quantity of the energy produced is utilized by the organism under treatment. Ultra short waves produce a vasoconstriction. They are effective therefore only when the blood vessels have not lost their ability to contract because of organic changes such as those that cause gangrene. The ultra short waves have a bactericidal action and thus promote simultaneously the immune properties of the organism. They are effective in the treatment of furunculosis, carbuncles and other local and general inflammations. Even peritonitis of gynecologic origin, in its most acute stages, responds to this method of treatment.

The warmth effect of ultra short waves is used for the treatment of neuritis and neuralgia. The waves were found beneficial in chronic neurodermatitis with cutaneous itching, which ceased after irradiation of certain parts of the central nervous system and not of the itching part. However, it is too soon to use ultra short radio wave generators because possible

dangers must be studied in laboratories and scientific institutes, and the medical and technical staffs must be instructed in their use.

Prof Michael P Tuchnov

Prof Michael P Tuchnov died in Moscow, September 19, at the age of 56, from angina pectoris. As the result of his scientific work on immunology, he was elected professor of pathologic physiology at Kazan. In 1930 he went to Leningrad and Moscow, where he worked in the All-Union Agricultural Academy, in the Kremlin's Laboratories and in other scientific establishments. In his thirty-three years of scientific activity, Professor Tuchnov made investigations also in the fields of bacteriology and biology.

The Aspirant Groups

The increasing number of medical schools and the necessity for highly specialized scientists has led the People's Commissariat for Health to consider the question of organizing aspirant groups in medical institutes. Physicians up to 35 years of age can be enrolled in the aspirant group after they pass examinations in special medical courses, foreign languages and the natural sciences. This course of study is for a three-year period. The first year and a half is devoted to theoretical science related to the specialty taken at the institute. After examinations in practical and theoretical courses, the aspirants pass the second one and one-half years in clinical study. After his thesis has been accepted, the aspirant receives the degree of medical science candidate, if the Supreme Qualification Committee of the People's Commissariat of Health approves him. The Aspirant Institute must help to supplement deficiencies in highly qualified specialists. After graduation their number in the different medical specialties will be markedly increased.

New Ambulatorium in Moscow

In October a new polyclinic for workers in heavy industry was opened in Moscow. It is situated in a building specially reconstructed to serve 2,000 patients a day. The walls of the x-ray room are covered with lead packing. This polyclinic is one of the best Moscow ambulatoriums, and the most famous specialists receive patients there.

Marriages

JOHN C ADAMS, Surg. Lieut. Commander, U. S. Navy to Miss Lucene Prestwood, both of Pensacola, Fla., September 17.

HENRY TOMPKINS KIRBY-SMITH, Sewanee, Tenn., to Miss Mary Phillips Woolvorton of Birmingham, Ala., September 21.

HAROLD L. BRERETON, Emmetsburg, Iowa, to Miss Margaretta Williamson of Washington, D. C., in Chicago, October 16.

ORLANDO BENEDICT MAYER to Miss Nancy Phillips, both of Columbia, S. C., at Blowing Rock, N. C., September 11.

MAXWELL G. SIMPSON, Elizabeth, N. J., to Mrs. Lillian Haver Miller of Southern Pines, N. C., September 12.

CHARLES SUMMERS STEVENSON, Baltimore, to Miss Alice de Guildry Stevens of New Haven, Conn., September 21.

HENRIK MARINUS ROZENDAAL, Rochester, Minn., to Miss Katherine Scranton of Scranton, Pa., October 19.

PATRICK H. W. MURPHY, Jersey City, N. J., to Miss Marion B. Breen of Douglas, Ont., Canada, August 14.

CLARENCE LEE GUYTON JR., Monroe, N. C., to Miss Jennie Llewellyn Finlayson in Cheraw, October 26.

NICHOLAS GOTTEN, Philadelphia, to Miss Mary Meredith Whittaker of Memphis, Tenn., November 6.

HARRY P. BLABER JR., Toi Shan, China, to Miss Constance White of Naugatuck, Conn., November 27.

FRANK TRUMBO HARPER, Jamestown, N. C., to Miss Gladys Virginia Duval of Greenville, September 3.

JETHRO MERIVETHER HURT to Miss Margaret Virginia Bennett, both of Blackstone, Va., November 6.

RALPH JORDAN MITCHELL, San Francisco, to Miss Olga Verlaque of Lexington, Ky., in October.

GEORGE O. A. KELLOGG to Miss Emma D. Jensma, both of Nampa, Idaho, in Boise, September 27.

CLARENCE HUNT WHITE, Burnsville, N. C., to Miss Mary Young Hunt of Henderson, October 24.

WILLIAM A. DOWER, Windsor, Conn., to Miss Mary G. Church of West Hartford, October 14.

HILLIS LEDBETTER SEAY, Sanatorium, N. C., to Miss Margaret Vanstory of Lincolnton, September 2.

ERNEST H. DENGLE, Pottstown, Pa., to Miss Irma Arleen Greenawalt of Reading, November 2.

VACLAV GEORGE DVORAK, Chicago, to Dr. ELLA HELEN VALENTA of Cicero, Ill., October 30.

JOHN F. JUDGE to Miss Helen Englehart, both of Newark, N. J., in East Orange, November 8.

HARRY G. HUDNALL to Miss Elizabeth Beaufort Revercomb both of Covington, Va., October 5.

LEWIS W. CELLIO, Youngstown, Ohio, to Miss Dorothy Dowling of St. Louis, October 26.

RAYBURN NELSON JOYNER to Miss Olive Marie Rigdon, both of Jacksonville, Fla., November 7.

PAUL F. WILLWERTH to Miss Margaret Mathews, both of Binghamton, N. Y., September 5.

HAROLD A. FLETCHER, San Francisco, to Mrs. Virgil M. Hillyer at Baltimore, October 25.

EDWIN E. DAY to Miss Gertrude Douglas, both of Vancouver, B. C., Canada, October 5.

WILLIAM GROSSMANN JR., Richmond, Va., to Miss Virginia Cox of Lynchburg, November 3.

JOHN LINCOLN HOWETH, Jersey City, N. J., to Miss Edith Sloane Tompkins, September 28.

BOYD HARDEN, Pittsburgh, to Miss Ruth Elizabeth Holmes of McKeesport, Pa., October 26.

LOUTEN RHODES HEDGPETH, Lumberton, N. C., to Miss Louise Hogan of Hamlet, November 7.

FRANKLIN LEDGERWOOD GEIGER to Miss Beatrice Ott, both of Columbia, S. C., September 23.

GRACE M. JORDAN to Mr. Earl Scranton Duvall, both of Columbus, Ohio, November 9.

CECIL A. ROBINSON to Dr. LILA ROSE ROBERSON, both of Gladewater, Texas, October 6.

EDWARD O. GUERRANT, Winchester, Ky., to Miss Julia Bullard of Anniston, Ala., October 15.

PAUL R. MAULDEN, Kannapolis, N. C., to Miss Julia Watson of Greensboro, September 18.

CLAUDE MERRILL LEISTER to Miss Mary S. Butz, both of Allentown, Pa., November 9.

ROBERT H. CROW, Woodruff, S. C., to Miss Juanita Gregory of Spartanburg, November 4.

THOMAS STANLEY MEADE to Miss Mary Belle Long, both of Richmond, Va., November 7.

LOUIS EARL WHARTON to Miss Mabelle Lorenz, both of Akron, Ohio, November 2.

EDWARD DE WITT COOK, Buffalo, to Miss Emily Smith of Montclair, N. J., October 5.

WILLIAM E. ELKIN, Atlanta, Ga., to Miss Nell Osborne of Louisville, Ky., October 22.

WILLIAM E. E. TYSON to Mrs. Charles Franklin Patterson, both of Detroit, October 7.

PAUL JONES CHAMBERS to Miss Mary Ellen Watts, both of Charlotte, N. C., recently.

JOHN A. BOONE, Boston, to Miss Ellen Gleason of Bedford County, Va., October 19.

ALBERT S. HARDEN JR., Maplewood, N. J., to Miss Helen Baer Cox, October 12.

REUBEN J. GUEST, Fort Payne, Ala., to Miss Janie Chapman of Tuscaloosa, recently.

DAVID E. JONES, Indianapolis, to Miss Dorothea Barnett of Winamac, October 6.

DAVID MERRILL WEEKS to Miss Ruth Gould, both of New York, September 21.

CHARLES H. FARMER to Mrs. Eugenia Spivey, both of Macon, Ga., in September.

HOWARD CHARLES CLARK to Miss Vera May, both of Wichita, Kan., October 5.

JOSEPH CARL BAIER, Williamsport, Pa., to Miss Lois Winters, October 26.

Deaths

Charles Louis Mix, Americus, Ga., Harvard University Medical School, Boston, 1894, member of the House of Delegates of the American Medical Association, 1906-1907, past president of the Chicago Neurological Society, professor emeritus since 1929 and from 1920 to 1929 professor of medicine and head of the department, Loyola University School of Medicine Chicago, professor of anatomy, Northwestern University Woman's Medical School in 1899 and the dental school in 1901, assistant professor of anatomy, 1900-1903, professor of physical diagnosis, 1903 to 1914, and clinical professor of medicine from 1914 to 1920, Northwestern University Medical School, served during the World War, lieutenant colonel in the medical reserve corps from 1919 to 1929, for many years on the staff of the Mercy Hospital, Chicago, and consulting internist to the Illinois Central Railroad Company, was associated with Dr. John B. Murphy in editing *Surgical Clinics of North America* and was editor-in-chief of the *Practical Medical Series*, aged 65, died, November 21, of pneumonia.

John Leonard Eckel ♂ Buffalo, University of Buffalo School of Medicine, 1907, chairman of the Section on Nervous and Mental Diseases of the American Medical Association 1928-1929, associate professor of neurology and assistant professor of psychiatry at his alma mater, member of the American Neurological Association, the American Psychiatric Association, the Association for Research in Nervous and Mental Disease and the Central Neuropsychiatric Association, served on the medical advisory board during the World War, attending and consulting neurologist to the J. N. Adam Memorial Hospital, Perysburg, Buffalo General Hospital, Millard Fillmore Hospital, Memorial Hospital, Mercy Hospital, Our Lady of Victory Hospital, Sisters Hospital and the Providence Retreat, author of many articles on research published in medical journals, aged 55, died, November 26, of coronary occlusion and myocarditis.

Raymond J. Wenker, Milwaukee, Marquette University School of Medicine, Milwaukee, 1914, also a dentist, member of the Associated Anesthetists of the United States and Canada, formerly professor of dental anatomy and operative technique, professor of orthodontia and instructor of orthodontia technique, professor of oral surgery and temporary dean, Milwaukee Medical College Dental Department, professor of oral surgery, orthodontia, dental anatomy and operative technique and dean, College of Wisconsin Physicians and Surgeons Dental Department, assistant in nose and throat clinic at his alma mater and professor of orthodontia and associate professor of oral surgery at the Marquette University Dental Department, aged 67, died, October 24, of coronary thrombosis, arteriosclerosis and hypertension.

Herbert Francis Twitchell, Portland, Maine, Medical School of Maine, Portland, 1883, past president and member of the Maine Medical Association, past president of the Cumberland County Medical Society, at one time instructor in clinical surgery at his alma mater, fellow of the American College of Surgeons, consultant to the Maine Eye and Ear Infirmary, Maine General Hospital and the Children's Hospital Portland, the Webber Hospital Biddeford, and the Bath (Maine) City Hospital, aged 76, died, November 24, of cerebral hemorrhage and arteriosclerosis.

L. Rosa Hirschmann Gantt ♂ Spartanburg, S. C., Medical College of the State of South Carolina, Charleston, 1901, past president of the Medical Women's National Association, medical examiner of a draft board during the World War, member of the district advisory board, acting surgeon of the U. S. Public Health Service, at various times on the staff of St. Luke's Hospital, Trion and the Spartanburg General Hospital, aged 59, died, November 16, in a hospital at Philadelphia, of embolism following an abdominal operation.

Charles Daniel Fox, Ardmore, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1903, Medico-Chirurgical College of Philadelphia, 1906, served during the World War, at one time demonstrator of neurohistology and neuropathology, instructor in neurology and pediatrics, Hahnemann Medical College and Hospital of Philadelphia, formerly on the staff of the Children's Homeopathic Hospital, aged 55, died, October 24, of carcinoma of the liver and lung.

Frederick Bush Willard, Buffalo, University of Buffalo School of Medicine, 1890, member of the Medical Society of the State of New York, at one time instructor in anatomy at his alma mater, served during the World War, formerly

medical sanitary inspector with the board of health, aged 72, died, November 7, in the Buffalo City Hospital, of cerebral arteriosclerosis, cerebral hemorrhage and bronchopneumonia.

Leonard Wheeler, Worcester, Mass., Harvard University Medical School, Boston, 1870, member and former vice president of the Massachusetts Medical Society, trustee, past president of the board and formerly on the staff of the Memorial Hospital at one time trustee of the State Hospital, Foxboro, at various times on the staffs of the City Hospital and St. Vincent Hospital, aged 90, died, October 2, of pneumonia.

Arthur Rowley Reynolds ♂ Chicago, Bellevue Hospital Medical College, New York, 1876, health commissioner of Chicago from 1893 to 1895 and again from 1897 to 1905, in 1911 named a lieutenant and in 1917 a captain in the medical reserve corps of the army, aged 81, died, November 14, in the Augustana Hospital, of injuries received when he was struck by an automobile.

Eugene Robert Van Meter, Springfield, Mo., Washington University School of Medicine, St. Louis, 1905, member of the Missouri State Medical Association, formerly assistant in clinical laryngology and rhinology at his alma mater, served during the World War, aged 52, died, September 30, in St. John's Hospital, of fat embolism, following a fracture of both legs.

William Francis Metcalf, Bayfield, Ont., Canada, University of Michigan Department of Medicine and Surgery, Ann Arbor 1888, fellow of the American College of Surgeons, formerly clinical professor of gynecology, Detroit College of Medicine, at one time on the staff of the Harper Hospital, Detroit, aged 71, died, October 17.

Olaf Severin Leedahl, Stanley, N. D., Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1907, member of the North Dakota State Medical Association, county coroner, formerly county health officer, aged 54, died, October 28, of carcinoma of the stomach.

August Angelo Cavagnaro, Stockton, Calif., Keokuk Medical College, College of Physicians and Surgeons, 1908, also a pharmacist, formerly city health officer and member of the state legislature, aged 59, died suddenly, October 15, of acute dilatation of the heart and chronic nephritis.

Hubert Schoonmaker ♂ Clifton Springs, N. Y., University of the City of New York Medical Department, 1891, fellow of the American College of Physicians, at one time superintendent of the Clifton Springs Sanitarium and Clinic, aged 72, died, October 21, of carcinoma of the lung.

George Collister, Boise, Idaho, Homeopathic Hospital College, Cleveland, 1880, member of the Idaho State Medical Association, on the staffs of St. Luke's and St. Alphonsus hospitals, formerly member of the city council, and city and county physician, aged 79, died, October 18.

Charles Edmund Fisher, Toledo, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895, fellow of the American College of Surgeons, for many years on the staff of St. Vincent's Hospital, aged 67, died, October 19, of coronary thrombosis.

Robert Hugh Campbell ♂ Vader, Wash., College of Physicians and Surgeons, Boston, 1906, past president of the Lewis County Medical Society, formerly member of the school board and bank president, aged 65, died, October 20, as the result of a cerebral hemorrhage.

Oscar E. Underwood, Roseboro, N. C., University College of Medicine, Richmond, 1909, member of the Medical Society of the State of North Carolina, aged 50, died, September 15, in the Highsmith Hospital, Fayetteville, of diabetes mellitus and carcinoma of the stomach.

James E. McGillicuddy ♂ Lansing, Mich., Detroit College of Medicine, 1898, past president of the Ingham County Medical Society, on the staffs of St. Lawrence Hospital and the Edward W. Sparrow Hospital, aged 63, died, October 17, of bronchopneumonia.

Joseph Herbert Ackerman, Asbury Park, N. J., Hahnemann Medical College and Hospital of Philadelphia, 1899, member of the Medical Society of New Jersey, on the staff of the Fitkin Memorial Hospital, Neptune, aged 65, died, November 2.

Roderic Stephen Elliott, Waupaca, Wis., Milwaukee Medical College, 1900, member of the State Medical Society of Wisconsin, served during the World War, aged 60, died suddenly, October 19, in Fort Francis, Ont., Canada, of heart disease.

James Jerome Parsons ♂ Monrovia, Calif., Syracuse University College of Medicine, 1913, member of the Associated

Anesthetists of the United States and Canada, served with the British army during the World War, aged 51, died in October

Paul Hardtmayer Walter, Bethlehem, Pa., Jefferson Medical College of Philadelphia, 1913, member of the Medical Society of the State of Pennsylvania, aged 48, was killed, November 16, when his automobile collided with a trolley car

Peter Lansing Wheeler, San Francisco College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1866, aged 91, died, October 2, in the Merritt Hospital, Oakland, of pneumonia, as the result of a fall

Benjamin W Brown ♂ Charlotte, N C, University of Virginia Department of Medicine, Charlottesville, 1886, senior surgeon in the U S Public Health Service, aged 74, died, October 25 of carcinoma of the prostate

Alice Hamilton Ward, Bloomfield N J, Woman's Medical College of the New York Infirmary for Women and Children, 1890, aged 70, died, November 15, in the Community Hospital, Montclair, of heart disease

Joseph Charles Buckley, Bay St Louis, Miss Tulane University of Louisiana Medical Department New Orleans 1910 served during the World War, aged 47, died, October 27, of cerebral hemorrhage.

Jean Baptiste Masse, Lawrence, Mass., School of Medicine and Surgery of Montreal Que Canada, 1902, member of the Massachusetts Medical Society, aged 59, died suddenly, October 16, of heart disease

Newman Hall Dewis Cox, Baltimore, Baltimore University School of Medicine, 1895 University of Maryland School of Medicine Baltimore, 1902, aged 67, died, October 17, in Richmond, Va

James H Leary, Rush N Y, University of Buffalo School of Medicine, 1897, member of the Medical Society of the State of New York, died, October 21, of carcinoma of the colon and myocarditis

Daniel David Coffey, Chicago, University of Maryland School of Medicine, Baltimore, 1903, for many years manager of the Chicago State Hospital, aged 55, died, November 22 of myocarditis

Cornelius Breckinridge Boyle, Libby, Mont Columbian University Medical Department Washington D C, 1891, aged 71, died October 3, in the Libby General Hospital, of cerebral hemorrhage

H Nelson Amidon Jr, Painesville, Ohio Western Reserve University Medical Department, Cleveland, 1884, formerly county coroner, aged 72, died, October 13, of gastritis and senility

Powhatan P Trueheart, Sterling, Kan., Hospital College of Medicine Louisville, Ky, 1876, member of the Kansas Medical Society, aged 84, died, October 26, of bronchopneumonia

James Gostanian, Detroit, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899, served during the World War, aged 63, died, October 17, of cerebral hemorrhage

Charles Everett Banker, New York Columbia University College of Physicians and Surgeons, New York 1896 aged 70, died, November 24, of angina pectoris and coronary thrombosis

Edgar Hart Ellis, Nutley, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885, aged 76, died, October 10, of carcinoma of the prostate.

Edward Y Walker, Eatonton, Ga., College of Physicians and Surgeons, Baltimore, 1881, aged 78, died, November 5 in a hospital at Atlanta, of arteriosclerosis and hemiplegia

Garner Forseman Parker, Pocatontos, Iowa, Hahnemann Medical College and Hospital, Chicago, 1912, aged 49 died September 28, of x-ray burns received several years ago

John Duncan Stewart ♂ Hartford, Mich Detroit College of Medicine, 1905, served during the World War, aged 56, died, October 3, in the Borgess Hospital, Kalamazoo

Frank Wilbur Cornwell, Plainfield N J New York Homeopathic Medical College, 1900, aged 58, died, October 14, in Los Angeles, of a self inflicted bullet wound

George Randolph Morse, Saskatoon, Sask, Canada Dalhousie University Faculty of Medicine, Halifax, 1902, aged 60 died, August 5, of cerebral hemorrhage.

Eugene Florencio Raphael, Cumberland, Md University of Maryland School of Medicine, Baltimore, 1906, aged 57, died, October 30, of cirrhosis of the liver

Edward E Conrad, New York, Chaddock School of Medicine, Quincy, Ill, 1889, aged 67, died, November 7, in the Memorial Hospital, of adenocarcinoma

Horace Newell Williams ♂ Providence, R I, Bellevue Hospital Medical College, New York, 1882, aged 74, died, November 20, of cerebral hemorrhage.

Olin A Snyder, Schoharie, N Y, Eclectic Medical College of the City of New York, 1879, aged 85, died, October 22 of chronic nephritis and myocarditis

Victor Gregory Foley, Milwaukee, Marquette University School of Medicine, Milwaukee, 1915, aged 43, died, October 18, of carcinoma of the colon

Charles F Cluthe, Evansville, Ind., Medical College of Ohio, Cincinnati, 1891, aged 66, died, October 11, in St. Petersburg, Fla., of angina pectoris

Vladimir Alexis Shlanta, Olyphant, Pa Medico-Chirurgical College of Philadelphia, 1916, aged 42, died suddenly October 15, of heart disease

John Said Perekhan ♂ Chicago, Rush Medical College Chicago, 1888, aged 68 died, November 22, in a local hospital of carcinoma of the stomach

Dexter Horatio Hadley, Pittsford, Mich Northwestern Medical College St Joseph, Mo, 1890, aged 83, died, October 10, of cerebral hemorrhage

Manley Holland Russell, Star City, Ark (licensed in Arkansas in 1903), member of the Arkansas Medical Society aged 62, died, October 25

William L McGavic, Cave City, Ky Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1900 aged 92, died, October 5

Carl E Willan, Trafalgar, Ind., Medical College of Ohio Cincinnati, 1897, aged 63, died, October 1, of cerebral hemorrhage and acute nephritis

Marion X Corbin, Savannah Ga., University of the City of New York Medical Department, 1891, aged 69, died, September 29

Madison G Baldwin, Riverside, Calif Toledo (Ohio) Medical College, 1896, aged 63, died, October 13, of coronary thrombosis

Daniel W Bradfield, Wildersville, Tenn (licensed in Tennessee in 1902), aged 84, died, October 29, of bronchopneumonia

William Walter King, Milnor, N D, Miami Medical College, Cincinnati, 1893, aged 66, died, October 4, of pneumonia

Glenn Robert Keholm, Omaha Creighton University School of Medicine, Omaha, 1935, aged 26, died, September 28

Walter Pope Pillans, Raymondville, Texas, Missouri Medical College, St Louis, 1886, aged 70, died in September

Oliver W Foxworthy ♂ Leon, Iowa, College of Physicians and Surgeons, Keokuk, Iowa, 1884, aged 80, died, October 18

Samuel Dryden Snow, North Conway, N H, Dartmouth Medical School, Hanover, 1897, aged 62, died, September 19

Harry E Koons, Philadelphia, Southern Homeopathic Medical College, Baltimore, 1897, aged 63, died, October 26

William Frank Rhodes, Capleville Tenn, Memphis Hospital Medical College, 1907, aged 61, died, September 25

John T Wages, Macon, Ga., Chattanooga (Tenn) Medical College, 1899 aged 59, died, October 6, at Indian Springs

George H Musekamp, Cheviot Ohio, Medical College of Ohio, Cincinnati, 1884, aged 71, died, September 2

Benjamin Abbott Bradley, Hamlet, Ohio, Pulte Medical College, Cincinnati, 1882, aged 78, died, October 5

Alfred Jefferson ♂ Omaha, Omaha Medical College, 1900 aged 65, died, October 19, of coronary thrombosis

James Richard Smith, Cleveland, Medical College of Ohio, Cincinnati, 1907, aged 57, died, September 21

James Henry Kennedy, Pinola, Miss Gate City Medical College, Dallas, Texas, 1905, died in October

Oston Melton, Laconia, Ind Louisville (Ky) Medical College, 1881, aged 84 died, September 16

Frank S Byington, Los Angeles Louisville (Ky) Medical College, 1896, aged 66, died, December 3

William C Schwier, Knox, Ind., Louisville (Ky) Medical College, 1892, aged 67, died, September 22

Thomas B Hutto, Damascus, Ark. (licensed in Arkansas in 1903), aged 55, died, September 23

SHORT WAVE DIATHERMY

To the Editor—In *THE JOURNAL*, April 6, page 1237, a preliminary report on short wave diathermy by Krusen, published under the auspices of the Council on Physical Therapy, draws attention to the lack of data concerning the biologic effects of the new method and the imperfections and fire hazards of the apparatus. In the time elapsed since, the status of the therapeutic aspects of short wave diathermy has not changed, while the multiplicity of new apparatus and accessories has increased its potential hazards rather than diminished them. The following case may serve as an illustration.

In a woman patient two brand new pliable rubber pad electrodes were applied laterally to the neck, opposite each other without the interposition of any material between the skin and the rubber insulation covering of the metal condenser plates. As soon as the electrical energy from a fifteen meter short wave apparatus was turned on, the patient cried out that she was being burned. The apparatus was shut off immediately and under one electrode a carbonized area of the size of a silver dollar was found. Examination of the electrode revealed that the metal plate inside the rubber covering was not in the center but had slid down. It was covered only by a thin edge of rubber, and as soon as the electric energy was turned on arcing occurred from the metal plate to the skin, this melted the thin rubber covering instantly and inflicted a painful burn, which took several weeks to heal. There was no way for the physician to learn of the defective rubber insulation of the electrode beforehand, which the manufacturer, when called to task, acknowledged.

In addition to this case at least two others were seen in which accidental contact of the electrode cables with each other or with metal furnishings caused melting of the rubber covering and the sudden appearance of flames, frightening and burning the patient. I also know of cases in which there were burns due to overheating under the electrodes.

In administering short waves with the present apparatus, dosage is based entirely on the unreliable factor of subjective sensation of the patient, whereas in ordinary diathermy the meter reading keeps dosage at a safe maximum and enables its duplication at subsequent treatments. Questions of deeper and more uniform heat penetration and its desirability are still unsolved, likewise the problem of selective heating effects.

On the basis of these considerations it is imperative to sound warning against the prevailing campaign to sell short wave apparatus to inexperienced physicians under the claim that it is simpler, safer and more effective than the "old-fashioned" diathermy machine. No physician who is not well grounded in the application of regular diathermy should embark on the use of short wave diathermy apparatus. Notwithstanding the enthusiastic propaganda to the contrary, short wave diathermy is still in the experimental stage and its potential dangers are still problems even for the expert.

RICHARD KOVACS, M.D., New York

DIAGNOSIS OF CINCHOPHEN POISONING

To the Editor—In the clinical note by Dr. Samuel Peluse entitled "Cinchophen Poisoning, with Autopsy Report of a Case Due to Cinsa-Vess" which appeared in *THE JOURNAL* September 28 the author describes in detail the clinical picture presented by a patient suffering from a severe hepatic degeneration. After four weeks of hospitalization and extensive study (as a result of which no precise diagnosis was reached) she was seen by Dr. Andrew Sullivan, who we are told, immediately recognized the patient's clinical picture as one due to cinchophen poisoning. Subsequent questioning of the patient revealed the

fact that she had taken a proprietary preparation of cinchophen over a period of three months prior to the first signs of jaundice. The question paramount in my mind is this: By what means did Dr. Sullivan "immediately recognize the patient's clinical picture as one due to cinchophen poisoning"? So far as I have been able to determine, there is nothing peculiar to the symptomatology resulting from acute yellow atrophy of the liver that might point to etiology. I have always believed that the specific causal factor could be learned only from the history. If, however, in the absence of a history of cinchophen ingestion, Dr. Sullivan can recognize cinchophen poisoning, I am sure we should hear more from him. One other point in Dr. Peluse's article raises a question. He states that "Dr. Sullivan had recently survived a toxic jaundice due to cinchonism." Is it not exceedingly rare for quinine to cause jaundice?

CHARLES S. CAMERON, M.D., Philadelphia

[This letter was referred to Dr. Samuel Peluse, who writes:]

To the Editor—I wish to thank the writer for calling attention to the erroneous use of the term "cinchonism." The following is Dr. Sullivan's response:

"In this instance, although the diagnosis was clearly made without a history and by simple inspection of the patient, there is only one thing that was outstanding in the picture which caused me to differentiate instantly from the jaundice due to an acute catarrhal condition, to obstruction of lithiasis or to obstruction from neoplasm, and that was the uniformly intense deposit of bile pigment throughout the skin. In three other cases which I had seen, the pigmentation was to me characteristic in the uniformity and intensity, although in one case the color varied, the skin of the patient having a greenish hue. In this case, capsules of an unknown substance had been taken over a relatively long period of time. In other words, the whole question simmers down to the fact that I had a relatively large number of cases due to cinchophen poisoning, and the appearance of jaundice of this degree naturally arouses suspicion of cinchophen derivatives having been used. I believe that any one who has seen a number of these cases would receive a similar impression which would cause him immediately to suspect cinchophen compounds in this type of pigmentation and differentiate the majority of cases of jaundice due to other causes."

SAMUEL PELUSE, M.D., Chicago

SPONTANEOUS LATE DESCENT OF THE TESTIS

To the Editor—In *THE JOURNAL*, March 10, 1934, you published my observations on this subject. Although I suspect that general practitioners do not as a rule refer youngsters with undescended testes to surgeons for operation, several articles by surgeons have recently appeared urging operative intervention, and this prompts me to send you this communication. Not content with the Torek operation, which is a two stage procedure, one well known surgeon is now advocating in cases in which there is difficulty in drawing the testis down into the scrotum a preliminary procedure, the testis being brought first to the external inguinal ring and left there until the Torek operation is performed at a later date—a three stage operation.

Operation for this condition being no minor procedure, it would be all the more unfortunate if it should be undertaken unnecessarily. The increased incidence of malignancy in undescended testis which has been reported is such a remote possibility that surgeons as a rule do not give this as indication for operation. The operation is advocated usually in order to prevent atrophy of a testis after puberty. If most undescended testes descend spontaneously by the fourteenth year, this indication for operation is lacking. In my article mentioned, I

reported the experience of others and my own to show that spontaneous late descent does occur in nearly all the cases by the fourteenth year—some even later

To recite briefly the final outcome in my small series of eleven boys (one bilateral case), just one testis has not spontaneously descended to date. Since I wrote the article one of the two reported as still undescended has appeared outside the external inguinal ring, admittedly not at a satisfactory location but where it often remains following operation. One other which descended in the sixteenth year is now midscrotal in position and slightly atrophied. One boy developed a hernia on the side of the late descent, which required operation and later examination failed to disclose the whereabouts of the testis although it was not intentionally removed by the surgeon. In the remaining eight cases the testes are in the normal position low in the scrotum and normal in size.

Surgeons are, I believe, reporting better final results since the adoption of the Torek operation. Before this comparatively new operation the final results, to judge from the literature, were not at all satisfactory.

I am sending you this communication in order to call attention once more to a fact not universally recognized, that rarely is operative intervention for undescended testes indicated, and to save these little chaps from needless discomfort, expense and the certain amount of risk incident to any operation. For my own part I will continue to advise what one surgeon has referred to as my policy of "neglect" rather than to recommend what seems obviously to be meddlesome surgery."

CARL B. DRAKE, M.D., St. Paul

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

DIABETES IN DOCTORS

To the Editor—In a survey on causes of deaths among physicians as reported in THE JOURNAL during 1934 my attention was attracted to the rather high incidence of diabetes fifty-one in all according to the following grouping: fifth decade three, sixth decade seven, seventh decade twenty, eighth decade seventeen, ninth decade three, tenth decade one. I have asked myself: Is it due to negligence or to lack of insulin used or has insulin not proved effective in the higher age groups? What is your explanation?

HANS SCHROEDER, M.D., New Orleans

ANSWER.—Diabetes is not excessive among doctors. Two hundred and twenty physicians died in Massachusetts during 1931 and 1932, according to figures compiled by the Massachusetts Department of Public Health. Diabetes was eighth in importance. For 1933 in the United States the percentage of the deaths of physicians dying of diabetes was 2.1 per cent, and diabetes ranked seventh.

In a certain clinic the average duration of life in ninety-six fatal cases of diabetes in physicians was 10.8 years, and in 1934 145 living physicians (excluding one patient who cannot be traced) under observation at this clinic had already reached ten years. The average age at death of these ninety-six doctors was 63.9 years, and the average age of the living doctors is 55.6 years. As a great proportion of the fatal cases occurred prior to the discovery of insulin, it is evident that the duration of life of the 145 living physicians with diabetes will probably reach fifteen or more years.

The onset of diabetes in the medical profession as based on the data from this clinic runs true to form, because the greatest number developed the disease in the sixth decade. In no instance was the onset in the first decade, there was one case in the second, twenty-four occurred in the third, making it probable that a considerable number of students having diabetes entered medical schools, thirty-six in the fourth, fifty-six in the fifth, seventy-four in the sixth, forty in the seventh, nine in the eighth, none in the ninth, and in two cases the onset date was unknown.

A diabetic heredity in diabetic doctors reaches approximately 33 per cent and presumably is considerably above this figure, because in fourteen of the 242 cases the data on heredity were

unknown or unsatisfactory, and many of the other doctors have not been seen recently. The total heredity was demonstrable in seventy-three cases. In forty-seven it was of a hereditary character and in forty of a familial character, but in fourteen cases it was both hereditary and familial and thus a reduction was made for this double heredity.

Among ninety-six diabetic doctors, tuberculosis and infections each caused 5.2 per cent, cancer 6.2 per cent, coma 15.6 per cent, cardiorenal and vascular disease, including gangrene and apoplexy, 55.2 per cent, and miscellaneous conditions 12.5 per cent of the deaths.

Since the average age of doctors who succumb, 63.9 years, is practically the average age of death of all doctors, it can be inferred that diabetes in doctors is fairly well treated. The fact that 145 living diabetic doctors have already had the disease nearly as long as the doctors who have died of it is evidence of the marked improvement in treatment.

THYROID IN ASTHENIA

To the Editor—For the last four months I have been treating a woman aged 29 married a nullipara who has been complaining of lassitude, tiredness and obesity. A year ago she was under the care of another physician complaining of irregular menstrual periods, a weight of 174 pounds (79 Kg) and the foregoing symptoms. She was placed on 2 grains (0.13 Gm) of thyroid daily, glycerin extract of whole ovary one pill twice a day, and diet, which treatment resulted in a loss of 22 pounds (10 Kg) and partial abatement of symptoms, the menstrual periods became regular but scant, lasting two-three days. My first physical examination of the patient revealed a weight of 165½ pounds (75 Kg), height 5 feet 4 inches (163 cm), pulse 69, blood pressure 130 systolic, 70 diastolic, basal metabolism —17, temperature 98.4 F., a blood count of 4,600,000 red blood cells, hemoglobin 90 per cent, 5,400 white blood cells, polymorphonuclear cells 65 per cent and lymphocytes 36 per cent. Urinalysis was negative. There was a mild edema of the extremities, nonpitting in character suggestive of myxedema. My diagnosis was pituitary-thyroid-ovarian dysfunction. She was put on a 1,500 calory diet, given 1 grain (0.065 Gm) of thyroid extract, 2 grains (0.13 Gm) of anterior pituitary substance and 5 grains (0.3 Gm) of whole ovarian gland three times a day after meals. For the next two months improvement followed; the weight went to 155½ pounds (70.5 Kg), the periods became normal and some diminution of the lethargic feeling resulted. In April her basal metabolism was —5.3 per cent and the lethargic feeling became more pronounced. She had also developed an eruption over her shoulders and neck, it extended into her scalp a short distance. This eruption is reddish brown, papular, flattened, slightly raised, does not produce itching unless aggravated by perspiration and tends to coalesce. The thyroid substance was discontinued for a month but the rash persisted. There is no history of other drugs taken or of food allergy. At the present time the patient is receiving 3 grains (0.2 Gm) of thyroid extract alone daily. Her weight now is 155½ pounds (70.5 Kg), pulse 85, blood pressure 138/84. Please advise me as to the correctness of the treatment. Can thyroid extract produce such a rash (a review of all literature fails to disclose any evidence of thyroid substance producing such a lesion)? Kindly give any suggestions that you can in the diagnosis and treatment of the case. Please omit name.

M.D., New York.

ANSWER.—The use of desiccated thyroid is correct, although if the patient's metabolic rate can be maintained at a normal level with less than 0.2 Gm of thyroid daily it is preferable to use the smaller amount. The use of pituitary and ovarian preparations does not offer much hope in this type of case. It is extremely unlikely that the thyroid has anything to do with the rash. The patient should adhere to a diet low in calories and yet relatively high in protein and vitamins. During the war it was discovered that women who did not receive an adequate amount of protein developed menstrual irregularities. In addition to the vitamins in the diet, it might be well to give the patient brewers' yeast and cod liver oil. Needless to state, the patient should be advised to have plenty of outdoor exercise and to maintain regular hours and habits of living.

USE OF ANESTHETICS BY GWATHMEY METHOD

To the Editor—I wish to place some anesthetic (topical) in the Gwathmey rectal ether oil solution (4 ounce mixture, 2½ ounces of ether) which will make it less irritating. I notice that Babcock's Surgery mentions chlorbutanol Gm 0.6 in an ounce mixture. It is my understanding that chlorbutanol and butyn are the same. Will you state an amount of butyn (2 per cent) that may be safely used in a 4 ounce mixture of oil ether for obstetrics. Please also advise whether the use of olive oil has any advantage over liquid petrolatum as the vehicle.

M.D., Alabama.

ANSWER.—Insert a well lubricated 22 F catheter from 6 to 8 inches into the rectum, passing the presenting part. Instill the rectal mixture within thirty seconds (within a pain interval) instead of fifteen minutes with either a McCormick apparatus or aseptosyringe, with instructions to the patient to "squeeze up" in order to retain the mixture completely. With this technique there will be no irritation, as a rule.

Chlorbutanol and butyn are entirely different in structure and composition. Chlorbutanol, 1 Gm, is used as a routine procedure in surgical cases as a suppository preceding the oil-ether mixture or combined with the mixture for the double purpose of allaying irritation and deepening the anesthesia. Chlorbutanol, 0.65 Gm, could be substituted for paraldehyde, 7.5 cc., in the mixture. Olive oil is commonly used as the vehicle but has no special advantage over liquid petrolatum.

PERSISTENT VAGINAL DISCHARGE

To the Editor—About six weeks ago a married woman of 32 consulted me because of a moderate vaginal discharge for seven months. The woman has one healthy child. There were no miscarriages or abortions and menstruation was normal. There were no urinary symptoms. Physical examination was essentially negative. Examination of the pelvic organs showed slight tenderness and thickening of the right parametrium. There was a moderately profuse purulent discharge from the cervix which, however, appeared to be normal otherwise. The vaginal mucosa was slightly reddened. Repeated smears for gonococci were negative and examination of a hanging drop for *Trichomonas vaginalis* was negative. The blood Wassermann and gonococcus complement fixation tests were negative. The woman received conservative treatment during the past seven months consisting of tampons and douches variously medicated. I continued these procedures, supplementing them with the use of silver nitrophenolate suppositories and the weekly intradermal injection of a solution of lactalbumin. In three or four weeks the discharge cleared up entirely (which it had never done before) and the injections and tampons were discontinued. In two weeks, however, the discharge recurred and at present is as annoying as it was at the beginning. I am writing to ask for information regarding further conservative measures. It is probable that this is a favorable case for the use of local heat in the pelvis. However, I do not have the suitable apparatus but, of course, if this is the only remaining measure will arrange for the patient to obtain the benefits of such treatment. She is interested in knowing whether operative removal of the right tube and ovary in such a case is desirable. I did not feel that the circumstances warranted such a procedure. What do you think about this?

M D New York

ANSWER—The policy of conservatism should be followed in this case. There is no assurance at all that removal of the right tube and ovary will result in the disappearance of the discharge, especially because tubo-ovarian inflammation is a rare cause of vaginal discharge. However, carcinoma of the tube is frequently accompanied by a discharge from the vagina. In spite of the fact that the description of the discharge is not typical of a monilia infection, it is advisable to look for this organism both in hanging drops and in stained smears. If the organism is found, rapid and decided improvement can be obtained by applying a 1 per cent solution of gentian violet all over the vaginal mucosa, the cervix and the vulva. This treatment should be given daily three or four times and another course of treatments repeated after an interval of a week. More hanging drops should be studied for *Trichomonas vaginalis*, especially immediately after a menstrual period. Likewise smears for the gonococcus should be made after the menstrual flow and after silver nitrate has been applied to the cervical canal. Occasionally the offending organism shows up at these times and at no other. Skene's and Bartholin's glands should be carefully examined for gonococci, and it may be advisable to investigate the rectum also for the presence of these bacteria. Naturally, if any pathogenic organisms are found, treatment should be instituted. The use of heat applied locally to the pelvis should be of help to the patient. Perhaps a discussion of the patient's sex life may shed some light on the etiology of the discharge.

FAILURE OF PERIPHERAL CIRCULATION

To the Editor—In your reply to a question in Queries and Minor Notes (THE JOURNAL, June 15 p 2204) concerning digitalis you speak several times of failure of the peripheral circulation as if myocardial and peripheral circulatory failure were separate and distinct things requiring different treatment. Will you be good enough to tell me just what you mean by failure of the peripheral circulation?

COLLINS H. JOHNSTON M D Grand Rapids Mich

ANSWER—In the proper function of the circulation, the normal activity of the heart and that of the peripheral minute vessels constitute the two most important factors. In a healthy person a relationship exists between the function of the heart and the function of the peripheral vessels which results in an economic function of the heart as well as in an economic local supply of blood to the tissues in case of active demand. In instances of disease of the heart, changes in the function of the peripheral minute vessels, particularly of the arterioles and of the venules, often compensate for the inadequate function of the heart. This, of course, also implies that frequently disease and failure of the heart may exist in the presence of normally functioning peripheral blood vessels. Contrariwise, there are

instances in which the function of the peripheral vessels becomes disturbed, in spite of the fact that the heart is not diseased. Such disturbance or disease of the peripheral blood vessels may result in death. When such a situation exists, one may speak of failure of the peripheral circulation. This term is often used synonymously with shock and peripheral collapse.

The detailed mechanism of failure of the peripheral circulation is not known as yet. The main feature of the condition is stagnation of blood in the periphery, usually in the small venous reservoirs of the vascular system. As a result of such stagnation there is a progressive lack of return of venous blood to the right side of the heart. This in turn results in a progressive decrease in the cardiac output and a generalized ischemic state of the arterial circulation. It is claimed by some that the arterioles are in active spasm and the venules in a state of paresis. The heart itself is capable of taking care of whatever blood arrives. The causes of failure of the peripheral circulation may be multiple, the most important etiologic factors, however, are depression of the vasomotor system and paresis of the minute vessels induced by circulating chemical substances. Often failure of the peripheral circulation does not exist in pure form but is associated with failure of the heart also.

As a postoperative circulatory complication, acute or subacute congestive failure of the heart is comparatively rare, while failure of the peripheral circulation (collapse or shock) is relatively common. The principles of treatment of failure of the peripheral circulation in many respects differ essentially from the principles of treatment of heart disease.

SENSITIZATION DERMATITIS

To the Editor—A white man aged 60, whose past history is negative except for smallpox in childhood, has had thickening of the epidermis and cracking and ulceration around the nails for the past twelve years. There is similar but less extensive involvement on other parts of the fingers and also severe itching of the hands and forearms. There are occasional discrete hard white masses about the size of millet seeds which develop in the skin of the fingers and which the patient scratches off from time to time. There is no history of other allergic symptoms or of exposure to any substance that might be responsible. The lesions do not develop crusts, are never purulent and are most severe on the dorsum of the finger completely surrounding the nail the distal phalanx being somewhat swollen. In places the skin is thick and hard with occasional itching and finally deep fissures are formed and desquamation occurs. On the forearms, especially on the flexor surface, the patient has innumerable scratches. He states that a small erythematous patch forms which itches severely. The patient has no other symptoms and physical examination is negative, the blood and urinary examination giving normal results. I doubt that this is infectious in origin and does not conform to my impression of eczema.

M D Illinois

ANSWER—The occupation is not given, but every one has plenty of daily contacts to account for a sensitization dermatitis, which the description of this one suggests. The paronychia is a manifestation of the chronic effects, the small erythematous patches, of the acute ones. The unrestrained scratching of the forearms suggests a nervous element.

The infiltration of chronic inflammation, with possibly some hyperkeratosis, decreases the elasticity of the skin and gives rise to fissuring. The ulceration is probably the result of finger nail removal of the small white bodies. If these are found only on the dorsum of the fingers, they may be milia, subepithelial pellets of hardened sebaceous secretion, which sometimes occur in areas of chronic inflammation. Eczema is a broad enough term to cover a case of this nature.

Further effort should be made to discover the irritant or irritants responsible, but in chronic cases the sensitization is commonly too complicated to be easily unraveled. Alkalis and other irritants should be avoided. For the acute erythematous patches, soothing in place of scratching is recommended, calamine lotion made with equal parts of lime water and rose water, or tragacanth lotion containing 2 Gm of tragacanth powder to 120 cc of water. In these may be incorporated phenol and glycerin, 0.5 per cent of each, or menthol 0.25 per cent.

On the areas of chronic inflammation a zinc oxide paste containing salicylic acid may be applied thickly at night, and cotton gloves or bandages used to retain it. This should be tried first on one finger during waking hours to make sure that it does not irritate. In the morning the paste should be removed with oil or liquid petrolatum and an ointment of sulfur and oil of cade, 5 per cent of each, should be applied. This also should have a preliminary trial. It may be that ordinary crude coal tar ointment, 6 per cent each of crude coal tar and zinc oxide in petrolatum, will be better borne. If irritation results, soothing remedies may be applied. When it subsides, treatment should be resumed.

The nervous element must not be overlooked.

CHEMICAL CAUSES OF NEURITIS

To the Editor—Following is a report of an analysis of a potash used for fertilizing purposes

| | Per Cent |
|--|----------|
| Moisture | 0.2 |
| Potassium chloride | 31.8 |
| Sodium chloride | 46.2 |
| Magnesium chloride | 0.9 |
| Calcium sulphate | 17.2 |
| Aluminum silicate | 3.5 |
| Iron sulphate | Trace |
| (Negative tests for thallium lead arsenic) | 99.8 |

I recently examined a man suffering from a typical case of multiple neuritis and am writing to ask you whether there is anything in this preparation that could possibly constitute the etiologic factor. The man had been unloading potash from the hold of a ship. Several reports have recently been made of longshoremen who have been engaged in unloading this substance complaining of general ill health with no particular symptoms but no other cases of multiple neuritis so far as I know, have occurred.

E. W. APPLEBY, M.D., Houston, Texas

ANSWER—Nothing in the mixture of chemicals cited is likely to lead to a neuritis. Although arsenic is specified as being absent after testing, crude fertilizer chemicals are likely to contain arsenic as an impurity. Arsenic could well account for a multiple neuritis. Of the three major constituents shown, potassium chloride attracts the most attention as a possible toxic agent. Any suspicion is dispelled through the fact that this substance is frequently used in medicine in doses as high as 26 Gm (40 grains). Cushney has been quoted by Addison with respect to potassium salts that "no danger arises to man unless given intravenously." The action of potassium chloride on the peripheral nerves is that of a depressant and therefore conceivably this substance might be utilized in the treatment of a multiple neuritis. When very large doses of potassium chloride are administered (from 5 to 10 Gm) no symptoms may arise except in nephritic states. When poisoning occurs under these circumstances, the chief manifestations are cyanosis, weak pulse and vomiting.

Although this combination of chemicals is regarded as an unpromising source of the causative agent of a multiple neuritis, additional inquiry should be instituted as to other chemicals that may have previously constituted the cargo of the ship. On occasion, relatively small quantities of previous chemical cargoes may react with chemicals making up subsequent cargoes leading to harmful gases, dusts and vapors. Unless some accidental combination of this character has taken place it is unlikely that much consideration should be extended to the chemicals mentioned (in the absence of impurities) as the ultimate cause of a multiple neuritis.

PERSISTENT HEMORRHIAGE AND INFECTION IN EAR

To the Editor—A woman who had a bleeding ear had a mastoid operation after consultation. The wound refused to heal on account of a greenish stain from *Bacillus pyocyaneus*. Reoperation has led to the cessation of bleeding but plenty of greenish exudate and stain. Dilute solution of sodium hypochlorite and the quartz light are now being used. The radical mastoid operation has not been done. Kindly advise me what you think of the case with treatment.

M. D. Delaware

ANSWER—In the absence of any statement as to the length of the discharge from the affected ear or as to the pathologic condition in the middle ear responsible for the bleeding, it is difficult to give a definite opinion. Ordinarily, bleeding from the ear, with the exception of those instances due to a new growth, is due to granulations in the middle ear, the result of a long standing bone disease. Conditions of this character do not yield to a simple mastoid operation. Probably the thing to be considered at present in the way of operative intervention from the symptoms as given is a radical mastoid operation.

ZINC CHLORIDE BURNS

To the Editor—In an automobile radiator manufacturing plant where I do the first aid work a zinc chloride flux with the following formula seems to be the cause of many deep necrotic so-called acid burns. I should appreciate any information you can give me as to the reagent actually causing the burns treatment and suggestions for prevention.

| | |
|--|-------------------------|
| Zinc chloride content | from 47.4 to 48% |
| Ammonium chloride | 3.0 plus or minus 0.50% |
| Free acid as HCl | 0.15% |
| Iron and aluminum total maximum | 0.05% |
| Heavy metals such as lead cadmium and antimony total maximum | 0.05% |
| Please omit name. | |

M. D. New York

ANSWER—The reagent causing the burns is zinc chloride, which is a powerful caustic. Treatment consists in removing the necrotic slough and filling the wound with sodium bicarbonate. Gloves should be worn when handling the flux.

ICTUS WITH APHASIA

To the Editor—A healthy man of 76 walks 2 miles to work every day because he likes it. About 11 a. m. while urinating but with no particular effort, he started to say something but discovered that he could only mumble unintelligibly. Being a telegraph operator he tried communication by telegraph with another operator in the office and it worked perfectly. He could not use a typewriter quite as usual as he kept striking too close. The blood pressure is 110 systolic 70 diastolic. Examination of the urine gives negative results. The heart is normal. In about an hour and a half improvement began and in another half hour recovery was complete. Hysteria and neurosis are utterly out of the question. It was very galling to his pride. There were no previous symptoms pain or muscle impairment except that he felt as though his mouth were drawn to one side at first. It was symmetrical when I arrived. What is the probable explanation?

M. D. Michigan

ANSWER—The history given sounds as if the patient had a small ictus. It is possible that this was due to a thrombosis of a small blood vessel, which produced the symptom of aphasia because of the associated edema. When this edema cleared up his ability to talk returned, as evidently the thrombosis did produce a softening in the speech center. It is likely that the patient will have further attacks of a similar nature.

TREATMENT OF LOCOMOTOR ATAXIA

To the Editor—I would appreciate some information as to the best treatment of a case of beginning tabes in a woman aged 44. She has had syphilis for a number of years. The blood Wassermann reaction has been negative for the last two years. A recent spinal fluid reaction was slightly positive with 0.2 and 1 cc. The colloidal gold test is 0122100000. Ross Jones and Noguchi faintly positive. The patient is beginning to show the early symptoms of tabes as a velvety feeling of the feet and stumbling in the dark. Please omit name.

M. D., Wisconsin

ANSWER—The special method of treatment in this case is probably that which Stokes terms the mild routine treatment. Neoarsphenamine in doses of 0.45 Gm. should be given intravenously twice a week for six weeks, accompanied by the administration of a heavy metal. For this purpose a 50 per cent mercurial unguent should be rubbed into the extremities four times a week during the six weeks course of neoarsphenamine. In administration, care should be taken to avoid mercurialism. A rest period of two or three months should be given before another course, followed by careful reexamination of the patient.

EMPTYING SEMINAL VESICLES

To the Editor—A man aged 31 with a history of urethritis five years ago and a relapse three years later complains of deficient erection and premature ejaculation. This condition antedated the infection. Examination shows a morning drop containing many pus cells. Prostatic massage shows the prostate about normal in size and 2 cc. of secretion obtained shows about 20 pus cells to a high power field and many sperms. The seminal vesicles can be outlined as being quite distended but are beyond the point at which adequate finger pressure can be applied in order to evacuate their contents. For the past month the patient has been treated with massage, urethral irrigation of potassium permanganate, posterior urethral instillation of 1 per cent silver nitrate, and foreign protein intramuscular injection twice a week. Sounds are passed preliminary to the instillations. Is there any means at hand of securing emptying of the seminal vesicles and is there any efficient instrument available on the market for this purpose in such cases? At present he practices rather unsatisfactory intercourse about once a week. Would a normal orgasm produce appreciable emptying of the seminal vesicles as described?

M. D. New Jersey

ANSWER—There is an instrument on the market which can be fastened to the index finger for the purpose of carrying out high rectal massage. This should be used with caution, as it is difficult at times to judge the amount of pressure produced. A normal orgasm will empty the seminal vesicles fairly well, provided the ejaculatory ducts are patent. These are frequently narrowed as the result of inflammation, or blocked by the products of inflammation, preventing thorough emptying of the vesicles.

NAUSEA AT MENSTRUAL PERIOD

To the Editor—A single woman aged 35 has attacks of nausea every time she menstruates. This phenomenon has occurred with regularity for the last six times that she has menstruated. When she finishes menstruating the nausea subsides immediately. I thought that this may be associated with some endocrine dysfunction but I am unable to figure it out. Would you suggest using endocrine preparations?

M. D. Pennsylvania

ANSWER—Since this patient has arrived at the age at which marriage and childbearing seem remote to her, there may be a strong psychic factor in the occurrence of the nausea during the menstrual periods. However, it is advisable to try to rule out any organic disturbance in the gastro-intestinal tract, par-

ticularly in the gallbladder. Endocrine therapy will most likely be helpful only if it has an effect on the psyche. If no organic disturbance can be detected, a frank discussion of the patient's outlook on her future may prove of value.

TOXICITY OF METHYL ETHYL KETONE—BUTANONE

To the Editor—Will you kindly supply me with information concerning methyl ethyl ketone also known as butanone. This substance is mixed with benzene in the proportion of 40 per cent butanone and 60 per cent benzene and used as a solvent in a certain process of petroleum refining. Owing to the nature of this process employees might be subjected to skin exposure to the liquid form as well as to the vapor form. Also the fumes or vapors might be inhaled by employees from time to time. I understand that the product is manufactured by the Shell Chemical Company but I do not know its address. I also understand that this company is the first to use methyl ethyl ketone on a commercial basis although this product has been a laboratory chemical for some time. So far I have had a little clinical experience with the effects of the benzene methyl ethyl ketone mixture. The effects which I have observed are as follows: 1. Effects on the skin. A reddening and the patients have complained of a stinging and burning sensation over the affected areas. It is my opinion that these areas would have blistered soon if treatment had not been given. 2. Effects on the respiratory system. Hoarseness, complaint of a burning stinging sensation in the nose, throat and lungs, increased rate and depth of respiration, slight reddening of the mucosa of the nose and throat. 3. General effects. Headache, vertigo, nausea, vomiting, a feeling as if the patient were floating away, increased pulse rate and a feeling of weakness in the legs. All these effects have apparently been transitory, with no permanent ill effects. I have noted no symptoms or signs after forty-eight hours following the exposure. All cases that I have seen have been acute and I have not seen any chronic effects. The information that I desire consists of the possible and probable effects of the liquid as well as the gaseous form. The treatment that I have used has been bismuth paste for the skin lesions, aromatic spirit of ammonia by mouth and by inhalation and mild protein silver into the eyes and nostrils. Soap and water are applied to the skin prior to the paste. Does this treatment seem adequate? If not, what treatment do you recommend? What procedure do you suggest for checking up on the possible ill effects on workmen handling the benzene methyl ethyl ketone combination? In other words, please give me all the available information concerning the diagnosis, treatment, prevention and possible ill effects of the liquid and gaseous forms of the benzene methyl ethyl ketone combination described.

M D Texas

ANSWER.—It is presumed that, in this mixture of 60 per cent benzene and 40 per cent methyl ethyl ketone, no new chemical is produced and that the two substances mentioned remain as entities. Of these two, benzene (benzol) is far more toxic. Methyl ethyl ketone is not known to possess toxic properties beyond the capacity to defat the skin and thus pave the way for minor dermatitis. The ketones are ordinarily rated as having about the same toxicity as acetone. This matter is discussed by Loevenhart, Kerr and Walton in "A Comparison of the Pharmacological Action of Diacetone Alcohol and Acetone" (*J Pharmacol & Exper Therap* 33:175, 1928). On the other hand, benzene is a highly dangerous substance to which workers should not be subjected under conditions that lead to the inhalation of vapors in concentrations above 300 to 500 parts per million parts of air. Benzene may be absorbed through the skin, although this portal of entry is not well established as a source of systemic benzene poisoning. Like methyl ethyl ketone, benzene serves as a defatting agent for the skin and readily leads to a dermatitis. The effects are described as "general" and "on the respiratory system" are fairly characteristic of acute benzene poisoning. It is predicted that any consistent exposure will eventuate in direful chronic manifestations. Examinations of the blood should be made for leukopenia, diminutions in the total red count, hemoglobin and increase in the clotting time of the blood. Extensive information on benzene poisoning will be found in the publication by McCord and others entitled "Benzol (Benzene) Poisoning," 1932. The treatment mentioned may be adequate on a symptomatic basis but much more extensive preventive measures should be undertaken. Direct contact with the skin should be obviated. The inhalation of more than 500 parts of the mixture by workers should not be tolerated. The wearing of respirators as a means of protection against benzene is ordinarily not efficacious. The wearing of positive pressure helmets may provide adequate protection, but such practice is onerous for workmen and impossible unless the work is fairly closely limited to fixed areas such as ordinarily does not prevail around petroleum refineries. Completely enclosed systems or venting systems have proved to be safest in providing acceptable work conditions in connection with the utilization of benzene under conditions otherwise favorable to high concentrations of vapors that might be respired by workers.

Alice Hamilton in her textbook (*Industrial Toxicology*, New York, Harper & Bros., 1934, p. 156) says in regard to benzene

"It is so recognized [as the most dangerous poison in industry with the exception of tetrachlorethane], and its use has been abandoned, often at a good deal of sacrifice, by conscientious employers who refuse to subject their workers to such a risk. But apparently as soon as it is given up in one industry it is adopted in another, and eternal vigilance is needed if chronic benzol poisoning is to be prevented."

DIAGNOSIS OF PERNICIOUS ANEMIA

To the Editor—A white woman aged 60, widowed, had been feeling weak for six weeks with palpitation of the heart and fainting spells. She stated that she had been conscious of lack of blood for the past twenty years. She had an operation for goiter at the Mayo Clinic in 1915. She had associated symptoms of palpitation, syncope, a tingling sensation in the feet and hands, sore tongue and diarrhea with an absence of hydrochloric acid in the Ewald test and splenomegaly. Pernicious anemia was diagnosed and she was placed on dilute hydrochloric acid and raw liver on which diet she gained 38 pounds (17 Kg.) Jan. 29, 1934. 3 cc. of concentrated solution liver extract every other day was prescribed. At that time the blood count was 1,980,000 with 46 per cent hemoglobin. Reticulocyte response was immediate, so that on January 31 it was 6.4 per cent, February 2, 12 per cent, February 5, 11.6 per cent, February 7, 7.2 per cent, February 9, 5 per cent. The first rise occurred on February 2 with the second rise February 19. The erythrocytes increased from 1,980,000 with 46 per cent hemoglobin at the beginning of treatment to a maximum of 6,300,000 with 110 per cent hemoglobin (photometer) and 2 per cent reticulocytes on May 5. The liver medication was discontinued on March 2 at which time the erythrocyte count was 5,030,000, with 100 per cent hemoglobin. The reticulocytes numbered 2 per cent. The leukocyte count ranged from 6,800 with 46 per cent polymorphonuclears, 52 per cent lymphocytes and 1 per cent eosinophils prior to the administration of liver to between 6,000 and 8,000 with 74 per cent polymorphonuclears, 26 per cent lymphocytes except for a period between February 19 and March 2 when an acute infection of the upper respiratory tract brought the leukocyte count up to 12,000 or over, with 82 per cent polymorphonuclears, 12 per cent lymphocytes and 6 per cent eosinophils. Additional laboratory reports April 25, 1934, revealed a negative Wassermann reaction, nonprotein nitrogen 46, urea 15, uric acid 6.4, creatinine 1.5, sugar 125. When the fragility of the blood was tested, hemolysis began at 0.48 per cent and was completed at 0.32 per cent. Marked hemolysis occurred up to 0.44 per cent. Control 1.2. Hemolysis began at 0.46 per cent and was not completed at 0.28 per cent. Marked hemolysis occurred up to 0.36 per cent. The gastric contents showed a heavy trace of bile, complete absence of hydrochloric acid, total acid 7 and no occult blood. The patient was next observed Jan. 15, 1935, because of a cellulitis of the left leg due to injury. The temperature was 100 and the respiration rate 24. Leukocytes numbered 17,000 with 88 per cent polymorphonuclears. Hemoglobin was 110 per cent. There were 4,700,000 erythrocytes. The patient was next seen April 24 when the erythrocytes numbered 6,200,000 with 135 per cent hemoglobin (Sahli). The leukocytes numbered 12,400 with 85 per cent polymorphonuclears. The erythrocytes increased to 6,330,000 with 142 per cent hemoglobin (Sahli) at which time the patient died, apparently from cardiac failure, general debility and polycythemia. This is rather an unusual picture to have gone from oligocythemia to polycythemia particularly after the liver had been discontinued for a period of three months. I felt sure that the case had all the earmarks of a pernicious anemia owing to the reticulocyte response to liver, the absence of hydrochloric acid, the absence of a vibratory sense in the bones and other neurologic changes. Have there been any such cases reported in medical literature?

M D Oklahoma

ANSWER.—There appears to be no reference in the literature to a case with exactly the characteristics of this one. Naegeli (*Blutkrankheiten und Blutdiagnostik*, 1931, p. 577) mentions a "reparative polyglobuly" during the period of compensation after anemias. The exact nature of the anemia in this patient is not clear from the data given. There may have been myxedema following the "operation for goiter." An anemia of this type, with response to liver therapy, may occur during the course of cirrhosis of the liver. The splenomegaly, rare in true pernicious anemia, is compatible with this. The response to liver therapy is quite unusual, quantitatively, especially the continuation of the rise in the number of red blood cells for such a long period after the cessation of the treatment. It is suggestive of the polycythemia that accompanies, at times, cardiac decompensation. Absence of vibratory sense and non-secretion of hydrochloric acid may be characteristic of other conditions besides pernicious anemia.

CRACKING NOISE IN JAWS

To the Editor—A woman aged 19 after a tonsillectomy some years ago developed a cracking noise on opening her mouth. I believe that this condition is termed clacking jaw. At present she has great discomfort on eating or having dental work done. What is the most advisable treatment for this condition?

SAMUEL J. HILLER, M.D., Milwaukee

ANSWER.—The condition is brought about by an irritation of the synovial membrane of the temporomaxillary articulation (glenoid fossa). It is caused either by trauma, such as opening

the jaw too wide or holding it open too wide for too long a period, or by paralysis of the nerve innervation to the membrane.

The treatment in these cases is complete rest and massage. It may be necessary to ligate the teeth into occlusion for two or three weeks in order to reduce the inflammation of the membrane. It is then necessary to watch that the patient does not open the mouth too wide in eating, yawning or having dental work done, until the condition is cured. The massage should be light and over the area of the head of the condyle, should begin at once and should continue until the cure is complete.

BLOOD TESTS FOR PATERNITY

To the Editor—Will you please tell me how old an infant should be before agglutination tests can be used to determine his paternity? I understand of course that these tests only eliminate certain men as parents. But I want to know how old the infant should be before they can be depended on.

M D New York

ANSWER—In cases of disputed paternity, reliable results can be obtained even when the blood of new-born infants is tested. Although it is true that as a rule the blood group is not completely developed at birth, this in no way interferes with the determination of the blood group. The reason for this is that the defect involves only the iso-agglutinins in the child's serum, since the agglutinogens are present in the red blood cells at birth. For the determination of the blood group, the usual procedure is to test the unknown blood cell suspension with known serums of group A and group B. The converse test, of the patient's serum against known blood cells of groups A and B, serves as a useful check on the grouping, which, incidentally, should never be omitted in forensic cases but which is not absolutely essential. This check is naturally not available when infant's blood is tested, but if testing serums of high potency are used, the group can be reliably determined by testing the red cells alone. If any doubt remains, the blood should be retested at a later date, after the agglutinins have developed.

CANNABIS INDICA—ALCOHOL—KETOGENIC DIET IN EPILEPSY

To the Editor—I will appreciate information on the chemistry and physiologic action of Cannabis indica in fact anything written authoritatively on this subject. What is the physiologic action of alcohol on the sympathetic nervous system including the adrenals? What is the latest treatment of epilepsy based on scientific principles and not on wishful thinking? What is the scientific explanation for the use of the ketogenic diet in epilepsy? Can you give me any good authors on these subjects?

E J AAVIS M D Philadelphia

ANSWER—Louis Lewin's book "Phantastica" (New York, E P Dutton & Co, 1931) may give satisfactory information on cannabis indica. Authoritative discussion of the action of cannabis as well as alcohol may be found in such books on pharmacology as that of Torald Sollmann (Philadelphia, W B Saunders Company). In "The Treatment of Epilepsy," by Fritz B Talbot (New York, Macmillan Company, 1930), a good book on the subject, the author says "Our understanding of the mode of action of the ketogenic diet may be summarized as follows. Whether the dehydration associated with the ketogenic regimen is the important therapeutic factor or whether the effectiveness of ketosis is to be ascribed to some unknown or unrecognized factor has not yet been demonstrated. About all that can be said therefore in conclusion is that the ketogenic diet appears to be the most effective form of the dietetic treatment of epilepsy."

DIET IN KIDNEY STONES

To the Editor—Recently a man aged 33 consulted me regarding kidney stones which he has been passing intermittently for the past five years. The stones are small and the chemical analysis indicates calcium oxalate, calcium phosphate and calcium carbonate. Will you please give me information regarding diet in such cases. He has not been taking soda and has no stomach disorder. His general health is excellent.

RADFORD F PITMAN M D Kansas City, Mo

ANSWER—The most important item in the diet is an abundance of water, at least half a gallon each day. The oxaluria requires a restriction of those foods which are rich in oxalates, most especially spinach, potatoes, beets, beans, endive, rhubarb, tomatoes, figs, plums, currants, strawberries, cocoa, chocolate and tea. The tendency to precipitation of calcium phosphate and carbonate should be antagonized by increasing the acidity of the urine, most especially by a diet rich in meat, eggs and cereals, with but little of fruit and vegetables, and no milk, as this is rich in calcium.

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Written examination for Group B applicants will be held in various cities throughout the country March 14. Oral examination for Group A and B applicants will be held in Kansas City Mo, May 11-12. Applications for written examination should be filed with the secretary before Jan 15. Sec. Dr C Guy Lane 416 Marlboro St, Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada March 28. Applications must be filed not later than February 28. Oral clinical and pathological examination of all candidates will be held in Kansas City Mo May 11-12. Applications must be received not later than April 1. Sec. Dr Paul Titus 1015 Highland Bldg Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY Kansas City Mo May 11 and New York Oct. All applications and case reports must be filed sixty days before date of examination. Asst Sec Dr Thomas D Allen 122 S Michigan Ave Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St Louis Jan. 11. Sec. Dr Fremont A Chandler 180 N Michigan Ave, Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY Kansas City, Mo., May 9. Sec. Dr W P Wherry, 1500 Medical Arts Bldg Omaha.

AMERICAN BOARD OF PEDIATRICS Kansas City Mo May 9. Sec. Dr C A Aldrich 723 Elm St Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York, Dec. 30. Sec. Dr Walter Freeman 1726 Eye St N W, Washington D C.

COLORADO Denver, Jan 7. Sec., Dr Harvey W Snyder 422 State Office Bldg Denver.

CONNECTICUT Basic Science New Haven Feb 8. Prerequisite to license examination. Address State Board of Healing Arts 1895 Yale Station New Haven.

DISTRICT OF COLUMBIA Washington Jan 13-14. Sec., Commission on Licensure Dr George C Ruhland 203 District Bldg Washington.

HAWAII Honolulu Jan 13-16. Sec. Dr James A Morgan, 48 Young Bldg., Honolulu.

ILLINOIS Chicago Jan 28-30. Superintendent of Registration, Department of Registration and Education Mr Homer J Byrd Springfield.

MINNESOTA Basic Science Minneapolis Jan 7-8. Sec. Dr J C McKinley 126 Millard Hall University of Minnesota Minneapolis.

MEDICAL MINNEAPOLIS, Jan 21-23. Sec. Dr Julian F Du Bois 350 St. Peter St. St. Paul.

NATIONAL BOARD OF MEDICAL EXAMINERS Parts I and II Feb 17, 14, May 6-8 June 22-24 and Sept 14-16. Part III tentatively scheduled as follows Chicago Jan 7-9 and New York, Jan 13-15. Ex. Sec., Mr Everett S Elwood 225 S 15th St. Philadelphia.

NEBRASKA Basic Science Omaha Jan 14-15. Dir. Bureau of Examining Boards Mrs Clark Perkins State House, Lincoln.

NEVADA Reciprocity Carson City Feb 3. Sec., Dr Edward E. Hamer Carson City.

NEW YORK Albany Buffalo New York and Syracuse Jan. 27-30. Chief, Professional Examinations Bureau Mr Herbert J Hamilton 315 Education Bldg Albany.

NORTH DAKOTA Grand Forks Jan 7-10. Sec. Dr G M Williams 445 S 3d St Grand Forks.

OREGON Portland Jan 7-9. Sec. Dr Joseph F Wood 509 Selling Bldg Portland.

RHODE ISLAND Providence Jan 23. Dir. Department of Public Health Dr Edward A McLaughlin 319 State Office Bldg Providence.

SOUTH DAKOTA Pierre Jan 21-22. Dir. Division of Medical Licensure, Dr Park B Jenkins, Pierre.

WASHINGTON Basic Science Seattle Jan 9-10. Medical Seattle Jan 13-15. Dir. Department of Licenses Mr Harry C Huse Olympia.

WISCONSIN Madison Jan 14-16. Sec. Dr Robert E Flynn 410 Main St, La Crosse.

Maryland June Examination

Dr John T O'Mara, secretary, Board of Medical Examiners of Maryland, reports the written examination held in Baltimore, June 18-21, 1935. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and fifty-five candidates were examined, 135 of whom passed and 20 failed. The following schools were represented:

| School | PASSED | Year Grad | Per Cent |

Book Notices

Paying Through the Teeth By Bissell B Palmer DDS F.A.C.D.
Cloth Price \$2 Pp 297 with 9 Illustrations New York Vanguard Press 1935

The subtitle of this book, "A Critical Analysis of Dental Nostrums" describes in a sentence the character and scope of the work. The book does for the dental field what "Nostrums and Quackery" published by the American Medical Association does for the medical field. It gives names and calls a spade a spade; it gives the lay public sound and definite information regarding nostrums sold in the dental field.

Dr Palmer while giving due credit to the American Dental Association and, where necessary, to the American Medical Association, for the factual data presented in his book, does not attempt to belittle either of these great organizations. It is true that in one place he does criticize a group of advertisements that appeared in THE JOURNAL, although admitting that THE JOURNAL is "ordinarily most circumspect" in its advertising. Curiously enough, Dr Palmer fails to bring out what we believe was a fact that the official journal of the national dental organization carried the same advertisements.

"Paying Through the Teeth" should and will we believe, do a very useful piece of educational work. Dr Palmer is of the opinion that the vigorous action of the American Medical Association against the patent medicine evil resulted in many concerns in the "patent medicine" group turning their attention to the marketing of dental nostrums for, as the author so well brings out, the American dental profession, until comparatively recently made no attempt to protect the public against dental frauds. Dr Palmer falls into the common error of confusing the American Medical Association's Council on Pharmacy and Chemistry with the Association's Bureau of Investigation. The Council does not concern itself with those cruder proprietaries that are commonly called 'patent medicines', it confines its activities largely to the proprietary remedies that are sold nominally, at least, for the use of the medical profession for prescription purposes. It is the Association's Bureau of Investigation that has carried on a campaign for more than a quarter of a century against the crude nostrums colloquially called patent medicines."

Dr Palmer does well to bring out as he does in chapter 13 the pernicious commercial influences that have attempted to control the dental profession and which apparently still wield considerable power. His profession is having the same fight to overcome the commercial domination of dentistry that the medical profession, through the American Medical Association had to overcome a similar domination in the medical field. The thoughtful members of the medical profession who are familiar with the facts will agree with Dr Palmer in his statement that the dental profession has gone far, and is steadily progressing, toward acceptance of its full duty to protect the public against the use of nostrums and against the impositions and frauds of dishonest advertising."

"Paying Through the Teeth" is a good book for the physician to have in his reference library for it contains in easily available form a vast amount of information on tooth pastes, tooth powders, mouth washes, pyorrhea remedies and similar preparations. The book has an excellent index.

Basic Problems of Criminology By Professor Olof Kimberg M.D.
Boards Pp 438 Copenhagen Levin & Munksgaard 1935

Professor Kimberg is a leader in the study of medical jurisprudence with particular reference to Sweden and to the insane. For almost thirty years he has been studying the problems of criminal psychiatry and his shorter writings are known in this country. The present work is a massive rather thorough study of criminal 'responsibility,' for which term the author prefers an obsolescent term 'imputability.' The volume opens with a historical introduction to the subject of psychiatric criminology which is of much value because it supplements such American works as those of Weihen and Glueck (which confine themselves to English and American law) by presenting the Teutonic genesis of the subject. While many legal philosophers have discussed causes of crime, Kimberg presents a new philosophical approach. He devotes a good portion of the

historical part of the book to the development, from the classical period to the present, of the concepts of blame and punishment. About the last three fifths of the work is devoted to a careful analysis of the causes of crime, the situational picture surrounding crimes and criminals, and the attitude taken toward the whole subject by various criminological writers. To the American criminal psychiatrist the author's analysis of the criminal's mental processes and the causation of his acts may seem to be a rehash of already published criminological philosophy, still it is excellently done and European sources have been explored which tend to validate and agree with much American material previously needing confirmation. Kinberg is not, of course, down to date in his knowledge of criminology in this country, for much of the best work, like that being done by the Illinois state criminologist, is unpublished or only recently has been put into print. For a foreign publication in English, the style is satisfactory and in some places makes excellent reading. This volume belongs in the library of every potential or actual forensic psychiatrist.

A Textbook of Physiology. By William D. Zoethout, Ph.D., Professor of Physiology in the Chicago College of Dental Surgery (Loyola University). Fifth edition. Cloth. Price \$4. Pp. 694 with 271 illustrations. St. Louis: C. V. Mosby Company, 1935.

This well known textbook has been extensively rewritten in regard to endocrinology, nutrition and neurophysiology. The book is suitable for intermediate courses in physiology and should be intelligible to students with little previous knowledge of anatomy or biochemistry. There is a great deal of reliable information in the volume, although some of it has been too greatly condensed to be readily grasped. Occasionally it is difficult to agree with the author's choice of interpretations. For example, although he says that Hering's theory of color vision is less commonly accepted than Helmholtz's theory, he describes only the former. The physiology of the circulation occupies ninety pages, yet there is no mention of the electrocardiogram. A paragraph is devoted to the "staircase" phenomenon and one to tetanus in heart muscle. An incomprehensible picture of Dudgeon's sphygmograph, among other illustrations of obsolete apparatus, might well be eliminated from future editions. For a textbook in physiology there would not seem to be need for six semidiagrammatic illustrations of the mammalian heart to show the direction of blood flow and the function of the valves. There is no mention of the carotid sinus reflex mechanism. It is obvious from the abundance of anatomic illustrations that the book is intended for nonmedical students. A glossary adds considerably to its value for such students. As a relatively up to date treatment of the subject it can be highly recommended to the intermediate student group.

Gastritis and Its Consequences. By Knud Faber, M.D., LL.D.E., F.R.C.P.E.Hon., Professor of Internal Medicine in the University of Copenhagen. Cloth. Price \$3. Pp. 119 with 48 illustrations. New York & London: Oxford University Press, 1935.

This little monograph presents the views of Dr. Knud Faber, based solely on his personal experience with gastritis over a period of forty years. There are three parts, the first on acute and chronic gastritis, the second on gastritis and hyperacidity, and the third on gastritis and anacidity. The subject of gastritis is an interesting one in that about thirty years ago the term was a diagnostic one to be frowned on for many years and to reappear recently as the result of examination of the stomach itself by direct vision, gastroscopy, and of the tissues removed by resection of the stomach for ulcer or carcinoma. The author's method of immediate postmortem, intragastric injection of 4 per cent solution of formaldehyde has made it possible to obtain tissues that have not undergone lytic degeneration and to report the true story of what he thinks gastritis really is. This work has been done by many others, whose conclusions are in accord with the author's. Tracing the condition from simple gastritis with slight or no dyspeptic symptoms and few local changes, he carried the work through the stages of acute and chronic gastritis and showed that chronic gastritis is frequently the results of repeated or acute gastritis. It may be of the erosive or pangastritic and atrophic type, the latter being the form in which anacidity is most common. Gastritis with hyperacidity may be the forerunner of peptic

ulcer, is generally associated with it, and not infrequently may give rise to the symptoms characteristic of ulcer, even hemorrhage without an ulcer being found on roentgen examination or at operation. The small acute ulcers that are often seen in the picture of severe gastritis may be the forerunner of the chronic peptic ulcer. The author says that the causes of anacidity are veiled in indefinite beginnings and that in his experience gastritis is always present wherever anacidity is found. He does not believe in the constitutional factor as a cause of anacidity, as Hurst does. The frequency of the occurrence of low or anacid states in the course of acute infections and intoxications the existence of which may have been forgotten, the many opportunities for the development of gastritis in the course of a lifetime from infancy to late adulthood, the tendency either to forget or to overlook trivial disturbances, are all sufficient reasons for postulating the presence of gastritis at some time or other which subsequently becomes severe enough to cause anacidity. Pyloric gastritis does but cardiac does not produce anacidity. The anacidity late in life looked on as normal is in the author's experience the result of gastritis, likewise the anacidity that may be the precursor and is always the accompaniment of pernicious anemia. The rare return of gastric acidity in this condition is the result of a recession of pyloric gastritis. Hypochromic anemia and anacidity may bear the same relationship. One cannot digress into a discussion with the author, because he makes these observations as his own personal opinion, even though he knows that many disagree with him. It is a well written book, reads well and is worthy of being scanned by any one interested in internal medicine. Attention might be called to the tautologic "X-ray Radiograms" on page 13 and "imitation" for "irritation" on page 32. There is a large bibliography.

Sex Worship and Disease (Phallic Worship). A Scientific Treatise on Sex Worship and Its Influence on Religion and Symbolism with Special Reference to Disease of the Sexual Organs. By Mason Daugherty, M.D. Cloth. Price \$3.50. Pp. 240 with 21 illustrations. Cleveland, Ohio: The Author, 1935.

There seems to be little reason for the appearance of a book of this sort even though the author does say that it was written for the physician (called a scientific treatise on the title page) and for his friends. Possibly the many lay friends of the physician, seeking information on that always interesting subject, sex, are meant in particular. The doctor is not forgotten, because the unfortunate victim of venereal disease is cautioned against going to an advertising quack, but to an "M.D." [sic]. Chapters on venereal disease, the evils of masturbation, care of the teeth, cancer of the breast, leukorrhea, a recital of Nero's cruelties and a new deal for women alternate in an irregular fashion with discourses on phallic worship, the anatomy of the generative organs, prostitution, marriage customs, birth control and early marriages among the Hindus. The information is too fragmentary to be of any value to a physician or to the layman seeking knowledge. Neither the manner of offering the information nor its literary qualities can recommend it to the intelligent reader.

Prognosis. Volume One. [Reprinted from the *Lancet*.] Cloth. Price, 10s. 6d. Pp. 372. London: Lancet Limited, 1935.

This is a companion volume to the previously published series on "Modern Technique in Treatment" and "Clinical Interpretation of Aids to Diagnosis." It contains, as did the others, a collection of articles published week by week in the *Lancet*. To the writing of each article the editorial staff invited those who have watched the progress of large numbers of cases of certain diseases to share this experience with their colleagues in more general practice. The choice seems to have been a happy one in each case for in every chapter one senses the word authority. "Of the three great branches of clinical science—diagnosis, prognosis and treatment, prognosis is admittedly the most difficult," says Robert Hutchinson. Hence it ought to be studied all the more assiduously. It is, indeed, just as true of prognosis as it is of diagnosis that neither of them can be separated from treatment. The three are merely different aspects of therapy "if we define this word, in its widest sense, serving the best interests of the sick." Thus says T. A. Ross, in his introduction to the chapter on "Prognosis in Hysteria and Anxiety States." It is of interest when

reading contributions on the subject of prognosis to note that nearly every author is compelled to make constant reference to treatment. Therapeutics are scoffed at so often that it is gratifying to find that hardly any one is in a position to discuss prognosis helpfully without doing this. It has been made abundantly clear in several articles in this series that in many illnesses prognosis depends not only on the nature of the illness but on the facilities for treatment which can be afforded. There are of course certain conditions such as coryza where whatever is done it is as near certainty as possible that the patient will become quite well, there are others, like established hydrophobia, where it is almost equally certain that he will die, but for probably a majority of illnesses prognosis depends to a great extent on treatment, and certainly this is true of the two psychoneuroses hysteria and anxiety states. No physician, be he specialist or generalist, can peruse this book without becoming a better doctor than he was.

Human Pathology A Textbook By Howard T. Karsner M.D. Professor of Pathology Western Reserve University Cleveland Ohio. With an Introduction by Simon Flexner M.D. Fourth edition. Cloth. Price \$10. Pp. 1213 with 461 illustrations. Philadelphia & London J. B. Lippincott Company 1935.

The first edition of this textbook appeared in 1926, this, the fourth edition in nine years, represents the efforts of the author "to keep the work wholly abreast of the times." This attempt is apparent in the careful way in which Dr. Karsner has revised the book. Many sections have been completely rewritten, new illustrations added or better ones substituted for previous ones, and the references at the close of each chapter modernized. The chapter on the general pathology of tumors has been rewritten and much new material has been added to the sections on diseases of the blood, diseases of the nervous system, and the pathology of the ductless glands and of the granulomas. Other subjects have been revised in the light of newer information, making the work much more satisfactory for teachers and advanced students.

Criticism of this book is made difficult by the fact that the author has attempted the impossible object of treating the subjects of general and special pathology in one volume that will be useful to students as well as to advanced workers in the field. He has succeeded better for the latter group than for the former. For beginning students further simplification would make the sections on general pathology more comprehensible. For example, the long paragraphs on pages 129 to 134 are rather confusing to beginners. Future editions might well include a general chapter on parasitic diseases written from the pathologic point of view. The book as a whole, however, will continue to serve and to inspire all students of pathology even more completely than it has in the previous editions. American pathologists may well be proud of Dr. Karsner's achievements in this textbook.

Psicologia social Pelo Professor Raul Briquet, catedrático da faculdade de medicina da Universidade de São Paulo. Paper. Pp. 265 with 10 illustrations. Rio de Janeiro São Paulo & Belo Horizonte Livraria Francisco Alzira Paulo de Azevedo & Cia 1935.

This book is a modern presentation of some of the more superficial facts of social psychology. It is somewhat less scientific and less exact than most American books, such as those of Bernard and Allport, and consists largely of quotations from authors on the various subjects discussed. The style is simple if one reads Portuguese, but there seems to be no reason for any American reading the present volume. The most important contributions discussed in it are those of Americans and are well known to the majority of people interested in social psychology. Its chief source of interest, however, is in its approach. It consists of two parts: the first is a general discussion covering such topics as the importance of biology and psychology and sociology to the subject in general. Under the topic of psychology is included behaviorism, gestalt, and the 'laws of human nature.' The way these matters are taken up indicates that there are some students in Brazil who follow the American psychologists closely. The second part deals with special topics, first the psychic factors and secondly social life. The usual topics are considered here and even though the book is for South American consumption the topic of revolution is not overemphasized. The value of this book to medical men is obscure.

The Principles and Practice of Hygiene By Dean Franklin Smiley A.B. M.D. Professor of Hygiene in Cornell University. Adrian Gordon Gould Ph.B. M.D. Assistant Professor of Hygiene in Cornell University and Elizabeth Melby M.A. R.N. Assistant Professor Yale University School of Nursing. Second edition. Cloth. Price \$2.50. Pp. 495 with 96 illustrations. New York Macmillan Company 1935.

This useful textbook for nurses was first published in 1930. In the previous edition the authors limited their discussion to matters relating to personal and individual hygiene. In the new edition they have made little change but have simply added a section on community sanitation. They have not been successful in condensing this comprehensive subject within some seventy-eight pages. The major titles of the material that is considered are (1) water supplies and their purification, (2) prevention of food-borne infections, (3) combating the hazards of the lower animals, insects and soil, and (4) home sanitation. All these subjects are discussed inadequately, while much equally important material is given no consideration whatever. The chapter on combating the hazards of the lower animals, insects and soil is a heterogeneous mixture of subjects that have little interrelationship. The chapter on home sanitation is perhaps the least adequate of the group. It probably would have been more advantageous if the authors had written a separate book on the subject 'Community Sanitation' rather than attempt to abridge and condense this information within the pages of their original volume.

Anemias y alimentación El principio antianémico del hígado y los factores cualitativos de los alimentos (vitaminas, aminoácidos, hierro y cobre). Por José Sánchez Rodríguez. Tesis doctoral premiada por la Academia Nacional de Medicina en 1935. Prólogo de Gregorio Marañón. Paper. Price 12 pesetas. Pp. 170 with 22 illustrations. Madrid Cruz y Raya, 1935.

The book is divided into two parts, theoretical and experimental. In the first part the chemistry of the red blood corpuscle and the factors that control the level of hemoglobin are considered. Anemias are classified as being caused by (1) insufficiency (lack or defective utilization) of the nutritive materials (iron, amino acids), (2) changes in the hematopoietic organs (toxic, infectious, metabolic, mechanical), (3) alterations in the catabolism of the blood pigment (toxic hemolytic, infectious hemolytic) and (4) alterations in the regulating factors (antianemic principle of liver, hormones, vitamins, copper). The importance of alimentation in the cause and correction of anemia is stressed. In studying the composition of liver extract to throw light on the qualitative factor of the defective alimentation of the antianemic substance in pernicious anemia, Rodríguez used a European preparation of liver that apparently differed in many respects from the preparation in use in America. He found no appreciable amounts of iron, copper, hydroxyproline, beta-hydroxyglutamic acid, or vitamins A, B₂, C, D or E. The author therefore questions Strauss and Castle's suggestion that B₁₂ is the 'extrinsic factor' in the production of antianemic substance, and he also eliminates B₁₂ as a factor. Both of these he finds in gastric mucosa, although he found no B₁₂ in normal gastric secretion. The hematopoietically active principle of liver is considered as a definite vitamin. There is appended a bibliography of 502 articles, including a large number from American literature.

Annual Review of Biochemistry Edited by James Murray Luck. Stanford University. Volume IV. Cloth. Price \$5. Pp. 639. Stanford University California Annual Review of Biochemistry Ltd 1935.

This collection of reviews in fields of current interest to biochemists and to others who deal with biochemical problems is now in its fourth year. As in past volumes, investigators from many parts of the world have been chosen to prepare the material on the various subjects, thus this book is truly an international achievement, representing the efforts of thirty-two authors from eight countries. The subjects reviewed in volume IV include permeability, biologic oxidations and reductions, enzymes, chemistry of carbohydrates and glucosides, acyclic constituents of natural fats and oils, proteins and amino acids, sulfur compounds, nucleic acids, purines and pyrimidines, muscle and bacteria, metabolism of carbohydrates, fats, amino acids and proteins, creatine and creatinine, and of brain and nerve detoxication mechanisms, hormones, choline compounds, vitamins, nutrition, chemical embryology, biochemistry of malignant disease, plant pigments, alkaloids, mineral nutrition

of plants, growth substances of plants, immunochemistry To review in detail this vast amount of material is obviously not feasible It is inevitable that the different reviews should vary in quality, some are more critical than others Despite the shortcomings of a few of them, the book as a whole serves as an admirable introduction to and synthesis of current literature of biochemistry Although it would undoubtedly add considerably to the difficulty and cost of preparing these annual volumes, it appears that a subject index would greatly enhance their utility as reference books

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern Atlas der normalen Ossifikation der menschlichen Hand Von Prof Dr F Siebert Ergänzungsband XLVII Fortschritte auf dem Gebiete der Röntgenstrahlen Herausgegeben von Prof Dr Grashey Paper Price 16 marks Pp 43 with 158 illustrations Leipzig Georg Thieme 1935

This statistical study of the ossification of the hand is based on the author's extensive material and is illustrated by thirty-six excellent plates with 134 roentgenograms of normal hands of both sexes and sixteen roentgenograms of the hands of patients with various pathologic conditions The author concludes from his observations that ossification takes place earlier in female children than in male but that in both sexes the order of ossification is relatively uniform Ossification may be of different types in different families and this fact should be remembered in attempting to distinguish between normal and pathologic conditions In the author's judgment the tables of Adams showing the relation between the length and the weight of a child are preferable to those of Pirquet

Laboratory Methods of the United States Army Edited by James Stevens Simmons B S M D Ph D Major Medical Corps United States Army Associate Editor Cleon J Gentzkow M D Ph D Major Medical Corps United States Army Approved by the Surgeon General of the United States Army Fourth edition Fabrikoid Price \$6.50 Pp 1 091 with 70 illustrations Philadelphia Lea & Febiger 1935

Planned originally to aid medical officers during the World War this volume is now in its fourth edition, much revised and greatly enlarged In its development many competent workers have given their aid and services, and they are credited in the book for their contributions The present volume is a complete guide to laboratory methods in medicine, veterinary practice and statistics Its usefulness can hardly be exaggerated, since it represents the experience of workers handling thousands of specimens under conditions enabling suitable controls There is a competent index The tests and methods offered are those usually followed in army work, in many instances only a single method is given although several methods may be available Thus, there is but a single rough and ready method for blood coagulation and there does not appear to be any method described for counting blood platelets Wassermann and Kahn tests are given in great detail with complete theoretical considerations For the determination of blood sugar, the Folin-Wu method is described Notwithstanding its minor deficiencies, the work is still a *vade mecum* in the laboratory field

Ear Exostoses By Aleš Hrdlička Curator Division of Physical Anthropology U S National Museum Smithsonian Miscellaneous Collections Volume 93 number 6 Publication 3296 Paper Price 50 cents Pp 100 with 13 illustrations Washington D C Smithsonian Institution 1935

The subject of ear exostoses does not occupy a prominent place in otology Curiously enough, however, the names of a number of famous otologists are associated with studies of these peculiar formations For the anthropologist too they hold peculiar interest The author has written a monograph of more than academic interest He discusses this subject as completely as can be, with literature, observations old and new, and the detailed data as to the age, sex, frequency of the occurrence, and etiology, and in a general discussion sums up the available information He concludes that exostoses of the ear are abnormalities rather than a disease, arising from the free ends of the tympanic ring They occur chiefly in later adolescence and early adult life They are seen in all races The otologist whose interest in things concerning the ear is not limited to the happenings of everyday practice will find this authoritative monograph absorbing reading

Incompatibilités pharmaceutiques Par le Prof A Goris directeur de la pharmacie centrale des hôpitaux et A Liot adjoint au directeur de la pharmacie centrale des hôpitaux Paper Pp 140 with 4 illustrations Paris Librairie E Le François 1935

The authors are right in their idea that it is time a newer book on incompatibilities was written, as the only two little books on the subject (Ruddiman's of 1908 and Hagers' of 1907) are now quite out of date One looks in vain in those relatively old books for information on the incompatibilities of many of the extensively used newer remedies For the French reading physician therefore this book will "fill a long felt want" An English book on incompatibilities is just about due

Medicolegal

Malpractice Negligent Treatment of Fracture—The plaintiff fractured both bones of his right forearm The defendant reduced the fractures, using only one splint The bones did not stay in alignment and three times successively within a week the defendant attempted a resetting, each time using only one splint A substantial permanent deformity and loss of function of the arm resulted and the plaintiff sued the defendant, obtaining judgment in the trial court The defendant appealed to the Supreme Court of Minnesota.

The whole issue, said the Supreme Court, was whether, in connection with the splint he did use, the defendant should have applied another or posterior splint to keep the bones in place The failure to use the second splint was improper practice, according to the medical testimony for the plaintiff The defendant was not a very good witness for himself, the court said When asked what made the bones "slip all the time," his answer was "I don't know" He testified that the use of a posterior splint "might have held the bones in proper alignment, yet he insisted that he was "proud of this job" The Supreme Court said that the evidence presented a *jury question* and the court could find from the record no ground on which it could properly interfere The judgment for the plaintiff was consequently affirmed.—*Citrouski v Libert (Minn)*, 260 N W 297

Workmen's Compensation Acts Traumatic Rupture of Diseased Appendix Compensable—The employee, during the course of his employment, assisted two fellow employees in carrying a heavy beam up a steep incline He slipped and fell to his knees and immediately complained of abdominal pain, which persisted and forced him to quit work An abdominal operation performed about thirty-three hours after the accident disclosed a diseased appendix and peritonitis, with the abdomen "filled with pus" No perforation was located, but an extensive exploration was not done because of the patient's grave condition The appendix was removed and drainage instituted, but the employee died seven days after the operation The department of labor and industries denied the claim of the employee's wife for an industrial insurance pension under the workmen's compensation act of Washington, and, from a judgment of the superior court sustaining the department's disallowance, the claimant appealed to the Supreme Court of Washington.

The operating physician stated the causes of death in the death certificate, as follows "The remote cause of death Accidental injury The immediate cause of death Peritonitis and infection causing obstruction also traumatic appendicitis" An autopsy proved to be of little or no value in locating a possible perforation because of the extent to which the peritonitis had progressed by the time of death and because the embalmer had removed the gas and fluid from the abdominal viscera It seems to have been conceded that prior to the accident the employee had a painless chronic inflammation of his appendix The operating surgeon testified that trauma may accelerate chronic appendicitis and cause a rupture or perforation of a weakened diseased appendix He expressed definitely the opinion that the injury received was the real beginning of the condition which caused the death of the employee While the evidence was clear, the court said, that the appendix was diseased and in the course of time would

have ruptured without any external pressure, yet there was evidence that the rupture of the appendix was accelerated by the injury. In view of this evidence, said the court, a rule laid down in *Shadbolt v Department of Labor and Industries*, 121 Wash 409, 209 P 683, applies.

Even though the appendix was diseased and in course of time would have ruptured without any external pressure if its rupture was accelerated by such pressure this would constitute an injury.

In the opinion of the Supreme Court, the claimant sustained the burden of proof that the accident suffered by the employee caused or accelerated a rupture of the appendix or intestine and that his death resulted therefrom. The judgment of the superior court was reversed, therefore, with direction to remand the case to the department of labor and industries with instructions to allow the claim.—*Thomas v Department of Labor and Industries* (Wash.) 44 P (2d) 765

Malpractice Facial Paralysis Following Mastoidectomy—The physician-defendant, a specialist in diseases of the ear, nose and throat, punctured the plaintiff's ear drum from which pus was immediately discharged. After observing the patient for four days he made a diagnosis of mastoiditis and performed a mastoidectomy. The operation resulted in a degree of facial paralysis. Another physician who performed a second operation to alleviate the paralysis found that the facial nerve had been injured. This operation improved the facial paralysis, but return of function was not complete. The plaintiff then sued the physician-defendant. From a judgment against him, the physician-defendant appealed to the Supreme Court of Washington.

The physician-defendant contended that he was not negligent in performing the operation but that during the operation the facial nerve was exposed, as the result of necrosis of the protecting bone, and somehow subjected to injury. Such necrosis, he said, could set in within four days after the onset of infection. The plaintiff argued that infection had not existed for a sufficient time to cause such necrosis and that if the operation had been performed skillfully the facial nerve would not have been injured. The physician who performed the second operation testified that two weeks to a month in an average case of mastoiditis, and never less than eight days, was required for an infection in the middle ear to spread into the mastoid and produce the necrosis in question. The plaintiff testified that the physician-defendant told her that he had made a mistake and had cut the nerve saying nothing at the time about any necrosis or crumbling of the bone. The physician-defendant denied having made this statement and testified 'I told her that during the operation I had accidentally uncovered the facial nerve and that I did the best I could under the circumstances I had to deal with and that was what had happened.' There was sufficient evidence said the Supreme Court to justify the jury in finding that the time between the detection of infection and the operation was insufficient for such necrosis to have set in. It was not contended that the physician-defendant adopted an erroneous method of operating or that the operation which he performed was not proper and necessary. The contention was that the operation was performed in a negligent manner. The distinction between the two classes of cases involving negligence on the part of physicians is pointed out in *Swanson v Hood* 99 Wash 506 170 P 135 wherein it was said:

But there is an obvious distinction between a claim of negligence in the choice of methods of treatment and a charge of negligence in the actual performance of the work or treatment after such choice is made. As to the first the charge is refuted as a matter of law by showing that a respectable minority of expert physicians approved of the method selected thus taking the case from the jury. As to the second a charge of negligent performance where there is any evidence tending to show such negligence the case is for the jury as in other cases of negligence whenever upon the evidence the minds of reasonable men might differ.

The record in the present case said the Supreme Court contains substantial evidence to support the jury's finding that the operation was negligently performed. There was no testimony to the effect that in operations similar to the one here involved the facial nerve is frequently injured. The evidence went no further than to indicate that such injuries occasionally occur. The plaintiff was not required to prove negligence by

direct and positive evidence. It was only necessary that a chain of circumstances be established from which negligence was reasonably and naturally inferable. The jury had a right to take into consideration the fact that a second operation was necessary in order to correct the condition resulting from the first operation.

The Supreme Court could find no reversible error and therefore affirmed the judgment of the trial court for the plaintiff.—*Marlowe v Patrick* (Wash.), 44 P (2d) 776

Malpractice Roentgen Burns, Accrual of Right of Action—The plaintiff in 1928 sustained a roentgen burn as a result of treatments administered by the defendant, for the purpose of preventing conception. According to the complaint, the physician minimized the severity of the burn and continued to attend the patient until 1932, when, the burn having gradually become worse, he suggested that she seek relief from another physician. Claiming permanent injury as a result of the burn the patient and her husband in 1934 sued the defendant. The trial court sustained the defendant's demurrer to the complaint, on the ground that the suit was barred by the three year statute of limitations. The plaintiffs thereupon appealed to the Supreme Court of Washington.

In Washington, said the court it has been held in several malpractice cases arising against attorneys that the cause of action is founded on a breach of duty arising out of contract and that the three year statute of limitations is applicable. In the present case, six years elapsed between the infliction of the burn and the commencement of suit. The plaintiff contended, however, that her action was not barred by the statute of limitations because (1) the defendant fraudulently concealed from her the severity of the burn, and (2) the statute did not begin to run until 1932, when the defendant's professional services were terminated. With respect to the first contention, the Supreme Court said that the decision in the case of *Cornell v Edson* 78 Wash 662 139 P 602, was controlling. In that case, wherein it was alleged that an attorney had wrongfully dismissed an action and had concealed that fact from his client, it was urged that the concealment tolled the statute of limitations. In holding to the contrary, the court in that case said, in part:

The action is plainly one based upon a breach of duty growing out of the relation existing between the parties a contractual relation which calls for a full disclosure and when by reason of the failure to make a full and complete disclosure or the withholding or concealment of facts which should have been disclosed loss is suffered there is a breach of duty and for such breach an action will lie. But like any other action founded upon a breach of duty imposed either by law or contract the action arises out of the breach and the statute of limitations begins to run from the time of the breach and not from the time of its discovery.

In this case the duty is one growing out of the relation between the parties and that relation is one based upon contract. The relation it is true is fiduciary, but that does not disturb the fact that it is contractual and that a cause of action based upon the breach of the contract accrues when the contract is violated and not when the violation is discovered.

With respect to the contention that the statute of limitations did not begin to run until after the defendant discontinued his services, the court again referred to a prior decision, *Jones v Gregory* 125 Wash 46, 215 P 63. In that case the plaintiff alleging that she suffered loss by the negligence of her attorneys contended that the statute of limitations did not begin to run until the services of the attorneys had ceased. In disposing of that contention, the court said:

The contention made in appellant's behalf seems to be that in some way the starting of the running of the statute was stayed by the efforts put forth by respondents as counsel for appellant looking to the setting aside of the original decree of distribution and the entering of another decree of distribution awarding to her all of the property of the estate. We are quite at a loss to understand how such action on the part of respondents or how such subsequent proceedings in court, looking to the setting aside of the original decree of distribution could stay the starting of the three year statute of limitations. Surely whatever respondents did resulting in damage to appellant occurred not later than the entering of the decree of distribution on December 4, 1918. Manifestly appellant's right of action if any she ever had accrued not later than that date. Every act of respondents which could possibly have resulted in the damage claimed to have been suffered by appellant was committed before or upon that date.

In the *Jones* case the Supreme Court pointed out the attorneys, after making their mistake, endeavored to correct it, in

the present case, after the act of malpractice, the defendant continued to treat the plaintiff in an effort to alleviate and correct his first mistake. The gravamen of the present action is the defendant's malpractice in the performance of the service for which he was originally employed. It would be trifling with the facts, the court said, to say that the present action was brought, not for the original injury, but for the defendant's subsequent failure to correct the original wrong. Numerous authorities cited by the plaintiff to support her position related generally to cases in which the physician's employment had relation to an existing injury or malady which the physician was called to treat. In the present case, the court said, the defendant's original employment by the plaintiff was not to cure the roentgen burn but to prevent conception. The defendant's breach of duty to the plaintiff consisted in the negligent manner of his treatment to effect this purpose, and this is the wrong for which the plaintiff seeks recovery.

The Supreme Court therefore concluded that the trial court correctly sustained the defendant's demurrer, and the judgment of dismissal was affirmed—*McCoy v Stevens (Wash)*, 44 P (2d) 797

Hospitals Operation of a Municipal Hospital a Governmental Function—The defendant city of McAllen owned and operated a hospital, supplying hospital care to all persons within the city who were in need of it and charging a fee only to those who were able to pay. The hospital was built by means of a city bond issue and was operated as a part of the city government. The plaintiff, a pay patient, was injured as the result of the negligence of a student nurse employed by the hospital. The plaintiff and her husband sued the defendant city and its insurance carrier. From a judgment in favor of the plaintiff, the city and its insurance carrier appealed to the court of civil appeals of Texas.

A hospital, said the court, constructed and maintained by a city for the principal purpose of conserving the public health, as was the defendant hospital, receiving indigent patients without charge, and applying all money received to expenses, is a charitable institution and is not liable to a pay patient for injuries due to the negligence of an employee. Furthermore, the defendant city operated the hospital in the performance of a governmental function and consequently was not for that reason liable in the present case. Accordingly, the court reversed the judgment of the trial court for the plaintiff—*City of McAllen v Gartman (Texas)* 81 S W (2d) 147

Optometry Corporate Practice of Optometry Illegal, Injunction to Restrain Practice—The two cases here abstracted hold that corporations may not lawfully practice optometry.

In New York, the Secretary of State refused to accept for filing a proposed certificate of incorporation whereby the corporation was to be authorized, among other things, "to transact and carry on the optical business, to do render and perform optometrical and oculists' work and services and to engage in the practice of optometry, provided it employs only licensed optometrists to do the work." The plaintiff instituted proceedings in the supreme court of New York to compel the Secretary of State to accept for filing the proffered certificate. The defendant Secretary of State contended that a corporation may not be lawfully formed to practice optometry or to perform "oculists' work and services," even though it employs licensed optometrists to do the work. With this contention, the supreme court agreed. In *Matter of Co-operative Law Co*, 198 N Y 479, 92 N E 15, it was held that a corporation may not lawfully practice law in New York. In *People v John H Woodbury Dermatological Institute*, 109 N Y S 578 85 N E 697, it was held that it was against the policy of the state to permit corporations to practice medicine. Likewise, in *Hannon v Siegel-Cooper Co*, 167 N Y 244, 60 N E 597, it was held that a corporation cannot lawfully practice dentistry in New York by employing a licensed dentist to do the work. If, said the supreme court, it is repugnant to the policy of the state to have the professions of medicine, dentistry and law practiced by a corporation, it is equally repugnant to have the profession of optometry practiced by a corporation. The practice of optometry the court pointed out, may be carried on only by

those persons who have complied with the requirements of the statute regulating the practice of optometry as to moral character and educational fitness. It necessarily follows that the right to practice optometry is a personal one and confined to real persons and not to legal entities. A corporation as such cannot meet the requirements of the statute, it cannot have completed a course in a high school or in a university where optometry is taught, it cannot present the necessary certificate of character, it cannot pass a state board examination. In denying the plaintiff's petition, the supreme court concluded

The proposed certificate of incorporation provides for the carrying on of the optical business and the rendition and performance of optometrical and oculists' work and services. A corporation is forbidden both by statute and judicial decisions from performing an oculist's work and services, an oculist being a duly licensed physician specializing in the diseases of the eye. While this motion could well be denied on the ground that a corporation may not render oculists' services I have been requested to base this decision on the question of whether or not a corporation may be organized for the purpose of practicing optometry. I hold that it cannot lawfully be organized for such purpose.

In West Virginia, two licensed optometrists, suing on behalf of themselves and all others similarly situated, obtained an injunction against the defendants, the Buhl Optical Co, a corporation, and the O J Morrison Department Store Company, another corporation, prohibiting them from practicing optometry through registered and licensed optometrists. The defendants appealed to the Supreme Court of Appeals of West Virginia.

The defendant optical company maintained an optometry department in the defendant department store, in charge of a licensed optometrist paid by the optical company. A fixed percentage of the gross receipts from this department went to the department store, the remainder went to the optical company. The optometry practice act, said the court, recognizes optometry as a profession and provides that it shall be unlawful for any person to practice optometry in the state who has not been licensed and registered. It requires that applicants shall have attained the age of 21 years, shall be of good moral character and temperate habits, and shall pass specified educational qualifications. A licensee is forbidden to advertise, practice or attempt to practice "under a name other than" his own. This prohibition, the court said, is certainly antagonistic to the view that a corporation may practice optometry through a licensed optometrist. In holding that a corporation could not lawfully engage in the practice of optometry in West Virginia, the court cited with approval the New York case abstracted above. In a specially concurring opinion, Judge Maxwell said

The act precludes all persons not properly registered from practicing optometry. A corporation is a person and in the nature of things it cannot possess the qualifications to practice optometry. A person, individual or corporate may not do by indirection what he or it is precluded from doing directly.

The decree of the trial court, granting the injunction, was therefore affirmed—*Stern v Flynn (N Y)*, 278 N Y S 598
Eisensmith v Buhl Optical Co (W Va), 178 S E 695

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Tumors of Peripheral Nerves C. F. Geschickter Baltimore—p. 377

Dysontogenetic Origin of Basal Cell Carcinoma—

McFarland and his collaborators plotted a number of carefully selected and histologically confirmed cases of basal cell carcinomas from two hospitals on two diagrams of the face in order that their distribution might be studied with reference to their possible dysontogenetic origin through defective concurrence of the embryonal facial fissures as suggested by Glasunow. The observations have been compared with the plottings of other supposed dysontogenetic lesions, sequestration dermoids and mixed tumors, with the result that all three types of lesions are found to conform to about the same anatomic distribution, which is entirely different from that of the more common squamous cell or prickle cell carcinomas. The authors do not believe that their observations settle the question but they do believe that they support the theory of Glasunow that the basal cell carcinomas are dysontogenetic tumors which originate in imperfections in the closure of the embryonal facial fissures.

Artificial Fever as Means of Destroying Cancer—

Walker found that tumor 256, a scirrhous carcinoma of the mammary gland, was destroyed in vitro at a temperature of 111.4 F. His experiments on the living animal show that if it were possible to raise the temperature of a tumor-bearing rat up to 111.4 F. and to maintain it at that point for twenty minutes, all the malignant tissues throughout the body could be destroyed. Up to the present, however, exposure to this temperature has proved uniformly fatal. Raising the temperature to 109 F. at repeated intervals does not destroy the tumor nor does it seem to retard the growth. The artificial fever produced by the high frequency apparatus appears to be more damaging than the artificial fever produced by the thermostat. There seems to be something especially injurious in the high frequency

method, for in no instance did the animal live as long as the required twenty minutes after the temperature reached 111.4 F. The construction of a large thermostat, in which it would be possible to maintain a temperature of 100 F. with complete saturation of the air with water vapor, might offer a safer method of producing artificial fever than the use of the high frequency apparatus.

Changes in Technic of Kolmer-Wassermann Test—

Kolmer states that the amounts of serum employed in the Kolmer quantitative complement fixation test for syphilis have been changed to 0.2, 0.1, 0.05, 0.025 and 0.005 cc. with 0.2 cc. in the serum control. In the qualitative test the amounts have been changed to 0.2 and 0.1 cc. with 0.2 cc. in the serum control. By using a first dose of 0.2 cc. of serum, the sensitiveness of the reactions has been increased without any increase of nonspecific reactions. The antigen has been improved by reinforcing with acetone-insoluble lipoids. It is used in a dose of 20 instead of 10 antigenic units, which increases the sensitiveness of the reactions while preserving specificity and freedom from falsely positive reactions, the test is otherwise conducted exactly as described originally.

Differential Diagnosis of Enlargement of Cervical

Lymph Nodes—Farquharson states that the diagnosis of enlargement of cervical lymph nodes is usually made without difficulty on the history and the clinical and hematologic examination alone. Of the swellings affecting only cervical lymph nodes difficulty is sometimes found in differentiating certain cases of tuberculous adenitis from lymphosarcoma and early Hodgkin's disease. A biopsy is often helpful in these circumstances but the histologic picture is not always decisive and then the diagnosis may be determined only by the subsequent course of the disease. In patients with generalized involvement

of the lymph nodes one must be careful not to confuse infectious mononucleosis, which is never serious, with acute leukemia, which is always fatal. The differentiation is clearly made by clinical examination and study of the blood picture. The importance of history and clinical examination with a consideration of the blood picture is stressed. The information obtained by histologic examination of the excised gland is often useful but sometimes indeterminate and occasionally misleading. It should be considered together with all the clinical data in the final summing up of difficult cases.

Short Wave Therapy in Pyogenic Skin Infections.—De Chohnoky presents six cases that give a clear picture of the effectiveness of short wave therapy in promoting the healing of furuncles. He has gained the impression that the conservative treatment of furuncles with the aid of short wave therapy is a decided advance over methods employed heretofore. It is a simple method with no attendant dangers and in most cases renders surgery unnecessary. Nevertheless, in appropriate cases it may be necessary to make a small incision in order to hasten the healing process and facilitate evacuation. In his thirty-seven cases of furuncle it was necessary to incise only twice. These were instances in which abscess formation was present which inconvenienced the patient by its size or location. When surgery is employed in conjunction with short wave therapy, it shortens the time of recovery. The author also employed short wave therapy in carbuncles, axillary sweat gland infection and abscesses, erysipelas and erysipeloid. The treatment terminates with good cosmetic results.

Pathogenesis of Fibro-Adenosarcoma of Breast.—Grauer and Robinson state that the correlation of their experimental observations with the clinical observations establishes fibro-adenosarcoma as a definite clinicopathologic entity and apparently explains the pathogenesis of this type of neoplasm of the breast. The suggestion that this tumor be considered an adenofibrosarcoma is a logical one for it is a generic as well as a

descriptive term. Although the term sarcoma implies a highly malignant condition which is not observed in this particular tumor, one must necessarily employ it because of the fibrous nature of the tumor. This raises the point concerning the character of the fibrous tissue which is found immediately around the acini and from which it appears that this tumor arises. The periacinal fibrous tissue is of a looser texture and more embryonic in appearance. Owing to some unexplained factors it overgrows the epithelial elements and produces the alterations in the character of the tumor that were observed in the various transplants. The newer interpretation of the production of various abnormalities of the breast as being an expression of hormone activity appears logical to the authors, but they are reluctant to consider a definite neoplasm, such as fibro-adenoma, as being merely an area of abnormal involution. They consider this especially true since they demonstrated that an adenofibroma of the breast will continue to grow indefinitely during transplantation, whereas breast tissue when transplanted exhibits no neoplastic characteristics.

Fibro-Adenoma of the Breast During Pregnancy.—Moran observed twenty-seven fibro-adenomas removed during pregnancy and lactation or present during that period and removed at varying intervals following the cessation of lactation. The tumors were modified by pregnancy and lactation and the changes produced in them were similar to those occurring simultaneously in the surrounding normal breast. The endocrine factors involved in the development and function of the breast are chiefly discussed, and it is suggested that the changes observed both in the breast and in the fibro adenoma are of hormone origin.

Osteoid-Osteoma.—Jaffe presents clinical, roentgenologic and pathologic details concerning five cases of a peculiar bone neoplasm. He denotes this lesion osteoid osteoma and considers it as a distinctive, not heretofore classified, type of bone neoplasm. It is a benign osteoblastic tumor composed of osteoid and atypical bone. In the cases seen it always arose intramedullary in spongy areas. The patients were either adolescents or young adults. The principal complaint was of local pain. As observed by roentgenogram, the pathologic areas were roundish and rather small. Complete eradication resulted in the eventual disappearance of all symptoms. The lesion had no features suggesting an inflammatory origin or origin from an embryonic rest or that it represented an unfamiliar healing stage of a giant cell tumor, localized osteitis fibrosa or cyst. Despite the fact that the lesion of osteoid-osteoma remained small and globuloid in these five cases, the character of the pathologic tissue in the more diffuse tumor previously described by Mayer and the author suggests to him that the latter lesion may be related to the type of tumor under discussion. It also seems likely that the lesion described by Bergstrand as being of embryonic origin and which he regarded as neither an inflammatory process nor a tumor is likewise related to osteoid osteoma.

Hypothyroid Heart Disease.—Brittingham cites the case of a person with typical clinical, roentgenographic and electrocardiographic manifestations of "myxedematous heart disease," who became normal under thyroid therapy. The characteristic manifestations of this condition are described and attention is called to the dangers of too rapid or uncontrolled thyroid

administration The author believes that this type of cardiac abnormality is more common than is supposed and that cardiograms taken of all hypothyroid individuals will add many more cases to those already reported He has seen the condition in three patients in the last five years

Subacute Streptococcus Viridans Septicemia—Hamman and Rienhoff discuss the examination and diagnosis of a young man who had been febrile for six months The observations demonstrated that the patient was ill with *Streptococcus viridans* septicemia, but it was not clear where the infection was located The long duration of the illness, the persisting fever, the anemia the enlargement of the spleen and the repeatedly positive blood cultures demonstrated that there must be a locus of infection having direct access to the blood stream and continuously discharging bacteria into it The anticipated evidence of a valvular defect was completely wanting The heart sounds were clear and of normal quality, except that there was a systolic murmur at the pulmonary urea Being convinced by repeated examinations that the infection was not located on the heart valves, the authors considered two possibilities that the vegetations were on the endocardial surface of the chambers of the heart or that they were situated within the arteriovenous aneurysm Investigation led the authors to believe that in all probability *Streptococcus viridans* had settled and grown within the arteriovenous aneurysm and from this site of advantage was continuously pouring bacteria directly into the blood stream Should this be the case, the septicemia might be cured and the patient restored to health by excision of the aneurysm The specimen removed at operation measured 85 cm in length and consisted of a portion of the external iliac artery and vein, a portion of the common iliac vein and surrounding connective tissue and fat After the wound had been dressed it was apparent that the circulation in the right leg was defective, for the skin was cold and mottled by areas of cyanosis During the operation the leg had been elevated above the level of the heart The patient was adjusted in the recovery bed so that the leg was held level with the heart and was surrounded with hot water bottles At the end of an hour the circulation had improved greatly and the temperature of the skin had risen to a point a little above normal The skin was then a bright pink and the areas of cyanosis had disappeared As vascular tone returned the color of the skin became normal and the edema disappeared From then on the patient's recovery was uneventful Four months after operation the patient had gained 40 pounds (18 Kg), had an excellent color and was a picture of robust health He had been working steadily for a month at first for half a day, but during the previous week for seven hours He walked about without any support and complained only of a little pain in the leg if he walked too far At the end of the day there was a little swelling about the ankle which disappeared during the night The pulse rate was 76 The

right leg was normal in appearance The right thigh and calf measured 1 cm. more than the left No pulsation could be felt in the right femoral artery or in any other arteries of the leg

Estimation of Bacterial Content of Mouth—With the aim of separating the clumps of bacteria, due to mucin and epithelial cells in the saliva and to the thread forms which entangle masses of bacteria, Crowley and Rickert employed a method similar to that used by Breed and Brew (1933) for making direct bacterial counts of milk, with the exception that an atomizer was used to break up the larger masses and a very dilute sodium hydroxide solution was used as a diluent to dissolve the mucin They found that the difference in counts made by this method is 13 per cent The number of bacteria in sprayed washings increased appreciably (at least 36 per cent) over the unsprayed material Four hundred normal sodium hydroxide treated washings gave a better distribution of bacteria in a smear without, however, materially increasing the count Counts taken at different times of the day and on different days varied greatly in the same individual No correlation was noted between counts made by the method described and the "diurnal tide" of Feirer and Leonard

New Method for Determination of Minute Amounts of Lead in Urine—Ross and Lucas report a microcolorimetric method for the determination of small amounts of lead in urine

The method is applicable for use in a clinical laboratory, since the time required for a determination is reduced to three hours. The procedure may be readily applied to the urine of young children when only small samples are available.

Calcium Determination in Biologic Material—Wang states that a new washing solution for calcium oxalate precipitation of 2 per cent ammonia in equal parts of alcohol, ether and water prevents flotation and permits washing of the precipitate without appreciable loss of calcium. The treatment of urine with trichloroacetic acid and carbon allows direct calcium determination on urine.

Mycosis of Vertebral Column—Meyer and Gall review the reports of forty-seven cases of actinomycosis, twelve cases of blastomycosis and one case of sporotrichosis of the vertebral column. The infection of the vertebrae is most often found to be secondary, with a primary focus of infection situated principally in the respiratory and digestive tracts. The vertebrae are infected either by direct contact with a suppurating focus, in which case the external surfaces of the vertebrae are eroded, or by vascular metastasis, in which the bone destruction is found to be central and surrounded by a condensed ring of bone. The first possibility appears to be most frequently the case in actinomycosis, the second in blastomycosis. The differential diagnosis of mycosis of the vertebrae and Pott's disease, for which the former is usually mistaken, is to be made chiefly on the following grounds: 1. The angular deformity is most often absent in mycosis. 2. Mycosis shows multiple sinuses, more destructive invasion and a more rapid opening of abscesses than in Pott's disease, the skin lesions in mycosis are characteristic. 3. Roentgen examination shows erosion of the cortical portion of the vertebra, erosion that is present on the articular processes and pedicles as well as on the vertebral body, or cavity formation in the cancellous portion, surrounded by a zone of increased density. None of these signs are ordinarily seen in tuberculous spondylitis. The bony rarefaction of the latter disease sometimes gives place to a dense appearance in mycosis. One of the factors in the high mortality rate of mycosis of the vertebral column appears to be the difficulty in making an early clinical diagnosis.

Regrowth of Bone at Proximal End of Radius Following Resection—Surgical resection of a fractured or dislocated proximal portion of the radius may be complicated by the regeneration of a "new head of the radius," as Sutor noted in the four cases that he reports. This eventuates most probably from the accumulation and organization of blood in the space left by the surgical resection of the head of the radius with or without excision of the neck. The marrow spaces of the long tubular bones contain tissue with osteogenic potentialities, and it apparently makes its way into the adjoining organized hemorrhage. Furthermore, the periosteum of the radius adjacent to the resected area, as well as the tissue of the joint capsule, apparently participates in the formation of this bone. Most of the newly formed trabeculae, which result in an increase in the length and width of the proximal end of the radius, are formed by osteoblastic activity as well as by metaplasia of the contiguous fibrous tissues. Some of the recently formed fibrous bone is soon transformed into adult bone. The "new head of the radius" may present a cortex and a medullary canal. However, it lacks hyaline articular cartilage. The proximal surface of the "new radial head" may be capped either by fibrocartilage or by fibrous tissue. This is most probably derived from the capsular tissue about the joint. The formation of bone at the site of the resection of the original head of the radius may lead to an unusual lengthening of the shaft of the radius when compared with the normal opposite radius. In cases in which surgical removal of the proximal portion of the radius is necessary, a reconstruction operation should be attempted, fascia lata being used to prevent abnormal growth of the stump. The periosteum on the proximal (free) end of the shaft of the radius should be stripped back, all bone fragments, periosteal strips or capsular tissue, either lying free in the joint or loosely attached to contiguous tissues, should be removed. In addition, if an unusually large segment of the proximal portion of the original radius is resected, the gap should be filled by a bone graft.

Recovery of Function of Hand in Arthritis—Kuhns states that improvement in the function of the hand crippled by arthritis is possible, no matter how severe the disability. Prevention of deformity in chronic arthritis is much easier and gives a better end result than correction of deformity after the arthritis becomes quiescent. Deformity can be prevented by careful supervision and frequent splinting. The treatment for rehabilitation of the hand can be divided into three stages. The first, when deformity can be corrected passively, splints, exercises and heat will usually correct the deformity. The measures are carried out simultaneously with the treatment of the patient for the chronic arthritis. In the second stage, when deformity cannot be corrected passively and definite bony ankylosis is not present, more active measures, such as manipulations and constant traction should be added. The third stage of operative correction of deformity should be undertaken only in cases of quiescent arthritis. Surgical procedures should be performed on the hand only after an appraisal of the functional status of the whole arm and with due regard to the functional need of the individual patient.

Neglected Factor in Etiology of Gout—Krafka points out that any condition which tends to stimulate the erythropoietic system becomes an important factor in the overproduction of uric acid and thus a potential etiologic agent in gout. He presents two cases, the results of which are thoroughly in accord with his hypothesis and follow in logical sequence—marrow stimulation, overproduction of uric acid, gout. Another phenomenon, which has heretofore been obscure, is the association of the "gouty diathesis" with polycythemia. The obscure relationship between gout and lead poisoning loses much of its mystery when it is remembered that lead is a very active hemolytic agent and that every low blood count is compensated by an increased marrow activity. The author states that the spontaneity, the afebrile character and the tendency to become polyarticular all fit in with his hypothesis. Marked uric acid outputs have occurred in experimental animals immediately after hemorrhage or hemolysis, reaching a peak in about three days. He explains the disappearance of the old fashioned gout of a hundred years ago on the basis of the discontinuance of the medical practice of "bleeding," since even small hemo-

rhages are marked hematopoietic stimuli. By directing attention to the principal source of the offending agent, uric acid, a more satisfactory treatment of gout is possible. All hemolytic and hematopoietic agents should be used with discretion. In determining whether or not such agents are indicated, the normal reticulocyte count of 0.5 per cent should be the guiding factor.

Immunologic Studies with Virus of Influenza—According to Francis and Magill, following infection with the virus of influenza both ferrets and mice develop a state of active immunity to reinfection. The serum of these animals contains neutralizing antibodies, as evidenced by the capacity of the serum to confer passive protection to mice against infection with the Puerto Rico 8 and Philadelphia strains of the virus of human influenza. Rabbits apparently insusceptible to infection with the virus of influenza produce specific antibodies in response to repeated injection of virus-containing material. The serum of immunized rabbits affords passive protection to mice against mouse virulent virus. Although the subcutaneous or intraperitoneal injection of the living virus does not produce infection in mice, animals so treated acquire active immunity against subse-

quent infection by the intranasal route. Neutralization tests with the serum of patients before and after recovery from influenza pneumonia and the common cold indicate that neutralizing antibodies arise as a specific response to infection with the virus of influenza. The immunologic identity of strains of influenza virus recovered from human sources has been established and the possible existence of strains of related, but not identical, antigenic structure is discussed.

Bile Fistulas and Related Abnormalities—Hawkins and Whipple state that it is not easy to keep a bile fistula dog in a normal state for months if proper attention is given to the diet and physical condition. The most significant abnormalities are intestinal disturbances, spontaneous bleeding, osteoporosis, cholelithiasis and duodenal ulcer. They used three types of bile fistula in their experiments, and each one has its advantages and disadvantages. Intestinal intoxication is best controlled by diet, whole bile or bile salts or combinations of dog and ox bile. Spontaneous bleeding seems to be due to the loss of something by way of the bile, and this can be prevented by bile feeding. The blood deficiency appears to be a lack of prothrombin. Osteoporosis appears inevitably after many months if bile is excluded from the intestine. This state is related to the lack of absorption of vitamin D. It is of some interest that liver feeding will prevent it. Duodenal ulcers and cholelithiasis are common in bile fistula dogs and absolute control or prevention is not easy. Bile secretion into the intestine is necessary for normal health and even for actual continuation of life beyond a period of a few months. The authors believe that some of these experimental data should be of value to physicians and surgeons in the care and study of human fistula cases and should emphasize the necessity of prompt dietary control.

Response to Intracutaneous Injections of Pneumococcus Polysaccharides—Finland and Dowling elicited immediate cutaneous reactions, similar to those described by Tillett and Francis, in patients recovering from pneumonia. These reactions were, in general, type specific and were associated with the homologous type antibody in the serum. Very similar reactions were elicited with preparations of soluble specific substances and cellular carbohydrates prepared from the same pneumococcus types by the methods of Heidelberger, Goebel and Avery and those of Wadsworth and Brown. Characteristic delayed reactions were seen only with the cellular carbohydrates. These were not associated with type specific antibodies. They were most frequently observed with the cellular carbohydrates of the atypical type I pneumococcus and with that obtained from the virulent type I strain. Delayed cutaneous reactions with the cellular carbohydrate of an atypical type I pneumococcus were obtained regularly during the febrile stage of a variety of infectious disease and could not be elicited soon after recovery in such cases. These observations are similar to those obtained by Francis and Abernethy with the C substance of Tillett, Goebel and Avery. All the type specific polysaccharides were antigenically active in human subjects. They produced in almost every instance a strictly specific antibody response. Only minor differences were observed with the different preparations of types II and III polysaccharides. The type I cellular carbohydrate however was quantitatively more active than the corresponding SSS in this respect. Occasional subjects showed specific antibodies, particularly against type I pneumococci, following injections of the atypical cellular carbohydrate.

Study of Dextrose and Sucrose Tolerance Tests—

Schmidt and his co-workers made a comparative study of the blood sugar curves and sugar excretion, if any, on a series of fifty-seven hospital patients after the ingestion of dextrose, followed a few days later by an equal quantity of sucrose, or vice versa. With one exception these patients were admitted for conditions other than diabetes and only through tolerance studies were the diabetic tendencies discovered. A group of eighteen patients, free from obvious carbohydrate metabolism abnormalities, gave normal blood sugar curves and urines negative to Benedict's solution with both sugars. The average blood sugar curve given by the sucrose meal was 1151, 1271 and 275 per cent lower than that given by dextrose for the one-hour, two-hour and three-hour periods. Therefore the ingestion of approximately 100 Gm of sucrose ordinarily yields a blood sugar curve well within the normal limits as established by dextrose tolerance tests. The urines were free from sucrose or reducing sugars, regardless of the type of sugar ingested. Twelve patients with diabetes mellitus showed marked hyperglycemia and glycosuria with both sugars. The average blood sugar values for these sucrose tolerance tests were 118, 225, 3, 184 and 1496 mg per hundred cubic centimeters for the fasting, one-hour, two-hour and three-hour periods, as compared to 1178, 2478, 2226 and 185 mg for dextrose at the respective time intervals. Both sugars resulted in glycosuria to approximately the same extent. In no case did the administration of sucrose fail to bring out the diabetic tendencies of these patients. Clinically, sucrose is as satisfactory as dextrose for the detection and evaluation of diabetes mellitus. Twenty-seven patients with various arthritic and infectious conditions have also been studied in a like manner. The average blood sugar values following sucrose ingestion were 1039, 1834, 1604 and 1237 mg per hundred cubic centimeters for the fasting, one-hour, two-hour and three-hour periods, as compared to 1037, 1983, 1738 and 1369 mg for dextrose at similar time intervals. Sucrose tolerance tests as well as dextrose tolerance tests show that an abnormality in carbohydrate metabolism is present during arthritis, infections and similar conditions. In addition, sucrose ingestion shows equally well that this abnormality disappears as the infection clears up. Despite the high values for the blood sugars, the urines were usually free from reducing sugars. Glycosuria was present during six dextrose tolerance tests and during two sucrose tolerance tests.

Blood Sedimentation Rate in Diabetes Mellitus—

Kramer performed 510 tests on 366 office and outpatient patients. The technic employed in the study was the one advocated by Cutler. Abnormal readings were obtained in 346 (67.8 per cent) of the 510 sedimentation tests. The explanation for this high percentage must be either the diabetes or the

presence of infections, or both. A study of the duration of the diabetes showed that the maximal difference of the percentages in the various diabetic groups was only 5.3 per cent. These figures evidently do not permit one to attach much significance to the effect of the duration of the diabetes on the sedimentation rate. Also the possible influence of the blood sugar was studied. There was a striking similarity of the percentages in the hyperglycemic group and those whose blood sugar was 180 mg or below. In the former there were 194 cases (67.1 per cent) which showed abnormal lines, and in the latter (nonhyperglycemic group) there were 152 records (68.8 per cent) with abnormal lines. The blood sugar by itself had no influence on the sedimentation rate. Since the duration of the diabetes and the blood sugar cannot explain the high incidence of the abnormal sedimentation rates, the inference is that the most likely explanation is infection. Analysis of the patients showed a high incidence of the minor infections, particularly in the teeth, tonsils and upper respiratory tract. However, the urinary tract and gallbladder must also be kept in mind.

Improved Congo Red Test for Amyloidosis—Friedman and Auerbach state that the disadvantages of the congo red test for amyloidosis can be overcome by the use of ethyl alcohol which precipitates the proteins and dissolves the congo red giving a clear solution that can be read with the colorimeter. The test is carried out on the patient in a postabsorptive state. Ten cc. of a 1 per cent congo red solution is injected into a vein and four minutes later about 10 cc. of blood is withdrawn from another vein. The second sample of blood is taken one hour after injection. It is advisable for the tubes to stand about two hours, permitting the clots to retract. The tubes are next centrifugated at a moderate speed (3,000 revolutions per minute) for ten minutes and the serum is decanted carefully. Two cc. of serum is pipetted into 15 cc. graduated conical test tubes and made up to 10 cc. with 95 per cent ethyl alcohol. The tubes are corked, shaken for thirty seconds and centrifugated at a high speed for ten minutes. The clear supernatant fluids are poured into colorimeter cups and readings are made on the colorimeter. The readings are best when the four minute specimen is set at 20 mm. The calculation is 100 minus the factor of a four-minute reading divided by a one hour reading multiplied by 100 equals per cent absorption. The solution remains unchanged indefinitely when corked. Lipoidal serum gives a very clear supernatant alcoholic solution.

Inguinal Lymphogranuloma—During the last three years Marbury has seen twelve cases of lymphogranulomatosis showing stricture of the rectum. In all but one case in which colostomy was performed, the treatment has been digital dilation of the strictured area with the patient under general anesthesia. He feels sure that many more cases of lymphogranuloma have been seen in the outpatient department but have not been recognized or treated. The condition seems to be limited to individuals in the lower walks of life although he believes that several patients from the middle strata would have given a positive reaction to the specific antigen. Eleven of the twelve patients having rectal stricture were Negro women the other a white male. Their ages ranged from 18 to 40 years, spanning their active sex life. All the patients complained of piles. On further inquiry they admitted that they had had a change of intestinal habits beginning from one month to seventeen years previously. The usual history was that there had been a progressively increasing constipation, which required more and more cathartics and resulted in very painful stools. None of the patients admitted having any remembrance of a primary sore, though most of the women said that they had had some vaginal discharge at times. The Wassermann test was negative in seven cases, positive in three and was not made in two. The Frei test was positive in the three cases in which it was performed. The constricted area gave much more readily to dilation than it does in cases of carcinoma or of stricture due to scar tissue. When the area was sufficiently dilated, a large well lubricated rectal whistle, 5 inches long and 1½ inches wide was inserted and left in for two days. During this time the patient was given a generous allowance of morphine. When the whistle was removed, retention enemas of warm water and hamamelis were given twice daily. The patients have usually remained in the hospital less than a week and on discharge they have been instructed to keep up the enemas and to return to the dispensary for treatments. Dilation with bougies is carried out once or twice a month or as long as the patient continues to come to the dispensary.

Diathermy in Lobar Pneumonia—Wetherbee and his co workers employed the standard treatment for lobar pneumonia, including serum and/or oxygen when indicated, in thirty-six cases. In addition, one half of these patients, alternately chosen were given physical therapy in the form of diathermy. The mortality for the entire series was 22.2 per cent, for the diathermy group 11.1 per cent, and for the control group 33½ per cent. The cases are presented in some detail and the effects of diathermy noted. Lobar pneumonia is a self-limited disease. If during its course rest and relaxation can be obtained, if the patient can be made comfortable, the pain eased, the dyspnea relieved and the apprehension lessened or if, in other words, the patient can be carried along until such time as the illness has run its course, the most valuable thing will have been done that can be done in any self-limited disease. The authors feel that if the mortality of lobar pneumonia is ever lowered it will be as a result of treatment directed along these lines rather than as a result of any more specific treatment. They do not imply that serum, for instance has no value. The fact remains, however, that in any large series of cases the mortality is about what it was before serum was used. There is beyond question a growing feeling that specific therapy is not as valuable as it appeared to be at first. Because the mortality in the diathermy group was one-third that of the control group and because of the definite subjective improvement in the patients treated by this method, they feel justified in continuing with this form of treatment until a sufficiently large series of cases with controls, has been accumulated and more definite conclusions can be drawn.

Prostatic Hypertrophy—Reitzel used a 20 per cent solution of silver nitrate with from 1 to 4 per cent nitric acid in cases of prostatic hypertrophy the acid addition depending on the degree of alkalinity of the urine. The urethra was anesthetized with butyn or metycaine (2 per cent solution) and the bladder was drained through a catheter lubricated with a water soluble jelly. A urethroscope was inserted and the prostatic urethra

dried with a cotton wrapped probe. A tubular metal instrument, slightly curved and fitted with an obturator, was passed into the prostatic urethra and the obturator was withdrawn. From 20 to 25 drops of the acid silver solution was run into the tube and the obturator was reinserted and pushed home. From three to five such treatments were given at intervals of from three to five days. The author has employed the treatment in 103 cases to date. Most of the cases have been followed up and reports are gratifying.

Vitamin A Deficiency as Shown by Visual Photometer

—Park shows the therapeutic value of vitamin A in a number of pathologic states and in seemingly healthy individuals and calls attention to the use of the photometer, according to the technic of Jeans and Zentmire, as a simple method to be used by the general practitioner for the detection of vitamin A deficiency and for measuring response to vitamin A therapy. The author has tested more than 275 individuals, including normal cases, gastro-intestinal disorders, sinus and miscellaneous infections, nervous and mental conditions, kidney disorders, pernicious anemia, leukemia, diabetes and marked night blindness. Carotene or provitamin A rapidly restores the vitamin A content in cases in which its activity is not hindered by disease or complications that serve to prevent its absorption and conversion. No bad effects have been noted from the use of carotene in oil in large doses. From the tests made covering people in every walk of life, it appears that a large proportion of our population is low in vitamin A. There is no definite proof that vitamin A is anti-infectious, but all results point to its action as a barrier against infection by stimulating healthy epithelial tissue. The author states that examinations of specimens of liver from 300 necropsies (Moore) for vitamin A showed about the same results as found by the photometer in his series, the different pathologic states showing the same proportionate deficiency as found by the photometer.

Hyperthyroidism and Heart Disease—Ryan states that the presence of hyperthyroidism may easily be overlooked as the basic cause of cardiac symptoms. When the patient applies for treatment, the cardiac symptoms may be of such severity that the immediate therapy is directed to the heart. This mistake may be avoided by insisting on a basal metabolic rate determination in all cases of cardiac disease. The hypertension case and the colloid goiter in the young should not be erroneously diagnosed as hyperthyroidism until repeated estimations of the basal metabolic rate have given a true basic reading. Occasionally in the borderline case the Goetsch test will give valuable diagnostic information. The presence of paroxysmal tachycardia or fibrillation should suggest immediately that the thyroid is hyperfunctioning. A case of a large nodular goiter involving the whole left lobe of the thyroid and associated

general anasarca involving both lower extremities, the abdomen and both pleural cavities is discussed. The radial pulse was very rapid and irregular. Marked dyspnea and cyanosis were present. Medical therapy was directed to the heart with little success, and operation was deferred because of the poor condition of the patient. It was hoped that, as improvement occurred in the heart, a thyroidectomy might be performed. The improvement in the heart did not occur; the patient developed bronchopneumonia and later an uncontrollable neurosis. Two months after admission it was decided that a thyroidectomy should be attempted, and the left lobe of the thyroid was completely removed under local anesthesia. The right lobe was examined at the time of operation and found normal. Examination one year after operation showed that the patient had gained 70 pounds (31.8 Kg.). Her pulse rate was 90, and the rhythm was normal. The tone was good, and no murmurs could be heard. The heart was completely compensated.

Hypoglycemia as Cause of Mental Symptoms—Because of definite evidence in the literature that many of the symptoms of hyperinsulinism are mental, Greenwood has looked for these cases in psychopathic wards of the Philadelphia General Hospital. It is significant that there is a somewhat higher percentage of low blood sugar determinations found in psychopathic patients than in patients in the general medical and surgical wards. The diagnostic features are (1) a psychosis, which may take almost any form, often violent in character and belonging to the organic group in that the sensorium is always affected; (2) psychotic manifestations, which alternate with periods of normal behavior, a more or less transient psychosis depending on the severity of hypoglycemia; (3) a low blood sugar estimation during the psychotic period; (4) relief from symptoms when dextrose is given; (5) a high dextrose tolerance, as evidenced by a dextrose tolerance curve, which is below normal either during the period of fall or at any point in its course; and (6) a tendency for the psychotic episodes to occur in the early morning, late at night or occasionally just before mealtime. Starvation or irregularity in meals seemed to be a precipitating factor in three of the six cases reported. The omission of a meal might cause a low blood sugar level to descend further to a dangerous point and so initiate the mental symptoms. There is little doubt that hypoglycemia may cause a definite psychosis necessitating institutional care, and it is important for the general practitioner to be able to recognize these cases. The symptoms are so quickly relieved by the oral or intravenous administration of dextrose that confinement in a mental hospital could be avoided, except in a few of the more severe cases.

Treatment of Anemia Associated with Hookworm—Rodriguez Molina's study of five cases suggests that iron administered in large daily doses (6 Gm.) is the treatment of choice in the anemia associated with hookworm disease as compared to liver extract with iron by mouth, to a widely known commercial preparation used in the treatment of secondary anemia, and to a well balanced full hospital diet. The administration of each of the therapeutic agents used during a period of thirty days without removal of the worms resulted in a rise of the red cell count and hemoglobin percentage to a practically constant subnormal level. This level was reached more quickly by patients receiving iron alone. After this rise there was no further significant increase previous to removal

of the worms Administration of an anthelmintic was followed in all cases by a rapid (from five to seven days) increase in the red cell count to normal values In the two patients who received iron alone a rapid increase in hemoglobin parallel to the increased red cell count was observed. It is inferred that intensive iron therapy and a well balanced and nutritious diet aided by an effective anthelmintic seem to provide the optimal conditions of a rapid recovery from the chronic anemia encountered in hookworm disease.

Radiotherapy of Sarcoma of Soft Parts—In reviewing the statistical results in relation to the therapeutic method used in sarcoma of the soft parts, Leucuta finds that neither surgery nor radiation therapy has hard and fast rules As concerns the former, though the general principle may be that every operable sarcoma should be removed at once, there are instances in which primary radiation therapy may appear of greater benefit. Especially is this true of some highly cellular sarcomas of the fibroblastic group, such as round cell sarcoma of the tonsil or any other location, reticulum cell sarcoma, large spindle cell sarcoma and the like, of the myxosarcomas, liposarcomas and xanthosarcomas and of the Kaposi sarcoma of the skin Moreover, when biopsy is taken in all these instances it appears considerably safer to attempt to remove a metastatic node rather than to try to cut into the tumor proper As concerns radiation therapy, the degree of radiosensitivity forms the basis of procedure. Yet radiosensitivity in the clinical sense may mean "spectacular regression in one case and slow progressive tumor shrinkage in another The criteria dominating such response must be closely scrutinized and classified. It will be found that in the majority of cases they may be harmonized to greater advantage with surgical indications and that, therefore, an association of surgical and radiotherapeutic methods in the treatment of sarcoma of the soft parts must constitute an essential and most desirable requirement. In the same sense statistics dealing with a combination of the two methods rather than their opposition will prove of the greater clinical value.

Roentgen Treatment of Certain Types of Arthritis—Garland believes that, besides being contraindicated in arthritis in patients with cardiac disturbances, marked arteriosclerosis and nephritis, pyrotherapy appears to be more uncertain in its results than roentgen therapy He treated nine cases of acute infectious arthritis in which a total of thirteen individual joints were involved Four patients became free from symptoms two were considerably improved and three were not improved Absence of the immediate and often spectacular relief that occurs in cases of gonorrheal arthritis was conspicuous Three cases of chronic infectious arthritis were treated, in which ten individual joints were involved. Two cases became free from

symptoms and one was not improved at all Seven cases of chronic degenerative arthritis of the spine (spondylitis deformans) were treated Only one became symptom free, four were improved and one was not improved. Thirty cases of acute infectious (gonorrheal) arthritis were treated with small doses of x-rays delivered to the involved joints twice weekly for two or three weeks Twenty-eight cases (93 per cent) were much improved and two (7 per cent) were unimproved Approximately half of the improved cases appeared to be completely cured within a few weeks of the end of treatment, the remaining cases improved gradually, but, while there was freedom from pain, some slight stiffness or disability remained in the involved joints Five patients, in whom the joints were left untreated as controls, showed no improvement in the joints that were not treated

Thyroidectomy for Hyperthyroidism with Manic Depressive Psychosis—To explain the development of psychosis in connection with hyperthyroidism, Long calls attention to the supposed role of the thyroid in controlling cerebral circulation. In hyperthyroidism there are tachycardia, increased arterial tension and increased metabolism. It is reasonable that in connection with these phenomena there might be an increase of the blood supply to the brain to the extent that mental disturbances would be produced. The etiologic role of the toxic products of hyperthyroidism should be considered also. If this reasoning is sound, it follows that thyroidectomy ought to be followed by a modification of the abnormal cerebral circulation and by a reduction of toxic material going to the

brain The author has seen a few patients who had so called thyroid psychosis (toxic psychosis), which appeared at the height of hyperthyroidism, either shortly before or after operation, and was quickly alleviated by control of the hyperthyroidism, by administration of iodine or operation, or by both. The three cases that they report have not been of this type but have instead exhibited long standing frank manic depressive psychosis before operation, which cleared up slowly following thyroidectomy. The period of active postoperative psychiatric treatment has averaged two years, but at the end of that time these patients have been regarded as mentally cured. This belief exists with the full knowledge that manic depressive psychosis untreated, shows remissions. In each of these the mental and physical results have been so satisfactory that the author feels that thyroidectomy is worth while and is a means of securing permanent relief from the physical, and apparently permanent relief from the mental, disturbances. These patients, who have been under the careful observation of competent mental experts, are said to be mentally cured and are now leading healthy useful lives.

Renal Changes in Hypertension—MacMahon discusses the renal changes in "primary" hypertension. A study of a large number of cases belonging to the group of "primary" hypertension shows that one is not dealing with a single but with several clinical syndromes. Four groups are considered: (1) temporary hypertensions of young and middle-aged persons observed during certain of the toxemias of pregnancy, (2) permanent hypertension uncomplicated by clinical signs and symptoms as seen in young individuals, (3) permanent hypertension of middle-aged and elderly persons associated with a variable degree of generalized arteriosclerosis and (4) permanent, though variable, hypertension in young and middle-aged individuals associated with destructive and inflammatory lesions throughout the body—known as malignant nephrosclerosis. Patients having temporary hypertension during toxemia of pregnancy may develop in later years the classic signs and symptoms of malignant nephrosclerosis. The great majority of patients of the second group ultimately fall into one or the other of the two remaining groups—benign or malignant nephrosclerosis. This might suggest a link in common between these groups and indicate that they are not different diseases but only different phases of the same disease. In favor of such a hypothesis, perhaps, is the indisputable fact that borderline and transitional forms do occur which do not fall clearly into any one of these four groups. These impressions, however, in no way contradict the observation that, at least on the basis of morphologic pathology, each may exist as a distinct and separate disease but rather suggest that from the standpoint of etiology certain factors may be common to all.

Experimental Anemia in Monkeys—The experiments of Wills and Stewart show that the hematopoietic system of the rhesus monkey behaves in a manner remarkably similar to that of man. Only the bone marrow hypertrophy in macrocytic anemia in monkeys differs from that in man. The megaloblastic reaction was similar to that seen in pernicious and other human macrocytic anemias, but the large, pale primitive cells, which were present in such large numbers in the marrow from some of the animals, are not commonly seen in preparations from human material. These cells were found in greatest number in the bone marrow from a monkey that died during a blood crisis, during which numerous nucleated red cells appeared in the blood stream and they would appear to be stem cells though their relation to the red and white cell series could not be determined from preparations (since identified by Turnbull as leukoblastic cells of the neutrophil series). No consideration of macrocytic anemia in animals should fail to include the possibility of a Bartonella infection. Thus a macrocytic anemia has been produced in intact rats on deficient diets. This anemia, however, was accompanied by the appearance of Bartonella bodies in the circulating blood, and, while many animals died in the acute stage of the illness, those that survived made a spontaneous recovery, the anemia disappearing without any specific treatment (Wills and Mehta, 1930). Recently also Miller and Rhoads (1935), who have induced a macrocytic anemia in dogs by faulty feeding, have reported the finding of Bartonella canis in their experimental cases after splenectomy. The interpretation of this is obscure, as the Bartonella bodies were never found in nonsplenectomized animals fed on the same faulty diet, even after they had received injections of blood from the infected animals. Moreover, the infected animals could be cured of their anemia, with the disappearance of the Bartonella bodies, by adding lean meat to the diet. The question of whether a latent Bartonella infection is present in the monkeys has not been determined.

Radiologic Estimation of Fetal Maturity—Roberts describes a method for estimating the maturity of the fetus from certain cephalic diameters. The patient is placed in the prone position, the weight resting on the elbows, with a cast beneath her. If not already in contact, the hypogastrum is

brought into contact with the case. The X-ray tube is centered above the fetal head at a distance of 4 feet and a roentgenogram is taken (50 milliamperes at 60 kilovolts, three seconds). The suboccipitobregmatic diameter is most frequently seen on the film and can be measured by a ruler (preferably of the transparent type) marked off in tenths of an inch. (Failing this, the diameter intermediate between the suboccipitobregmatic and biparietal will be seen and measured or, more rarely still, the biparietal diameter itself.) The diameter in inches so measured multiplied by 10 will give in the majority of cases a fairly accurate estimate of the fetal maturity. For instance, a suboccipitobregmatic diameter of $3\frac{7}{10}$ inches will in an average case indicate a fetal maturity of thirty-seven weeks. If the patient is fat, or if it is impossible to bring the hypogastrium into contact with the case, or if a lateral view shows the position of the head to be occipitoposterior, a week or, in extreme cases, two weeks should be deducted from the maturity computed. The method is recommended only for single vertex presentations. If difficulty is experienced in roentgenography at 4 feet without a Bucky diaphragm, a formula and table are given for estimating the maturity from the prone Potter-Bucky roentgenograph at 30 inches. If the Potter-Bucky diaphragm is used, the film should be $1\frac{1}{2}$ inches from the surface of the Bucky table. The author presents this method as a preliminary note. There has as yet been insufficient time or opportunity to test out the method in a large number of cases. From the small number of cases examined, however, he feels that it will be of help.

Rectal Hemorrhage and Meckel's Diverticulum—Chasterman reports four cases of rectal hemorrhage due to peptic ulcer of Meckel's diverticulum. The ages of the patients were 6, 11, 16 and 22 years. From the available literature the etiology of all forms of bleeding due to disease of this diverticulum is given together with the differential diagnosis. The following in their order of frequency, may be associated with the hemorrhage from the rectum: anemia, pain, vomiting and intestinal irregularity. The diagnosis is made by a process of exclusion, though rectal hemorrhage in a juvenile between the ages of 5 and 15 years especially if a boy, is very suggestive. The hemorrhage is usually sudden and severe, though in cases of growth it may be slight and continuous. Pain occurs in about half the cases is of colic type and never severe and prolonged unless associated with intestinal obstruction and is

situated in the umbilical region. Laparotomy for the removal of an ulcer containing diverticulum is urged in children between the ages of 5 and 15 years showing rectal hemorrhage the cause of which is not revealed by sigmoidoscopy and blood examination.

Thrombosis Following Strain—Robinson has seen two cases of primary thrombosis, the result of excessive muscular effort affecting the thoraco-epigastric vein of the right side. The patients were healthy and in the prime of life, there was little subcutaneous fat, so that the vein was both visible and palpable. In one the condition developed after digging in the garden and in the other after shifting some heavy furniture. The symptoms were pain felt in the side of the chest wall and the discovery of a tender cord. On examination a stringlike band under the skin, running up from the costal margin just behind the breast under the anterior axillary fold and disappearing in the axilla, was palpable and tender. The physical signs cleared up completely in six weeks. The condition is of clinical interest particularly in the female sex, because its close relationship to the breast may give rise to confusion in diagnosis. As a cause of thrombosis one can postulate congestion and injury of the venous intima during contraction of the underlying muscles, possibly with injury of the valves in the lumen of the vein. It is possible that axillary thrombosis may originate in this vein, the primary thrombosis being overlooked in the major condition affecting the axillary vein, especially as it is unlikely that the patient will draw attention to the original condition.

Lymphatic Spread in Cancer of Rectum—Gabriel and his co-workers discuss a means for the examination of operative specimens of cancer of the rectum in order to determine the extent of lymphatic spread. As a rule the regional lymph nodes are the first to be affected by metastases in cancer of the rectum. Lymphatic spread then proceeds from below upward along the chain of glands accompanying the superior hemorrhoidal artery. Irregular or interrupted spread is uncommon. Lateral or downward lymphatic spread is found only in a late stage of the disease when the hemorrhoidal lymphatics are blocked by metastases. The examination of the operative specimens permits a distinction to be made between cases in which glandular spread has already reached the glands at the point of ligation of the inferior mesenteric pedicle and those in which the upward spread has not extended to this point. The prognosis in the latter is thought to be much better than in the former. In the 100 glands dissected the authors found lymphatic metastases in sixty-two cases. This is a slightly higher proportion than is usually reported in any series of operation specimens of cancer of the rectum. The dissection of seventy specimens removed by perineo-abdominal excision showed that in only a small proportion (eleven) the disease had actually spread by lymphatic channels to the limit of surgical removal, that is, the inferior mesenteric pedicle.

Relapses in Pulmonary Tuberculosis—Wingfield states that there are three forms of relapse. They differ completely in their pathology, symptomatology, recognition, prevention and treatment. 1. Relapse due to the deposition of an entirely fresh lesion in a heretofore undiseased portion of the lung—new lesion relapse. 2. Relapse due to spread by contiguity of a heretofore quiescent or arrested lesion—spread relapse. 3. Relapse due to

changes taking place in an apparently arrested lesion, unaccompanied by actual spread of the diseased area—late relapse. The pathology, etiology, clinical evidence, physical signs, appearances, clinical course, recognition and treatment of each type are discussed.

Significance of Shape of Fetal Head—Rydberg gives a historical survey and a critical examination of theories advanced in explanation of the mechanism of labor, heretofore no generally accepted explanation has been found. His investigation of the shape of the fetal head shows that it has a decided and characteristic asymmetry, in that the bulk of its mass is situated above the mento-occipital diameter. An investigation as to how this asymmetry may be conceived as determining the movements of the head during labor shows that the usual mechanism can be traced to it, if it is assumed that the deformability of the birth canal corresponds on the whole with that of a curved tube of a homogeneous elastic material. Cases in which the normal internal rotation is absent are also explained, if the atypical deformation of the fetal head appearing in these cases is obvious. The author believes that the shape of the fetal head is the factor which chiefly determines its movements during labor, and that an incomplete forward flexibility of the fetus at most may have some importance in cases of prolonged occipitoposterior position. He states that the hypothesis is in itself reasonable and is supported by what can be observed dur-

ing obstetric work. The movements of the fetal head during labor are fully explained by its shape alone. The conception that the shape of the head is the essential and decisive factor is strongly supported by all obstetric experience, which testifies unmistakably as to the dominating importance of the head for the whole course of labor under both normal and pathologic conditions, and to the high degree of plasticity and passivity of the fetal body and neck.

Malaria During Pregnancy—Wickramasuriya asserts that quinine is still indispensable in the treatment of malaria in gravid as well as nongravid women. Pregnancy is not a contraindication to its use. Clinical experience does not suggest that quinine administered in therapeutic doses possesses oxytocic powers. Far from being an oxytocic, quinine administered in effective therapeutic doses, by rapidly controlling the malarial infection and the high temperature, prevents premature interruptions of pregnancy and intra-uterine fetal death. Atabrine is regarded by many as an alternative to quinine in the treatment of malaria during pregnancy. While it should be regarded as a useful addition to the therapeutic armamentarium, it must be said to occupy but a subordinate place to that of quinine in the treatment of the disease during pregnancy, as it does not control the malarial infection and the high temperature so rapidly. Relapses do occur after its use as with quinine, and whether it is as efficacious and as safe for general use as quinine is yet to be seen. Atabrine appears to be contraindicated in patients with toxemia of pregnancy, preexisting nephritis and advanced hookworm disease.

Effects of Sodium Citrate on Alkali Reserve—As the results of the intravenous injections depend on the amount of citrate injected and as intramuscular injections are given to make the blood more coagulable, de Souza and Hocking believe that it is important to know whether the effects of the intramuscular injections, both on the coagulability of the blood and on the alkali reserve, show a similar dependence on the quantity of citrate. Their results show that an intramuscular injection of 0.125 Gm. per kilogram of body weight may be safely and effectively given to increase the coagulability of the blood, but that an injection ten times as large eventually diminishes coagulability and may in certain circumstances produce tetany. Repeated small intramuscular injections of sodium citrate have a cumulative effect in increasing the alkali reserve and the coagulability of the blood. Anesthetized cats were used for the experiments.

Bacteremia and Oral Sepsis—In searching for the source of streptococci concerned in the production of subacute bacterial endocarditis, Okell and Elliott state that attention must inevitably be turned to the oral cavity. The majority of endocarditis streptococci are of the salivary or *Streptococcus viridans* type. These abound in the mouth and its neighborhood but are found elsewhere only in small numbers and under exceptional conditions, above all it is in conditions of oral sepsis such as pyorrhea of the gums, that this type of streptococcus is found in the greatest numbers. The blood was examined for bacteria in 138 patients undergoing extraction of teeth. Eighty-four of these showed a transient streptococcal bacteremia after extraction, and in cases considered to be of a severe type of oral sepsis (group A) the positive streptococcus cultures reached as high a figure as 75 per cent. In all cases from which streptococci were recovered, the organisms were of the nonhemolytic type. In the majority of cases in which the result was positive, streptococci were recovered from the cultures grown under aerobic and anaerobic conditions of cultivation, and in a few instances the organisms were found in the aerobic or anaerobic cultures. None of the streptococci recovered were obligatory anaerobes. In general, it was found that the occurrence and degree of a bacteremia depended on the severity of the disease of the gums and the amount of damage done at the operation. The bacteremia following extraction is of short duration. The transient bacteremia following operative trauma is analogous with that described by Barrington and Wright in catheter fever in which *Bacillus coli* was the usual organism isolated from the blood. In persons with severely septic mouths, nonhemolytic streptococci (mostly of the *viridans* type) may enter the blood stream in the absence of any obvious trauma. The authors have been unable to ascertain whether the condition of "leak" into the blood stream in the positive cases is continuous, intermittent or merely a fortuitous single occurrence. Nor have they yet determined whether minor traumas, such as brushing the gums or chewing have any effect on the occurrence of the bacteremia. The efficient mechanism which exists for clearing the blood stream of organisms of low virulence, no doubt allows a leak of organisms into the circulation to be detectable in blood from an arm vein only when the leak exceeds a certain magnitude or the organisms are abnormally resistant to phagocytic clearing. The leak, which is of little consequence in the normal person, might determine the infection of diseased or malformed valves. The direct observation of such an invasion of blood provides a tentative explanation of how streptococci reach the cardiac valves in cases of subacute bacterial endocarditis.

Sympathectomy in Trophic Disorders of Lower Limbs

—Danielopolu and his associates practiced interlumbosacral sympathectomy in cases of arteritis of the lower extremities. It consists in sectioning of the sympathetic cord above the promontory. They feel that this procedure is preferable to lumbar sympathectomy for several reasons. It satisfies the necessary physiologic and anatomic principles and is technically relatively easy to perform without producing the occasional paralytic ileus of some of the other methods.

Stasis in Pathogenesis of Biliary Lithiasis—Pavel

advances several arguments which militate against the generally accepted concept that stasis is a necessary prerequisite to the formation of gallstones. There have been numerous cases of prolonged biliary stasis, confirmed by operation or necropsy, without any development of stones. Furthermore, recent studies of icterus from functional stasis due to spasm of the sphincter of Oddi have shown that it does not favor the formation of calculi. Cholecystography has furnished additional evidence of this view. There are numerous instances in which atony of the gallbladder has been found without any stones. On the other hand, vesicles have been seen showing normal contractile powers, but nevertheless containing stones. The author feels that all these observations tend to prove that the classic idea of stasis should no longer be accepted uncritically.

Hyperpolypeptidemia in Tetanus—Warembourg and

Driessens describe three cases of tetanus. One patient, after being accepted as having recovered from his infection, died later of uremic coma, and the other two patients, before dying of tetanus, showed signs of grave blood uremia with marked hyperpolypeptidemia. The cause was investigated from a clinical, chemical and morphologic standpoint, but the authors were unable to relate this to any deficiency in blood chlorides. Systematic histologic study of the organs was practiced with the aim of determining any preexisting chronic disorder of the liver or kidneys or any acute lesion of these organs that might play a part in the uremia. No old lesions were found at first but acute and subacute changes of great importance were noted. The authors therefore concluded that the important etiologic factor was probably the continuous administration of strong doses of serum loaded with foreign proteins. The resulting increase in the blood urea nonprotein nitrogen and polypeptides coincides with an intense congestive hepatitis and nephritis. The final responsibility of the therapeutic maneuvers in the determination of this intoxication remains to be clarified. Certain practical conclusions may be drawn, nevertheless. Naturally, antitoxins must still be administered but the course of the blood urea should be watched, diuresis should be favored by the administration of isotonic or hypertonic dextrose solution, the patient may be given liver extracts, and the antitoxin that is administered should be as free as possible from heterogenous proteins.

Casuistic Contribution to Therapy of Gastric Ulcers F. Leins—p. 1054

Interreno-Insular Syndrome—Askanazy and Sciclounoff describe the clinical observations and the necropsy on a girl, aged 20. The clinical symptoms were edemas, severe atrophy of some of the organs, bradycardia, hypotension, hypothermia, hypoglycemia, amenorrhea and dryness and pigmentation of the skin with lanugo formation. Since implantation of hypophyseal tissue had effected a certain improvement, a hypophyseal cachexia seemed possible. The necropsy, however, disclosed that this diagnosis was erroneous. There was hyperplasia of the adrenals, the pancreas was of normal size, but practically all other internal organs showed severe atrophy. The authors describe the histologic aspects of the organs, pointing out that the most noteworthy changes were detected in the pancreas, in that the number of its islands was greatly increased. This polynesia was found in all parts of the pancreas, the islands being about two and one-half times as numerous as is ordinarily the case. The structure of the islands was normal. The authors regret that they were unable to subject the enlarged adrenals to microscopic examination. In their interpretation of the pathologic observations they say that the adrenals and the pancreas are antagonistic, which would make a hypofunction of the adrenals seem logical in a case of polynesia. However, the pancreas and parathyroids are considered blood sugar reducing organs, and the thyroid hypophysis and adrenals as blood sugar increasing organs. Since in this case the sugar reducing action was driven to the extreme, the organs that produce the blood sugar probably were overtaxed. The authors assume that this explains the hypertrophy of the adrenals. Moreover, if the action of the hypophysis is compensatory for the sugar reducing polynesia, it is understandable why the implantation of hypophyseal tissue effected some improvement. They discuss the case also from the point of view of a primary adrenal hyperplasia, pointing out that among the various pathologic manifestations of adrenal hyperplasia there are two types, those which seem to be the result of the increased production of adrenal hormones and those in which, in spite of the hyperplasia, a disordered or deficient hormone function seems likely. The clinical aspects of the described case contradict the first type, for it is usually accompanied by obesity, hypertension, hyperglycemia and so on. In the second type there develop signs of an intoxication which, particularly in the case of newborn infants, rapidly brings on a fatal outcome. The clinical picture of the latter type is usually that of a severe atrophy which was the case also in the girl whose history is described, but in some respects this case deviated somewhat from the symptomatology of other cases. The authors concede that the question of a causal relation between primary polynesia and fatal cachexia cannot be definitely answered on the basis of this case. Nevertheless, there is an interrenopolynetic syndrome.

*Importance of Silk Suture in Genesis of Postoperative Peptic Ulcer F. Paolucci—p. 852

Rare Tumors of Thyroid A. Billi—p. 863

Silk Sutures and Postoperative Peptic Ulcer—Paolucci performed in six dogs the operation of transmesocolic posterior gastroenterostomy combined with pyloric exclusion according to Eiselsberg using silk threads as suture material. In a second series of six dogs he severed the duodenum directly below the pylorus and closed the two stumps, he performed a transmesocolic posterior gastrojejunostomy according to von Hacker. He severed the duodenum below the entrance of the pancreatic duct and closed its distal end by a purse string suture, and he made a terminolateral anastomosis between the proximal end of the duodenum and the last loop of the ileus from 10 to 20 cm. from the cecum. Five dogs of the first series and four of the second survived the operation. Fifteen days after the

operation, on histologic examination, one of the five dogs showed a small tissue loss without the characteristics of a true ulcer and the presence of a long silk thread in the shape of a loop. The tissues at the anastomotic suture points were slightly edematous and hyperemic. In the right anterior portion of the anastomosis in another dog, the author found a tag of omentum, markedly hyperemic and adhering to the stomach and to the jejunum. The tag occluded hermetically a small ulcer involving the anterior wall of the jejunum. No silk threads were observed on the margin of the ulceration. Numerous loops of silk thread were present at the lumen of the anastomosis without there being a trace of ulceration. Below the tag of hyperemic omentum there was a second round ulcer with clear cut margins about 3 cm. from the left angle of the anastomosis. Ulcers were found in the jejunum of each dog of the second series. In all the loss of substance was of variable size and the ulcers were always round and had clear cut margins. They were always observed in the jejunum on the afferent or efferent loop at various distances from the anastomosis. In the two ulcers produced in the first series of dogs no suture thread was found, whereas at the sites of the sutures no ulcers were present. The ulcer produced on the afferent loop was at such a distance from the anastomotic stoma that it excludes any possible influence of the sutures. The ulcers present in the second group, constantly found in the jejunum on the afferent and efferent loop, could not be attributed to the presence of sutures, because the losses of substance were produced at a distance not only from the anastomosis but also from the loops of suture. The author concludes that there is no relation between postoperative peptic ulcer and the silk thread suture.

*Action of Irradiations from Lecithin on Development of Bacteria. G. Acanfora—p. 1475

Effect of Irradiations from Lecithin on Bacteria—Acanfora proved that the radiations of lecithin that has been submitted to radiations of light inhibit the cultural development of certain fungi. His work was reported in the *Annali di medicina navale e coloniale* 41 193 (March-April) 1935. The author repeated the experiments by subjecting cultures of bacteria especially those of the *Bacterium melitense* group, to the same irradiations in order to ascertain whether or not they have the same action on the cultural development of bacteria as they have on that of fungi. He found that these irradiations have no action on the cultural development of bacteria, except in the case of bacteria of the paratyphoid and meta dysentery groups. This different behavior of lecithin irradiations is due to the fact that fungi are less differentiated organisms than bacteria. While the irradiations have an inhibitive action on the former, the latter can stand it and even derive some benefit from it in certain cases.

*Painful Nodule of the Ear Case E. L. Othaz—p. 1105

Treatment of Trachoma by Diathermocoagulation—Von Grolman states that diathermocoagulation is the surgical treatment of choice in trachoma. The scars it leaves in the palpebral conjunctiva are small and nonretractile. The operation is not complicated by entropion, symblepharon, hemorrhages and shock. It has a thrombotic and hemostatic action on the vessels of the operative field and causes sterilization of the tissues and complete destruction of the granulations. Its

technic is simple and rapid. Owing to the fact that there are several methods for graduation of the intensity of the currents, it is possible to determine the proper dose to be given and to repeat the operation whenever it is necessary.

Painful Nodule of the Ear—Othaz makes a general study of painful nodules of the ear, in the etiology of which heredity, climate and nationality of the patient do not play a part, but trauma and the action of either heat or cold may. While infection is not the cause of the disease, it may complicate it. As a rule, it is a solitary unilateral growth seated at the helix. The predominant symptom is spontaneous or provoked intense pain of the neuralgic type, related to the congestive condition of the ear. Some relief is obtained by removing the little scar covering the nodule. The evolution is chronic. The differential diagnosis should be made with Darwin's tubercle (congenital malformation of the helix), verruca vulgaris, gouty tophus, cyst and epithelioma. The prognosis is good.

Changes in Fat Metabolism Before Onset of Labor Pains During Normal Pregnancy Contribution to Problem of Onset of Birth G Effkemann—p 718

Genesis of Brenner Tumors—Fauvet describes and discusses the histories of four women with Brenner tumors and then gives his attention to the genesis of these tumors. He evaluates the theories advanced by others in the light of his own observations. He emphasizes that the comparison between the endometrioses and the Brenner tumors should not go too far insisting that the Brenner tumors are always of ovarian origin whereas this cannot be said about the endometrioses. But, although always of ovarian origin, the Brenner tumors apparently may derive from various elements in the ovaries either from Walthardt's cell foci, as Robert Meyer assumes, or from the ovarian rete, as is indicated by Schiller's and the author's own observations. In discussing the hormone aspects of the Brenner tumors, he emphasizes that in his cases he observed nothing which would justify the assumption that their development is regulated by ovarian hormones. On the contrary, he gained the impression that the development of the Brenner tumors is promoted by the subsidence of the ovarian function. In this connection he calls attention to von Behring's statement with regard to hemorrhagic metropathy, chronic cystic mastopathy and the endometriosis, which that author regards as "paramenstruations" and not as the result of hyperfunction, but rather of a dysfunction of the gonads assuming that other substances might become active as the result of an insufficiency of the ovaries. The author says that the analysis of his own cases indicates that other than ovarian hormones play a part in cases of Brenner tumors. He gave his attention to the adrenal cortex but reaches no definite conclusion since the knowledge about the functions of this organ is as yet incomplete.

Changes in Fat Metabolism and Onset of Birth—Effkemann discusses the incretory changes that take place in the pregnant organism before the onset of labor and reports his own studies on the changes in the fat metabolism. He found that from three to six days before delivery the fatty acid content of the blood increases slightly over the values that are found during the second half of pregnancy. He observed values of from 700 to 850 mg per hundred cubic centimeters. He further observed that the acetone bodies increase likewise before the onset of the labor pains. The acetoneuria of pregnant women which on the average amounts to 240 mg commences to increase with the sixth day before delivery and reaches values of 640 mg in the daily urine. The anterior hypophyseal hormone of the fat metabolism is slightly increased in the blood at this time.

*Palpatory Examination of Pancreas J W Grott—p 181

Palpation of the Pancreas—Grott found that if the patient lies on his back with the knees flexed and with a support under the lumbar portion of the vertebral column (either an arm or a sand sack, 8 or 10 cm in thickness), greater relaxation of the abdominal walls can be obtained. The patient is examined first without the support under the lumbar vertebral column and then the examination is repeated with this support. At the beginning of the examination the examiner places the right hand on the abdomen in such a manner that the slightly bent fingers reach the external edge of the left abdominal rectus muscle. The fingers of the right hand are used for palpation, those of the left hand to exert the necessary pressure. The patient is told to breathe deeply and quietly so as to effect complete relaxation. During a deep inspiration the fingers of the right hand pressed by those of the left go deep down into the abdominal cavity. When the greatest depth has been reached, the external edge of the left rectus muscle is pushed aside and an attempt is made to reach the side of the vertebral column with the fingers of the examining hand. The examination must be made slowly and with precaution so as to avoid any painful pressure, which might result in an erroneous interpretation of the palpation. A roentgenologic control of the examination disclosed that the stomach recedes in the direction of the epigastrium in the course of the palpation. The author assumes that the intestines are also pushed aside. He advises that the palpation be begun not in the region of the pancreas itself but rather in the adjoining regions. He begins below the line that goes through the umbilicus. If this is done the patient becomes accustomed to the examination and, when the pancreas is reached, he is capable of differentiating between the sensation produced by the pressure of the hand and by pain in an organ. This method permits the detection of a pain to pressure at the site where the pancreas crosses the lumbar portion of the vertebral column and the abdominal aorta. The forward bending of the vertebral column makes its lateral surface larger, and the pressure of the diseased organ against this hard support elicits the pain symptom. The author made this examination in 101 patients and palpation of the pancreas was possible in eighty-eight. Of the latter, thirty-two complained of pain, seventeen stating that the pain was severe and fifteen that it was mild. Further tests on the seventeen patients indicated that ten had a chronic inflammation of the pancreas, while in the other seven such a disorder could only be assumed.

Purified, Protein-Deficient Serums in Diphtheria—Hildebrandt points out that it is known that pseudoglobulin is the carrier of the antitoxin. This knowledge is the basis for the purification of the serums, in that attempts were made to eliminate the other protein fractions that do not carry antitoxin. It proved possible to produce therapeutic diphtheria serums the protein content of which does not exceed 5 per cent. Animal experiments with protein-deficient serums indicated that the rapidity of resorption is inversely proportional to the protein content. For this reason it was assumed that the serums with low protein content are of especial therapeutic

value, because they fulfil one of the most important requirements of successful serum therapy, namely, rapid resorption. The author decided to compare the efficacy of the serum that is deficient in protein with that of native diphtheria serum. Another factor that induced him to try this treatment was that the protein-deficient serum might be important from the point of view of serum disease. He employed the two types of serum in alternate cases of diphtheria that came up for treatment. He used the serums in fifty-eight and fifty-seven cases, respectively. In each group there occurred five deaths. A tabular report indicates that 28 per cent of the group of patients who were treated with native serum and 20.7 per cent of the group treated with protein-deficient serum developed signs of serum disease. This rather high percentage for both groups is explained by the fact that the symptoms of serum disease were carefully watched for, so that probably none escaped observation. A comparison of the severity of the symptoms of serum diseases in the two groups disclosed that in the patients who had been treated with the protein-deficient serum the symptoms were on the whole somewhat milder than in the other group. The author is as yet unable to render a definite evaluation of the therapeutic value of the protein-deficient serum, but he maintains that he saw nothing indicating its inferiority to the native serum.

Psychic Behavior at High Altitudes—Jongbloed investigated whether the oxygen deficiency would impair the alertness of an aviator flying at an altitude of 5,000 meters, pointing out that such heights occasionally are necessary when high mountains have to be crossed, particularly if cloudiness obscures the mountains. The alertness of the aviator is especially important in case of so called blind flying that may be necessary on account of the cloudiness. The author found that the rarefaction of the atmosphere at the altitude of 5,000 meters causes only slight impairment of the mental alertness in the radio telegrapher. He found that the slowing down of the mental alertness was most noticeable in the choice reactions, the regularity being influenced more strongly than the duration of the reaction time. However, the author is convinced that a trained aviator can safely fly for about an hour at an altitude of 5,000 meters but that a further increase in the altitude decreases the alertness rapidly and, for instance, blind flying during bad weather makes higher demands on the alertness of the aviator. Three of the author's test subjects had to breathe oxygen shortly after an altitude of 5,000 meters had been reached, while four others had difficulties. This indicates that at this altitude difficulties may be encountered in passengers, for, although the aviators can be selected in air transportation, the passengers cannot. Accordingly it is necessary to take measures so that air transportation will not cause difficulties even in the weakest of the passengers. The author states that an oxygen supply should be available for altitudes of more than 5,000 meters. However, he thinks that breathing-masks and other instruments are likely to alarm the passengers and should be avoided. He thinks that since the cabin of a modern plane has a regulable ventilation system, it would probably be possible to keep the oxygen tension high enough by forcing in a supply of oxygen.

Impairment of Heart by Roentgenotherapy—Parade says that in 1933 he called attention to exacerbations of thyrotoxic cardiac disturbances following roentgenotherapy of the thyroid. He reports the histories of two patients whom he observed recently and in whom roentgenotherapy was followed by disturbances in the cardiac rhythm. The first patient was a man aged 42, who had mitral stenosis and who was subjected to roentgenotherapy of the right lower field of the lung because of a suspected tumor. At first the irradiations given at inter-

vals of two or three days were well tolerated, but considerable acceleration of the pulse and severe arrhythmia developed a few hours after the last irradiation. Electrocardiography disclosed closed auricular fibrillation and absolute arrhythmia of the ventricles. The arrhythmia proved extremely refractory, it did not yield to treatment with large doses of quinidine, but later it was somewhat improved by digitalis. The second case was that of a woman, aged 58, who likewise had mitral stenosis and developed auricular fibrillation and absolute arrhythmia following the roentgen irradiation of a carcinoma of the uterine cervix. The anamneses of both these patients revealed that the mitral stenosis had caused practically no discomfort previous to the roentgenotherapy. In view of the fact that the arrhythmia developed in both patients immediately after the irradiation, the author assumes a connection between the two. It is noteworthy that in the one patient the heart had been directly exposed to the rays, whereas in the second case the action must have been indirect. The author assumes that substances liberated in the course of the roentgenotherapy might exert their harmful effect on the heart or on the centers regulating it. He cites the case of a woman with polycythemia rubra, in whom the long tubular bones had been irradiated with roentgen rays and who had developed a threatening auricular flutter. This case was somewhat more complicated in that the flutter responded to quinidine treatment, but ten days later a fatal coronary thrombosis developed. The author concludes that great precaution is necessary if roentgenotherapy is employed in patients with heart disease.

Staphylococcal Infection of Leptomeninges—Ghon and Mittelbach describe a case of staphylococcal meningitis which is noteworthy because of its macroscopic and histologic aspects. The case had been diagnosed clinically as meningo-encephalitis and cardiac and aortic defect. The primary disorder had been an ulcerous endocarditis, and death was caused by septicopyemia. Histologic examination of the brain disclosed recent meningo-encephalitis with abscess formation. The majority of the abscesses contained bacteria either in the form of emboli or in clumps free in the tissues. Evaluation of the various aspects indicates that the process was a septicopyemia caused by *Staphylococcus pyogenes-aureus* which originated in a recurring, ulcerous-polypous endocarditis of the aortic valves and led to hematogenic metastases in the liver, kidneys, spleen, epicardium, brain and leptomeninges. The case is especially noteworthy because of the anatomic aspects of the leptomeninges, which contained small and miliary abscesses with hemorrhagic areolas at the convexity of the cerebrum and in the cerebellum. With the exception of small hemorrhages in the cerebellum, which indicated encephalitic foci, the brain was free from encephalitic signs. The author is convinced that the abscesses in the leptomeninges are hematogenic metastases of the endocarditis. This form of hematogenic, metastatic infection of the leptomeninges is unusual and for that reason noteworthy, for the metastatic infiltrations of the brain in case of acute infections usually appear in the form of abscesses in the cortex and medulla. The reported case contradicts the statement of Spatz, according to which the meningitic foci develop as the result of the encephalitic ones, that is, secondarily, for the histologic aspects of this case justify the assumption that the encephalitic foci were caused by the leptomeningitis either by direct transition or by way of the vessels and possibly also partly by the hematogenic route from the endocarditis.

Basal Metabolism During Pregnancy and Preeclampsia—Dietel shows that the basal metabolic rate is increased in the majority of pregnant women and that this increase disappears again during the puerperium and remains constant after it. Thyroid substance or its preparations are incapable of further increasing the heightened basal metabolic rate of

pregnant women. It is probable that the thyrotropic hormone of the anterior lobe of the hypophysis plays an important part in the heightened metabolic rate during pregnancy. In preeclamptic patients the basal metabolic rate is lower than in normal pregnant women, but it is impossible to compensate for this reduction by the administration of thyroid substance or of thyroxine. These observations show that the actions of thyroid preparations, particularly their effect on the basal metabolism, are reduced during pregnancy and preeclamptic and eclamptic conditions. The author points out that this explains the high tolerance for thyroid preparations in healthy pregnant women and in those with preeclampsia. He says that this resistance to thyroid preparations is being further investigated in order to find a better treatment for the preeclamptic conditions.

Histology of Tumors of Breast—Limburg shows that in the great variety of histologic pictures of mammary tumors there are borderline cases that stand between benign tumors and malignant ones. At his clinic thirty-two such cases came under observation (in addition to 784 unsuspected cases) within the last ten years. He describes eighteen cases in which the histologic examination of the exploratory excision did not permit a definite prognosis. Only three of these patients were subjected to a radical operation (amputation of breast and removal of axillary glands), but all were kept under clinical observation and during a period of from one to six years all remained free from relapse. In view of this observation and although he is aware of the fact that the number of cases is rather small, the author thinks that a malignancy index of from 25 to 50 per cent is too high for cases of cystic breast and that the epithelial proliferations do not deserve the unfavorable estimation to which they are generally subjected.

*Does Cancer Mortality Increase? H. Schwarz—p. 426

Bacteriotherapy of Tar Cancer—After calling attention to previous studies with colon bacilli, Peretz and his associates describe further studies which they made on sixty-two mice with tar cancer. Observations made in the course of these studies on the treatment of tar cancers with coli agar revealed that (1) in a number of cases this treatment cleanses the cancer wound surface, inhibits the crust formation and prevents suppuration, (2) occasionally it produces a certain inhibition of the growth of the tumors, (3) it seems to prolong the life of the mice with extremely large tumor wounds. Studies were made also on the microflora of the tar cancer and on its modification by the coli therapy. Tests that were made before the onset of the bacteriotherapy revealed in many cases streptococci and staphylococci, in some cases *Bacillus proteus* and in others sporogenic bacteria. However, the most frequent microflora were gram negative organisms that belong to the coli group. The authors refer to them as the "tar cancer bacilli." Tests made in the course of the coli therapy revealed that it counteracts to a great extent the staphylococci, streptococci, sporogenic bacilli and other microbes but that it exerts only a slight influence on the "tar cancer bacilli." Experiments *in vitro* corroborated these observations. In further studies they attempted to find an antagonist to the "tar cancer bacilli," but without success for the experiments proved that coli therapy represents the most effective antagonist. Attempts to counteract the resistant "tar cancer bacilli" with a polyvalent antiviral failed likewise. In summarizing their observations, the authors reach the conclusion that the favorable action of coli therapy on tar cancer is due to the fact that it vigorously counteracts the staphylococci, streptococci and other micro-organisms and that it influences the "tar cancer bacilli" at least slightly. They hope that coli therapy will eventually be applicable in human beings, particularly in those with cancer of the intestinal tract.

Cancer Mortality—Schwarz analyzes the cancer statistics of Czechoslovakia, which indicate a great increase in cancer

mortality in recent years. He shows that this increase is apparent rather than real, it being accounted for partly by the predominance of the higher age groups and partly by the fact that a larger number of cancers are now recognized than was formerly the case. The importance of the latter factor is proved by the fact that the increase in cancer mortality is especially great in the eastern portion of Czechoslovakia, where formerly lay persons gave the cause of death in a larger number of cases than is the case today. As this part of the country becomes better supplied with physicians and hospitals, cancer is more often recognized as the cause of death. A comparison of the cancer statistics of recent years with those of the previous ones indicates that the increase in mortality from cancer is largely explained by the decrease in such diagnoses as death from "old age" and from other indefinite causes.

*Operative Treatment of Appendiceal Peritonitis Without Drainage. M. V. Krasnoselskiy—p. 193

Time of Operation in Acute Appendicitis—Krasnoselskiy studied 1,944 cases of acute appendicitis from the point of view of operative indications at various stages after the onset of the attack. The study of the pathologic alterations in the appendix demonstrated that neither the time elapsed since the onset of the acute attack nor the clinical picture made it possible to estimate the underlying pathologic condition of the appendix and of the adjacent structures. The prognosis cannot be established with any degree of certainty on these data. The author therefore believes that operation is indicated as soon as the diagnosis is made, regardless of the time elapsed or of the degree of severity of the clinical symptoms. Conservative treatment is permissible only in cases with well defined palpable induration, provided the patient is kept under observation in the surgical division. The incidence of acute appendicitis in women was less than in men. It ran a milder course and its mortality was about one third that occurring in men. The deciding factor in mortality was not the time element and the consequent loss of immunobiologic properties of the organism, but the pathologic alteration in the appendix and the surrounding structures. Comparison of a series of 500 cases up to January 1933 with a series of 1,444 cases from Jan. 1, 1933, to July 15, 1934, showed that the mortality was lowered from 3.2 per cent to 1.8 per cent. The mortality for the two series was 2.16 per cent, 3 per cent in men and 1.12 in women.

Indurative Stage of Acute Appendicitis—Stuchinskiy analyzed the 172 cases of appendiceal abscess occurring in 1,944 cases of acute appendicitis admitted to the Leningrad Institute for Quick Aid. Of these 54 per cent occurred in women and 46 per cent in men. The average day of admission for cases complicated with a tumor was the sixth. The causes for tardy reference to the hospital were (1) delayed or erroneous diagnosis in 33 per cent, (2) attempt at conservative treatment at home, because of an impression that surgical intervention was not indicated, in 32 per cent, and (3) refusal of hospitalization or operation in 30 per cent. Patients admitted to the institute in the stage of tumor formation were treated conservatively. In the absence of signs of peritoneal inflammation the treatment was limited to rest and the application of heat. Spontaneous absorption of the induration took place in 141, or 83 per cent of the cases, usually on the twelfth to the thirteenth day. In twenty-seven the induration went on to suppuration. Operation was performed in these cases. It consisted of incising the abscess and draining without opening the peritoneal cavity or attempting to remove the appendix. There were three fatalities among the 172 cases (1.7 per cent). The follow-up study for the next two years revealed 32 per cent of recurring attacks. Emergency operation was performed in 18 per cent. Because of persistent pains, 14 per cent of the patients were

operated on in the cold stage. The examination of the removed appendixes showed that this structure persisted in 97 per cent of the cases. The author therefore believes that the appendix should be removed in the interim stage following the recovery from an appendiceal abscess.

Acute Appendicitis in Children—Of 140 cases of acute appendicitis in children reported by Shaak, 58 per cent were in boys and 42 per cent in girls. Acute appendicitis in children runs a more severe course than in adults and gives a higher mortality. The total in this series was 8.5 per cent, for cases of later stages it ranged from 16 to 20 per cent. The younger the child the more serious the prognosis, the mortality for those less than 3 years of age amounting to 20 per cent. The pathologic alterations in the appendix and in the peritoneal cavity develop with great rapidity, and perforation may occur earlier than twelve hours after the onset. The diagnosis in young children is difficult, and errors are more frequent than in adults. Pneumonia furnishes a high percentage of diagnostic errors. The operative indications are the same as in adults, the insistence on an early operation, however, must be even more urgent here because of the rapid progression of the process. The author advocates operative intervention in any stage of acute appendicitis, even after forty-eight hours, if the symptoms are not abating.

Treatment of Appendiceal Peritonitis Without Drainage—Krasnoselskiy analyzed the 1,944 cases of acute appendicitis in which operation was performed in the Leningrad Institute for Quick Aid between May 1932 and July 1934 with especial consideration of the results obtained with the method of closing the peritoneal cavity without drainage. He shares the view of many authors that the general peritoneal cavity cannot be drained and that therefore the drain is superfluous and at times injurious. If the appendix has been removed the bleeding arrested and peritonization complete, there exist no indications for drainage. This postulate is not influenced by the character of the exudate, by the existence of gangrene or perforation of the appendix, or by the time elapsed since the onset of the attack. Local drainage with the view of isolating the focus of infection from the rest of the peritoneal cavity is indicated in the presence of a suppurating area denuded of peritoneum, in failure to remove the appendix, in improperly carried out appendectomy, or in the presence of a raw, oozing surface. In a series of 950 cases of purulent appendicitis 98 per cent were closed without drainage. In a series of 360 cases of gangrene or perforation of the appendix, 67 per cent were closed without drainage. The percentage of drained cases in a total of 1,330 severe purulent appendicitis cases was 10.5. With regard to the character of the exudate, local drainage was practiced in 37 per cent of the seropurulent type, in 30 per cent of the purulent and in 54 per cent of the cases with abscess formation. Residual abscesses were less frequent when drainage was omitted. The incidence of abscess of the pouch of Douglas in the series in which drainage was not practiced was 3.3 per cent while in the series in which it was practiced it was 7.8 per cent. Abscess on the left side was seen in 0.34 per cent of the cases in which drainage was not done and in 2.16 per cent of the cases in which drainage was done. There was only one case of subdiaphragmatic abscess, and that occurred in the drained series. Mortality in the series in which drainage was not practiced was 1.5 per cent, while in the other series it was 17 per cent. The analysis of the twelve fatalities occurring in the series in which drainage was omitted shows that only seven patients died as the result of spreading peritonitis that was already present at the time of operation.

*Familial Occurrence of Chronic Suppurative Coloproctitis. O. Moltke.—p. 343

*Hyperproteinemia (Late Diagnosis of Myeloma: the Formol Gel Reaction, Bence Jones Proteinuria and Kidney Lesion). Case. J. Bing.—p. 354

*Hyperglobulinemia with Disturbance of Central Nervous System on Toxic Infectious Basis (Myelitis Polyradiculitis Changes in Spinal Fluid). Two Cases. J. Bing and A. V. Neel.—p. 369

Chronic Suppurative Coloproctitis—The malignant (ulcerous) form of this disorder appeared in two of the five families described by Moltke, and a more benign form in the

other three. He says that familial occurrence of the disorder is suspected in four additional families, but verification of the diagnosis has been impossible for various reasons. Transmission by infection from one member of a family to another is regarded as quite improbable in most cases of suppurative coloproctitis.

Hyperproteinemia—After repeated examinations, myelomas were finally demonstrated in one of Bing's three cases of hyperproteinemia, in patients aged from 56 to 59, but could not be confirmed roentgenologically in the other two. In the second case the diagnosis was verified after sternal puncture and on necropsy. The third patient continues under observation. The hyperproteinemia, in all cases a hyperglobulinemia, was indicated by a marked increase in the sedimentation reaction (from 75 to 159 mm in one hour), and the formol gel reaction was positive in these cases but negative in serum from normal patients and patients with other disorders. There were renal lesions in all three cases with elimination of large amounts of Bence-Jones protein in one case. Examination of the relative albumin percentage in the urine containing Bence Jones protein showed considerable variations depending on the total protein content, and the proteinuria varied with the creatinine clearance independently of the diuresis, as previously shown in ordinary proteinuria and cholesterolemia.

Hyperglobulinemia—Bing and Neel describe two cases of marked hyperglobulinemia associated with pronounced changes in the central nervous system, such as myelitis and polyradiculitis, and changes in the spinal fluid. The patients subsequently evinced a high rate of erythrocyte sedimentation and a positive formol-gel reaction. Infections were present in both instances. The authors assert that these cases present a picture not previously reported.

*Puncture of Bone Marrow with Especial Reference to Bone Marrow in Pernicious Bothriocephalus Anemia. G. Totterman.—p. 547

*Grave Pseudoparalytic Myasthenia in Child Aged 2. L. Grönlund.—p. 559

Puncture of Bone Marrow—Totterman considers Annkin's method for intravital examination of the bone marrow the simplest procedure and uses it. In a typical case of cryptogenic pernicious anemia the bone marrow punctate was characterized by marked increase in the nucleated red blood corpuscles, 286 to 400 white, a large part consisting of promegaloblasts and megaloblasts. The number of reticulocytes in the punctate was the same as in the blood. In two cases of pernicious bothriocephalus anemia the bone marrow showed changes similar to those in the case of cryptogenic anemia, the resemblance between these two forms of pernicious anemia thus extending to the changes in the bone marrow. The difference between the blood and the bone marrow pictures in a case of chronic lymphatic leukemia and one of untreated chronic myeloid leukemia was slight. In a patient with a low leukocyte count in the blood more than 90 per cent myeloblasts were demonstrated in the bone marrow, after some weeks the blood presented the typical picture of acute myeloid leukemia.

Pseudoparalytic Myasthenia in Child—Grönlund says that the characteristic symptoms of ptosis and strabismus marked the onset in this case, and the chronic course, remissions, aggravation after five months with difficulty in chewing and swallowing, weakness in the muscles of the neck, indistinct articulation and greater intensity of the symptoms in the evening than in the morning pointed to a typical myasthenia. Three months' hospitalization with rest in bed for about two months and general strengthening treatment resulted in improvement. The history of occasional strabismus on the part of the child's father and brother afforded the only suggestion of a constitutional etiologic factor. The low values found in the sugar loading and epinephrine tests point to a disturbance in the carbohydrate metabolism and tend to support the hypothesis that the cause of myasthenia depends on disturbances in the endocrine system.

MONTREAL

Let it be stated that this work is far from completion some parts are quite clear in my mind, others are still nebulous, and do not as yet fit perfectly into the scheme of things. For the last reason, it is thought that the whole truth has not been grasped. This applies not to the observed facts, which are irrefutable, but rather to the interpretation that has been put on these. This criticism applies more especially to the pathology of the placenta—a new, almost virgin, field. A good deal has been written about the physiology of the placenta, but of the pathology there is next to nothing. This study will cover a most intensive application to 1,000 placentas, described in detail immediately after birth, then labeled and hardened for six weeks. These are then cut into slabs of 1 cm thickness, each slice is critically examined with a magnifying glass, and blocks for microscopic study are cut from these. The total will cover about three to five thousand slides. The clinical history is appended to each placental description, for study of relationship of pathologic changes and clinical signs. These 1,000 cases, of which 750 are completed—the other 250 are reserved for more intensive study—are consecutive hospital cases, normal and otherwise. The clinical study, on the other hand, comprises research on about 300 cases of toxemia of all grades of intensity. Lastly, an endeavor has been made to correlate clinical pathologic observations with placental disease. Here is the weak link, as yet quite incomplete, still nebulous, requiring careful circumspection and slow speed. Let me repeat, this is an incomplete report, subject to minor, perhaps some major, changes as new discoveries are made.

CLINICAL STUDIES

It is commonly taught that toxic cases in pregnancy fall into two great categories (1) the preeclamptic and (2) the nephritic. Let me most emphatically state that this is wrong. There is but one toxemia of pregnancy, and all cases fall into that group. Only the preeclamptic are being dealt with, and these should be spoken of as cases of toxemia of pregnancy, and not as preeclamptic. All cases of toxemia are potentially eclamptic, but not all of them are preeclamptic.

But what has led to this erroneous subdivision of cases into preeclamptic and nephritic is the hitherto unrecognized facts that, like all other diseases, toxemias are either (1) acute or (2) chronic, and these two groups differ so markedly in clinical picture and pathology that the connection has been overlooked. The chronic cases resemble the nephritic but are not nephritic, and when nephritis or kidney damage antedates a pregnancy, these cases ought to be spoken of as a nephritis complicated by a pregnancy, just as a heart or other diseased system may be complicated by a pregnancy. The clinical characters of acute cases will differ according to the organs that have to bear the brunt of the toxic attack, whether it be liver, kidneys, nervous system or gastro-intestinal tract, and those organs will show the first and perhaps the most dominant symptoms, which possess a low reserve, or an idiosyncratic weakness for that specific poison. So that whether the clinical picture of the toxemia is the so-called renal or hepatic or neurotrophic or vascular extravasatory is not due to different primary or intermediate causes but to individual system instabilities arising out of a low reserve, combined with the intensity and the duration of the toxic attack.

In acute fulminating toxic states, the systems have not time to adjust themselves to the sudden development of the toxemia. As a consequence, the symptoms differ as markedly as do those of acute from chronic infections. The chronic toxemias, on the other hand, present a very protean symptomatology, and the reason why these cases rarely pass into eclampsia is that the time element allows for the development of cell accommodation and for increased tolerance on the part of the autonomic nervous system. The mass group of chronic cases can be classified more or less according to their symptomatology, and, what is much more important, much can be gathered that permits one to form some opinion of the danger to both mother and fetus.

1 A group of chronic cases in which the only sign of toxemia is a very large quantity of albumin in the urine, with or without casts. The albumin may be as high as 12 Gm to the liter. It is not a matter of indifference whether casts are present or not. Into this further refinement I cannot enter here. But the total absence of symptoms and other signs is striking. These cases offer very good risks. Rarely do any serious damages to either mother or child develop. The placenta rarely shows any serious changes that might jeopardize the life of the fetus. The patients often wonder why so much concern is shown for them.

2 Cases similar to the former group but showing an elevated blood pressure. Here also there is a total absence of symptoms. In this group the prognosis of both mother and child depends more on the blood pressure than on the amount of albumin. In a percentage

of these, as in all toxic cases, the history of blood pressure before or in the early months of pregnancy may permit one to determine whether the pressure is due to the pregnancy or to some cause outside and antedating the pregnancy. It is only by watching cases from the early months, studying them in retrospect, that one can arrive at any differentiation. The prognosis varies with the blood pressure, and there is grave danger to both mother and fetus.

3 Cases without any symptoms whatever except a rising blood pressure and a progressive pallor. There may or may not be albumin and casts. In the majority of instances these are absent or intermittent. These are dangerous cases, with a doubtful prognosis for the mother and a bad prognosis for the child. The mother's future may be judged by the past observations and by the duration and intensity of the blood pressure. The life of the fetus is always a doubtful quantity, owing to the frequency of associated placental disease. The outcome for the fetus may be death in utero or intra partum, or the birth of an octogenarian.

All the foregoing have been symptom free.

4 Those with general or local edema and a normal blood pressure. These are relatively rare and are mostly found in twin pregnancies, and, as a rule, the prognosis for mother and child is good.

5 A group with edema, high blood pressure, albumin and casts, with nerve center symptoms such as headache, flashes in the field of vision, frosted glass visibility and intractable neuralgias. The prognosis for mother and child is poor if pregnancy is not soon terminated. The children often succumb. This is the common neutrotropic type, dangerous at the moment, and often leaving a train of nervous symptoms and ill health afterward.

6 A series with high blood pressure, gastro-intestinal disturbances, epigastric pain and possibly jaundice. Albumin may be large in quantity, with casts and a variable quantity of bile in the urine. The prognosis is bad, and unless the pregnancy is soon terminated, either spontaneously or artificially, the outcome will undoubtedly be serious.

These, of course, are more or less arbitrary lines of division, but they conform rather closely to types.

HEMATOLOGY

About 200 cases of toxemia have been examined by Dr. Rudolf Gottlieb and myself. In most of the cases of toxemia, even in the early stages before symptoms or clinical signs have developed, there can be demonstrated a definite shift to the right in leukocytes, such as one finds in many of the endocrine dyscrasias. The leukocyte count in pregnancy, normal and otherwise, is elevated to 10 to 12 thousand, owing chiefly to neutrophils, and in cases of advanced placental disease and necrosis this is shown in the blood by a definite microcytosis. But by far the most important change is found in pregnancy in the lowering of the hemoglobin coefficient. It has been found that the falling off of the hemoglobin content of the red blood cells (which by the way, do not show a corresponding reduction in number) begins rarely before the fifth month and is progressive from that time on. This is a true hypochromic anemia, and of the 300 cases that have shown this condition nearly every one has either a total, or nearly total, absence of gastric hydrochloric acid. This hypochromic anemia is particularly marked in cases in which the pregnancies have followed one another in rapid succession. In the young, and in those with few pregnancies, the hydrochloric acid begins to return post partum, before

the patients leave the hospital. In the graver cases, with multiple pregnancies, the return is much retarded or may be incompletely restored or totally and permanently absent. The interesting sequence is this: that these cases respond rapidly to huge doses of iron, and as their blood equation is restored, many of the symptoms, such as numbness of the forearms after sleep, muscular cramps, headaches and neuralgias, disappear rapidly, almost magically. I think it also a fair inference that the incidence of toxemia will be greatly reduced by raising the quality of the blood, and consequently also of the cells and function, to normal or nearly to normal, for the tissues cannot be healthier than the blood, and normal blood and normal tissues presage normal function.

When, on the other hand, one comes to a consideration of blood chemistry in relation to toxemia, the situation is constructive. In all, several hundreds of all grades of chronic toxemia have been studied, and one is forced to the conclusion that blood chemistry is almost labor lost. The reports come back in the gravest chronic cases without any signs of retention, except in the gravest true chronic nephritic, not true toxic, cases. The urea, nonprotein nitrogen, carbon dioxide capacity, van den Bergh test and uric acid content usually vary within the normal limits, except perhaps the uric acid content, which frequently is high but seems to have little, if any, clinical significance. The statement that a concentration of uric acid over 6 per cent is indicative of an impending eclamptic seizure is certainly not in conformity with our large experience. There seems to be a relationship between a high uric acid content and low blood sugar estimation, but this again seems to have slight or no prognostic value.

In cases of true nephritis, blood chemistry may be of inestimable value, but chronic toxemia is not nephritis. Would there not be more rational signs if one were dealing with nephritis? In all my cases there was but one case with signs of nephritis in the ocular fundi. The fundi are singularly free in chronic toxemia. The most one sees are occasional small hemorrhages and, in serious cases, edema of the disk. I purposely requested that these cases be examined by one man, a senior ophthalmologist in McGill, in order that the individual equation might be eliminated. Homatropine was used in every case so that there could be no mistake.

Moreover, I have already published reports of five cases of chronic "nephritis" cured by pregnancy—cases of true nephritis, if one can trust the symptoms and signs of nephritis as interpreted by professors of medicine in McGill. The patients had been hospitalized for a time and every known test performed, and had been under observation from two to five years. They were advised against pregnancy, but they took their courage in their own hands and today, after one or two pregnancies, are free from high blood pressure, albumin and casts—in fact, normal healthy individuals. It prompts the important question: what is nephritis? Several cases have been added to the list by my colleagues since my publication.

What, then, are the renal types of toxemia of pregnancy?

I am not prepared as yet to give an answer to that question. There are many more years of study ahead on the subject. But the vast majority of them are not nephritic when they appear so. Any deranged function, if sufficiently prolonged, will lead to progressive chronic organic changes, and that is the whole crux of this difficult problem. It is intensity and duration—but

chiefly duration—that lead to permanent organic disease. How long can deranged function persist without organic disease? The answer is that they are synchronous in operation, but functional dyscrasia may have to persist for quite a period and be of a certain intensity before the organic lesion becomes recognizable by our imperfect methods of examination. Hence the necessity of removing the cause as early as possible to reduce intensity and duration.

What is the cause of toxemia of pregnancy? I think it is an endocrine dysfunction. I published the study of the subject over a year ago. The reasons were as follows:

Pregnancy causes more change in the endocrine systems than in any other organs except the uterus. That is generally admitted today. The ovaries, thyroid, pituitary, pancreas, bone metabolism frequently all undergo marked alterations in pregnancy. In the majority of instances these changes usually retrogress when the pregnancy ceases. But occasionally pregnancy initiates a continuous train of endocrinologic sequences that are persistent, often permanent and progressive. That spells eventually progressive organic lesions. What glands are mostly at fault in toxemia? The major part of the blame would seem to lie with the posterior pituitary. The posterior pituitary has been shown to contain at least three ingredients which control uterine action, water balance, and blood pressure. Other glands of internal secretion have a profound effect on blood pressure also and may be incriminated with the posterior pituitary. Doubtless this is frequently the case, because endocrinologic dysfunctions are seldom uniglandular but mostly plurglandular. In two cases of death following eclampsia I have been able to demonstrate unusually large pituitaries. These as yet have not been serially sectioned, but enlargement is not necessarily an accompaniment of increased function.

The whole danger, not in relation to life but in relation to organic disease, lies in the persistence of the dysfunction after the pregnancy has ceased, and this persistence is almost proportionate to the duration of the dysfunction in the pregnancy. Naturally intensity plays a large part also, but not to the same extent. These last two statements are so important and regular in their application that they might be put into the form of an axiom.

Toxemia considered from an endocrinologic etiology can be explained logically and that hypothesis as to its etiology gives us a rational instead of an empirical understanding of its treatment. By the endocrinologic hypothesis a ready explanation can be found for the cure by pregnancy of so-called nephritis, and for the incidence of organic lesions following chronic toxemia.

For an explanation of the cures of chronic nephritis one has to study a graph of another gland, the thyroid. Its secretion is complex, like that of the pituitary. Its symptomatology is consequently complex, and the organic lesions that follow its prolonged hyperactivity are not the direct result of the gland overactivity but of metabolic dysfunction which it entails. These organic lesions are proportionate with the duration of the gland dysfunction but also with its intensity. So it is with the posterior pituitary: the remote effect of the overstimulation of these glands by the pregnancy will depend in the last analysis on the reserve of the affected gland. So that the intensity and duration of the impulse, on the one hand, and the sensitivity and reserve of the glands on the other, determine the lightness or severity of the reaction, as well as its duration and after-effects.

It must be well understood that every function of the body is under control of some gland of internal secretion and that the pituitary seems to occupy the position of a master gland, like the master machine in large industrial plants, which controls the rate of operation of all minor machines.

The study of the metabolic changes that occur in the body as a consequence of acute or chronic toxemia may furnish data that have a bearing on gravity and outcome but can never lead to a discovery of the causation, any more than an estimate of glycemia or of the organic changes that follow on it can give an inkling of the causation of diabetes. The renal, hepatic, gastrointestinal, cardiovascular changes of toxemia are merely consequences, not causes, and a study of these will give a clearer picture of the effects but not of the underlying primary agent or agents.

PATHOLOGY OF THE PLACENTA

A good deal has been written on the physiology and permeability of the placenta, but its pathology is almost a closed book. It has been my great privilege to turn over just a few pages. Seven hundred and fifty placentas taken consecutively have been subjected to careful study. Some knowledge has emerged from this. May I repeat that the statements I am about to make are facts not open to question, their interpretation is still decidedly questionable, requiring a great deal of atmospheric clearing before clear visibility is attained. One of the most striking facts is that placentas begin to degenerate at or about the seventh month, and that a normal healthy placenta at full term is a rarissima avis, so rare as to be almost nonexistent. The placenta at full term is a museum of pathology, in which the most startling and *suu generis* changes exist. Naturally these vary in degree in different placentas and at the various months of the third trimester. But, generally speaking, these degenerative changes are universal though varying in degree. This study has led to this understanding: that the placenta has a history like any other form of life. It has its embryony, its infancy, its adolescence, its maturity, and its senility. Interest lies chiefly in the end product. Generally speaking, decay begins about the seventh month and is progressive, though not necessarily so, and in this degeneration the placenta is not only frequently, but even liable—and more than liable, owing to its senility—to be overtaken by other disease processes, and it becomes one of my most difficult problems to separate senile changes from those of true organic pathologic changes. It will require years of intensive study to clear this field.

A question naturally rises to the mind. Why should placental degeneration occur when its full function has not been fulfilled? Let us go further. Why should degeneration occur when the fetal demands are still increasing? To the casual observer, this is an irrefutable statement. But it is a superficial view only of conditions. In early embryonic life the rate of life is greatly accelerated, and this rate gradually slows down throughout fetal life and throughout life in general until the end of senility. Therefore, fetal demands, cellularly speaking, grow less and less as intra-uterine term progresses. True, the number of fetal cells to be fed grows, but their appetites are smaller. But a much more important fact lies in this, that in the early stages of fetal life the embryo depends on its mother for all its needs. Differentiation has not yet occurred, and function, except the most essential, cardiac, has not yet been established. Later, when cell differentiation is complete, not only can the fetus supply most of its own

needs, but it may elaborate in excess to supply a deficiency in the parent—a reverse current, as it were. So that at the end of fetal life the placenta is merely the transmitter of oxygen and partly assimilable food, and the clearing house of products of fetal metabolism—almost a dialysis. Lastly, in placental function nature follows her general rule in doing things abundantly. The placenta normally is an organ with at least 75 per cent reserve. This to me was an astonishing finding, that a child in utero could live on less than 25 per cent of its full placental capacity. But my surprise diminished when I thought of nature's care for the species, and it ceased completely when I learned from our physiologists that the young healthy child calls on only about 40 per cent of the functional capacity of its organs. If this is the case in postnatal life, how much more must this be true in fetal life, when body heat production, food search, food effort and food elaboration are reduced to a minimal denominator—in fact, when energy expenditure is reduced to the lowest possible degree. For let it be well understood that the mechanical destruction of food products is all in the column of expenditures, whereas the chemical destruction of higher products to the lower is all in the column of energy generators. With the former, the fetus has nothing to do, the mother does all that part of the mechanical expenditure for her offspring. It has only to do with the function of chemically breaking down higher standards to lower, from which it probably derives most of its energy. That implies fetal function. Are we to suppose that fetal function starts only in postnatal life? On the contrary, birth is just an incident, life is just a continuation in a new medium. Birth is just a transition—a transition from an aquatic to a terrestrial life, with internal changes to allow easy accommodation. So we see that the function of the placenta diminishes as fetal life advances, and that therefore degenerations of that organ are in keeping with its diminished activity. In a word, in the last months of pregnancy it has already fulfilled its greatest function.

As yet, I cannot separate senile changes from those of active organic disease. That is for the future. But it can be stated that that which is consistently found in all placentas, though perhaps varying in degrees, must be degenerative and not active disease. But here again a disturbing factor is found. As pointed out by my colleague Dr. John Fraser, it is not improbable that a senile placenta is much more vulnerable to abnormal circumstances than is a placenta in the full bloom of functional activity. This interesting suggestion is quite true—true not only in the placenta but also in all forms of living matter.

What are the chief pathologic placental changes?

Roughly, in order of their frequency, placental pathologic changes are as follows:

- 1 Chorionic sclerosis and subchorionic degeneration
- 2 Placentosis
- 3 Placental hemorrhages
- 4 Infarctions (so called)
- 5 Placental degeneration cysts

In the space at my disposal I can spend but a few words on each of these.

Chorionic Sclerosis and Subchorionic Degeneration—A description of these changes—the fibrin deposits which spread from the fetal vessels like a lymph in response to maternal toxemia, the subsequent condensation of this, the sporadic deposit of lymph about a maternal node to constitute milk spots, the slow con-

striction of the deposits about the fetal blood vessels as they pierce the chorionic plate, the consequent subchorionic degenerations and diffuse blood extravasations—offers one of the most interesting chapters in human pathology.

Placentosis, a New Disease—The second most common disease of the placenta may be acute or chronic, massive or spreading, and runs a course closely resembling pneumonia in its gross but not its microscopic appearance. I can give but a sketchy outline of this common disease, heretofore unrecognized. In the very acute form of massive placentosis, the placenta is almost black and almost diffuent. When cut anywhere in the fresh state, the placenta oozes a pool of very black blood, on section, cavities filled with blood abound. The fetal vessels stand out turgidly engorged. The placenta also is turgid, giving it a firmer consistency than normal, the cotyledons swollen and rounded as if under tension. After hardening for from four to six weeks, the placenta cuts like liver tissue and is blue black on the cut surface, numerous hemorrhages are seen varying in size from millet seeds to large extravasations. The thickness of the placenta may be increased to 2 and even 3 inches. To this stage of the disease, owing to its resemblance to acute pneumonia and to liver tissue, I have given the name of "red hepatization of the placenta."

When massive and of great intensity, it will eventuate in a complete "infarction" of the placenta, and death of the fetus usually occurs between two and three days after the acute onset. This eventually, if not cast off immediately, gives place to a large white fatty degenerated placenta. If, on the other hand, the intensity is not so great or of long duration, recovery may take place. In this process the placenta presents the gross characteristics of a lung undergoing gray hepatization. The cotyledons become discrete, giving rise to an alveolar arrangement. The alveoli are separated by soft degenerated maternal decidual tissue, and the center of each alveolus usually shows a hemorrhage of various size. The whole placenta may be uniformly affected, but in many instances certain portions may be affected more intensely than other parts. Under these circumstances a fraction of the placenta may die, giving rise to a large infarction, whereas the rest of the organ may recover and eventually hypertrophy. The hypertrophy is always most marked in the parts most remote from the infarction. Absorption of the infarcts is always by a fatty degeneration, and cavitation, even to the size of walnuts, is common in the infarcted areas. These vomicae are usually filled with detritus. In the cases of chronic placentosis one has the same process at work, but it varies in intensity, and repair processes in one part of a placenta may synchronize with creeping destructive processes in another. The differences may be due to the life in the uterus of the attached placenta. This has been carefully studied in twin pregnancies and in cesarean sections. Placentosis is not a result of labor, because it is found to be as frequent in placentas obtained from selected cesarean sections.

Infarcts arise in other ways, but time will not permit me to enter into this subject. Hemorrhage is the third most common pathologic entity of the placenta. It is almost an invariable accompaniment of placentosis and occasionally appears without the disease. The vast majority of hemorrhages of the former type are centrally placed in the cotyledons, but many hemorrhages, of a toxic origin, also arise in the degenerated maternal tissues. The interesting fact is that placental hemor-

rhage is common, occurring in four out of five cases, and the still more interesting fact that of the 600 hemorrhagic cases in my series there were only eleven that presented symptoms that permitted a clinical diagnosis.

Placental degeneration cysts occur in about one case in three, when present, they are usually very numerous and vary in size from an almond to microscopic dimensions. They always occur in the maternal decidual tissues and are therefore always found between the cotyledons or in the subchorionic areas. They have no clinical significance except as an expression of the degree of degeneration of the maternal tissues. Their mode of formation consists primarily in a tremendous swelling of the decidual tissues by a hyaline deposit, and later a liquefaction spreading outward from the core. Their content is always a clear blue-green jelly, except when discolored by hemorrhage, which is not infrequent. The walls of the cysts are made up of decidual cells in various stages of hyaline degeneration. Most bizarre ghosts of these cells frequently ornament the jelly center.

CLINICAL SIGNIFICANCE

What is the clinical significance of all this? There is a very distinct connection between these placental diseases and clinical toxemia of pregnancy. What that connection is, I am unable at present to venture an opinion. Whether the placental disease is a sequel to toxemia or whether the toxemia is a result of placental disease is a problem of the first magnitude. Suffice it to state at this juncture that the relationship is intimate. But there is another interesting feature, and that is that there seems also to be an equally subtle connection between placental disease and the onset of labor.

If the theory is accepted that toxemia is the expression of a metabolic upset consequent on an endocrine dysfunction, the treatment of toxemia of the last few years becomes rational instead of empirical. It consists in blocking the nervous system until the primary exciting cause of the acute toxemia—namely, the pregnancy—can be removed. But it is the chronic cases that interest me most. Acute toxemias have almost been eradicated by close observation in the antepartum clinics. But chronic toxemias are as numerous as ever, and the attitude toward these cases in recent years has undergone a marked change. One is no longer justified in multiparas, with living children, in driving the mother to carry on to the end of her pregnancy. I have found that the longer the toxemia has lasted in the pregnancy, the greater is the tendency for the signs to persist when the pregnancy is over. And the converse is equally true. In primiparas, the risks should be clearly pointed out to the prospective mother, and she should have the last word in deciding her course.

The categories previously laid down, though far from being decisive, will often help in deciding on the issue. My experience, with early intervention, has taught that the incidence of chronic arteriosclerotic nephritis in later years is very markedly reduced, by shortening the duration of toxemic states. That so-called renal cases are not nephritic in the early stages of the disease is manifest. But that they are prone to become nephritic if the vitiated metabolism persists is parallel with similar conditions in thyroid and pancreatic and other endocrine dyscrasias.

Study of placental disease has taught me that a large percentage of children enter the first stage of labor handicapped by placental disease, and these may readily lose out in any prolongation or major effort in the second stage, at which time placental circulation is

greatly impeded by the slowly diminishing placental site. The wonder also is that clinical placental hemorrhage is so common when placental hemorrhages are so very frequent. There is still much that requires elucidation.

ABSTRACT OF DISCUSSION

DR. J. C. JANNEY, Boston. The most notable advance in the study of toxemia is with regard to placental disorders. Dr. Goodall speaks of the frequency of anemia in pregnancy. Davis and Walker have reported similar observations. Although this report dealt with nontoxic patients, no one who is familiar with the importance allotted to anoxemia in the production of toxemia can fail to see that fighting the anemia and preserving the oxygen carrying power of the blood is one of the important ways of preventing or minimizing local damage in organs with low functional reserve. As to the etiology of toxemia, I should like to accept the original suggestion of Hofbauer that the cause is hypersecretion of the posterior pituitary, and the work of Anselmino and Hoffman demonstrating the presence of pressor and antidiuretic substances in the blood of patients with severe grades of the disease. My associates and I have been trying to repeat the experiments but have reached no conclusion. The classification of toxemia as taught at present is unnecessarily complicated but I cannot simplify it to one group. I should make preeclampsia and eclampsia a single group as Dr. Goodall does and I agree with him that the different renal, hepatic, convulsive and gastro intestinal manifestations are not due to differing primary or intermediate causes but rather to individual system instabilities in different patients. Pernicious vomiting and acute yellow atrophy of the liver may be shown to be manifestations of the toxemia of pregnancy. Low reserve kidney and chronic nephritis form what might be termed the decompensated kidney. It makes no difference from the point of view of the present pregnancy whether the kidney has been damaged by previous illness or is congenitally inferior. The essential feature is decompensation from overload. From the point of view of prognosis, however, the two may behave very differently. Long-term prognosis has received insufficient stress. The old idea that eclampsia conferred an immunity in subsequent pregnancies has been forced into the discard by the work of Peckham and others, who have shown that a very high proportion of such cases have been left with chronic nephritis. Heretofore it has been the accepted practice, except in the convulsive type of toxemia, to continue the pregnancy as long as it was safe. This subjected the liver, kidneys and other important organs to the greatest amount of damage consistent with life whereas if the patient had had a convulsive type of the disease and recovered she might likely have had less permanent damage to these organs because the pregnancy was promptly terminated and the toxemia thereby halted.

DR. KATHERINE KUDER, New York. The lack at the present time of a uniform method of classifying the various types of toxemia of pregnancy is a drawback in any attempt to correlate the ultimate observations of different investigators. In the obstetric division of the Woman's Clinic of the New York Hospital the value of certain kidney function tests, especially the urea clearance test, is emphasized. Kidney function tests assist in the differential diagnosis between chronic nephritis and preeclampsia (eclampsia) and the group of toxemia in which the kidneys are not injured by pregnancy. In chronic nephritis the tests show decreased function. In a woman suffering from a definite and proved chronic nephritis, we advocate termination of the pregnancy and prevention of any further pregnancies. It is our practice to study carefully the blood chemistry of all patients suffering from a toxemia of pregnancy. The results show very slight variation from the normal in cases of chronic nephritis complicated by pregnancy except when the nephritis is so severe as to be accompanied by nitrogenous retention. However, in preeclampsia, the blood chemistry is of value as it shows a steadily increasing uric acid content and often a lowered carbon dioxide combining power. It is contrary to our teaching to classify toxemia on the occurrence of clinical manifestations for totally different pathologic conditions may

be accompanied by the same symptoms. In their follow-up study of a large series of patients with chronic nephritis complicated by pregnancy, Stander and Peckham have shown that 40 per cent of these women died within ten years after the diagnosis was definitely established. This shows the grave prognosis of the condition and the importance of recognizing early in pregnancy an underlying nephritis so that the patient may be given the proper treatment. Dr Stander regards nephritis complicated by pregnancy as a distinct and separate entity or disease process from eclampsia and preeclampsia. Blood studies, the subsequent history of the patient and the kidney function tests all support this contention. He has seen no patient in whom the diagnosis of nephritis complicated by pregnancy was established beyond doubt by chemical and laboratory observations, including repeated kidney function tests, who was cured of the nephritis during, after or by a pregnancy.

BLADDER ABNORMALITIES DUE TO INJURY OF MOTOR PATHWAYS IN THE NERVOUS SYSTEM

LLOYD G. LEWIS, MD

ORTHELLO R. LANGWORTHY, MD

AND

JOHN E. DEES, MD

BALTIMORE

It is important to recognize and catalogue the changes in micturition that may be produced by neurologic lesions. It is necessary to deal not only with trunks of sympathetic and parasympathetic fibers that supply the bladder but also with reflex arcs in the brain and cord extending as high as the cerebral cortex. Lesions may occur on the sensory or on the motor side of the reflex arc. The loss of sensory impulses may give rise to variable symptoms, depending on the level in the nervous system at which the fibers are interrupted and on the sensory pathways that are damaged. Tabes dorsalis furnishes a good example of an interruption of the sensory fibers in the posterior roots producing vesical symptoms. In this paper we discuss lesions of the motor pathways from the brain that influence the bladder. Of these long motor pathways two are known, one arising in the cerebral motor cortex and one in the midbrain.¹

The present study is based on physiologic experiments reported some years ago by one of us.² Later we discussed at some length the neurophysiology of the bladder in connection with lesions of the spinal cord.³ The reader is referred to these earlier reports for a consideration of fundamental theories concerning the function of the smooth muscle of the bladder wall in relation to its nerve supply.

METHODS

Under the heading of methods we consider the general principles of a successful apparatus. We feel that manometers utilizing water instead of mercury should be used for several reasons. The waves of contraction

This study of the control of the bladder by the central nervous system was supported by a grant from the National Research Council.

Read before the Section on Urology at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1935.

during filling will be found of great importance in reaching conclusions concerning detrusor activity. These waves are greatly damped or even lost by the inertia of mercury. An air-water system will at once record any rise or fall in intravesical pressure.

Another advantage of the water manometer is the inexpensiveness of the material required. With a few lengths of glass and rubber tubing it is possible to construct an apparatus that is adequate in every respect and that can be sterilized.

The instrument is shown in figure 1. A soft rubber catheter was inserted through the urethra into the bladder. This was connected by a T tube with a source of sterile fluid and with the manometer. We not only recorded the intravesical pressure during filling by measuring the height of fluid in the glass tube but also made records on a kymograph. We could not have reached certain conclusions concerning waves of vesical pressure unless these graphs had been available.

Respiratory waves may be differentiated easily from the slow waves of contraction of the bladder muscle. We noted any changes in pressure due to coughing, straining or movements on the part of the patient. The patient should lie flat on the back and remain as quiet as possible during the readings. Toward the end of filling, in certain cases in which it was of interest, the patient was asked to attempt micturition, and the subsequent rise of pressure was recorded. The type of graphic record that is obtained varies with the method of bladder filling. It is most satisfactory to introduce the fluid in equal portions (25 or 50 cc at one time) and record the behavior of the bladder in the intervals. By this method

Fig. 1—Apparatus

it is possible to see the reaction of the muscle to sudden stretch and to measure the time required for the pressure to reach a resting level in accommodation to the new volume. The activity of the stretch reflex, which is of fundamental importance in the activity of the muscle, is tested in this way.

In this paper only the activity of the detrusor muscle is considered, and the pressure at which the sphincters opened. It is clear that the detrusor muscle normally is adapted for the storing of urine and that its contraction initiates micturition.

There is a certain distortion of the graphic record, owing to the stretch coefficient of the rubber diaphragm in the tambour. The rubber stretches markedly with slight increase in pressure, but the stretch is proportionately less marked as the pressure rises. Therefore slight changes when the pressure is low are magnified out of proportion to the changes at higher pressures.

CYSTOMETRIC READING MADE FROM A PATIENT WITH NORMAL BLADDER INNERVATION

The cystometric reading that is discussed as normal was made on a patient with an obstructive lesion at the vesical orifice and with a slightly contracted bladder.

The graph is shown in figure 2. An ideal adjustment of the catheter was made while the bladder was empty, so that respiratory waves were recorded. The pressure in the empty bladder was between 1 and 2 cm of water. Fluid was introduced in equal amounts of 50 cc until filling was complete. The intravesical pressure fell quickly to a resting level. Following the introduction of the first quantity of fluid the pressure was from 3 to 4 cm and was 8 cm only after 250 cc had been injected. When the bladder contained 150 cc and again at 200 cc there were irregularities in the graph resulting from movement on the part of the patient with 200 cc in the bladder there was the first feeling of distention. As filling progressed the bladder accommodated an increased volume less quickly. After 300 cc had entered the bladder the pressure fell slowly. There were a number of small waves of contraction, the pressure rose rapidly to 70 cm, and fluid escaped around the catheter. We felt that this was a normal record except that the total volume was somewhat below the average. A series of readings on normal individuals with bladder capacity of from 500 to 550 cc has been made.

TYPES OF LESIONS OF THE NERVOUS SYSTEM

In figure 3 we have endeavored to give a suggestion of the position of the lesions discussed in this paper. The bladder is bilaterally represented in the cerebral motor cortex. Patients were chosen with bilateral cerebral accidents that injured the motor pathways on both sides, the lesion would correspond to an injury at a level marked 1. Also patients with unilateral lesions were studied, the injury would correspond to the section of one pathway at 2. The changes in the extremities of the latter patients were manifested as a hemiplegia. The other motor pathway arises from cells in the region of the midbrain, they apparently have to do with the control of tone in the smooth muscle of the bladder wall. The manner in which the tracts from these two regions make connections in the

changes of the functioning of the bladder occur. The possible position of the lesion is indicated as 1 in figure 3. Under these conditions the bladder empties frequently and precipitously when small amounts of urine collect.

Usually the patient has little voluntary control and is constantly incontinent. If the sensory fibers to the cortex are uninjured, the patient may be aware of the imminence of micturition.

CASE 1—A white man, aged 64, was diagnosed as having syphilis, bilateral hemiplegia, pseudobulbar palsy and bladder and bowel incontinence of five months duration.

The record of the cystometric reading is shown in figure 4. The resting pressure in the bladder was 2 cm of water. After 25 cc. of fluid had been introduced the pressure gradually fell to a resting level of 6.5 cm. Respiratory waves were recorded. Then the volume of the bladder was increased to a total of 50 cc. A cough occurred which caused a sudden change of pressure. There was delayed accommodation. Then a wave of contraction occurred, followed by a fall of pressure and a sudden, precipitous rise to 96 cm. The bladder emptied completely around the catheter.

Fig 3—Position of lesions.

The average normal capacity of the human bladder is about 500 cc. In this patient the bladder contracted forcibly and emptied with a volume of 50 cc.

CASE 2—A white man, aged 51, was admitted to the hospital in 1935. The diagnosis was bilateral hemiplegia, pseudobulbar palsy, and bladder and bowel incontinence.

Figure 5 shows the behavior of the bladder as twelve equal amounts of fluid of 25 cc. were introduced, a total amount of 300 cc. of fluid was used. The rises in pressure due to the addition of fluid are marked with white dots in order to increase the ease of reading the graph. Immediately after 75, 125, 175, 225 and 300 cc were introduced, a contraction of the bladder musculature occurred. Some fluid escaped around the catheter at each rise of pressure, although the bladder did not empty completely. These contractions were of greatest force early in the process of filling, and they decreased in amplitude as a greater volume was attained.

The rises show that the muscle was hyperirritable to stretch stimuli. Contractions occurred only as every other 25 cc. of fluid was added.

UNILATERAL LESIONS OF THE CEREBRAL MOTOR CORTEX OR OF THE INTERNAL CAPSULE

In the basic work dealing with acute experiments with animals it was found that removal of one cerebral motor cortex caused a marked decrease in bladder volume.² Removal of both cerebral cortices produced a further decrease in bladder volume, the bladder then behaved after the manner described in the preceding section. Later the cerebral motor cortices were stimulated and the behavior of the bladder was noted.¹ This stimulation produced a fall in intravesical pressure followed by a sharp rise initiating micturition, if stimu-

Fig 2—Normal cystometric reading

lous to influence the preganglionic autonomic cells is little understood. The final group of abnormalities that we shall discuss have to do with lesions of the motor tracts in the spinal cord. Here the two motor tracts lie close together in the lateral columns of the cord.

BILATERAL LESIONS OF THE CEREBRAL MOTOR CORTEX OR OF THE INTERNAL CAPSULE

After bilateral lesions of the cerebral motor cortex or of the internal capsule, injuring the fibers running from the cortex to the spinal cord, characteristic

lation was continued. We found that responses could be obtained more easily from one cortex than the other, and that usually the left was the more responsive. It was suggested that one cortex was dominant in bladder control.

We have studied the behavior of the bladder in seventeen persons with unilateral lesions of the cerebral motor cortex or internal capsule, with the typical changes in the extremities characteristic of hemiplegia.

Fig. 4—Cystometric reading in case 1

one hemisphere is dominant in bladder control, and that this dominance is on the left side in right handed persons.

CASE 3—A Negro, aged 50, in August 1929 developed typical left hemiplegia with characteristic posture of the arm and leg.

A graphic record of the bladder function is shown in figure 6. Six equal quantities of fluid of 50 cc. were introduced into the bladder, which emptied on 300 cc. of fluid. The initial pressure in the empty bladder was 6 cm. of water, and the pressure remained below the level of 14 cm. of water until the bladder held 300 cc. Even with the viscous empty, and during the entire process of filling, small rhythmic contraction waves

Fig. 5—Behavior of bladder in case 2

occurred. These have never been observed in the normal person. After the introduction of a quantity of fluid the pressure was slow in reaching a resting level, this became more marked as filling progressed. The rise of pressure at the end was definitely related to the introduction of fluid. Waves developed which rapidly fused into a tonic contraction, emptying the bladder. This is a typical illustration of the type of graph

obtained from patients with a left hemiplegia. The total volume, however, was comparatively small.

CASE 4—A Negro, aged 42, suddenly developed right hemiplegia with aphasia in October 1927.

The record of vesical function in this patient is shown in figure 7. Fluid was added in four equal quantities of 50 cc. Even with the bladder empty, contraction waves were present. They occurred throughout the course of filling, and the fall to a resting pressure was delayed after fluid was introduced. The pressure rose rapidly on 200 cc. of fluid, and the bladder emptied.

CASE 5—A Negro, aged 43, lost the use of his right arm and leg in June 1934. A marked aphasia developed at the same time.

Study of the bladder revealed marked motor abnormalities which are shown in figure 8. These have to do particularly with increased response to stretch stimuli. The pressure in the empty bladder was from 3 to 4 cm. of water, respiratory waves were recorded. After the first 50 cc. was introduced, the pressure fell slowly to a resting level of 6 cm. and there were small, irregular waves of contraction. Immediately following the introduction of each of the next three 50 cc. of water, the pressure rose to 76 cm. and sustained this level for some time. Irregularities of pressure were seen throughout the graph. Some urine was expelled with the strong contractions, but the bladder did not empty completely. When the bladder contained 200 cc. it contracted strongly not only once but a second time, and the experiment was terminated.

Fig. 6—Function of bladder in case 3

BEHAVIOR OF THE BLADDER AFTER INJURY OF THE MOTOR PATHWAYS IN THE SPINAL CORD

No cases of bilateral injury of the pathways arising in the midbrain that influence the activity of the bladder musculature have yet been recognized in isolated form. The pathway from the midbrain must be close to the corticospinal pathway in the lateral columns of the cord, and the two may be injured together. We shall present examples of spinal cord injury which produce abnormalities corresponding to those described in the preceding section. Later other examples will be given in which we feel that both the corticospinal tracts and the pathways from the midbrain had been injured bilaterally.

CASE 6—A Negro, aged 43, developed paraplegia in extension three years ago. This is a case of disseminated sclerosis. He never complained of any urinary symptoms. He stated that he micturated two or three times a day and twice at night.

Examination of the bladder function showed marked hyperactivity of the stretch reflex, as shown in figure 9. Fluid was introduced into the bladder in four equal quantities of 50 cc. The graph of the empty bladder recorded small waves of contraction. After each quantity of fluid was introduced, the pressure rose rapidly to over 65 cm. of water, and almost complete evacuation occurred with each rise. This is an excellent example of abnormality due to bilateral involvement of the corticospinal fibers to the bladder.

Another example of similar nature is given in which the bladder did not respond to each addition of fluid, and contractions due to more complicated causes were observed

CASE 7—A white woman, aged 39, suffered from disseminated sclerosis. In 1924 her legs became weak and a year later she noticed decreased visual acuity. In 1925 she first developed frequency and urgency of micturition, and this has been one of the most unpleasant symptoms of the disease as she had to empty the bladder almost hourly during the day and night. Report of the neurologic examination will be omitted except for the difficulties in the legs. The patient walked unsteadily on a broad base. There was outspoken ataxia of both legs. The deep reflexes were hyperactive in the legs, and there was a bilateral Babinski reflex. The blood and spinal fluid Wassermann reaction was negative.

The bladder record is shown in figure 10. Small contraction waves were seen with the bladder empty and throughout filling. The pressure with the viscus empty was 5 cm of water. The pressure fell to a level of 6 cm after the first 25 cc of fluid had entered the bladder. Then a sharp rise occurred to a pressure of 68 cm without the escape of fluid. We believe that this rise was dependent on psychic stimulation. The door was suddenly opened and some one spoke in a loud voice. We have shown in another place that the corticospinal responses

are sometimes not entirely lost in patients with the bladder symptoms characteristic of disseminated sclerosis, and that the intravesical pressure may be either raised or lowered by psychic stimuli.³ The pressure remained low after the next two quantities of 25 cc were introduced, but when the volume was made 100 cc it rose to 70 cm and the patient voided 75 cc, leaving a residual amount of 25 cc. The pressure fell to a resting level. Then no rise in pressure occurred until 75 cc had entered

Fig 7—Vesical function in case 4

tered the bladder, making a total of 100 cc. Again the pressure rose to the former high level and 75 cc. was voided. It may be assumed in this case that the stretch reflex became active on a volume of 100 cc.

In the next two patients there was a different type of contraction wave with filling.

CASE 8—A Negro, aged 39 developed spastic paraplegia in 1925 due to syphilis. The patient complained of incontinence. This consisted of extreme urgency so that it was impossible to hold any quantity of urine, and dribbling occurred.

The bladder study is graphically represented in figure 11. Rhythmic waves were present even with the bladder empty. The introduction of 50 cc. of fluid was followed immediately by two large waves. The pressure then fell to a high resting level, and small contractions occurred at intervals. The patient was conscious of fullness during the large waves but was comfortable after they subsided. Increasing the volume of the bladder to 100 cc. is recorded on the graph by the second white dot. Then repeated large contraction waves occurred and the pressure never fell to a resting level. By engaging the patient in conversation we postponed the onset of the seventh wave. There was discomfort when the pressure was high. The waves continued with 150 cc. in the bladder, with moderate to severe discomfort. Some fluid escaped at the peak of the waves. With 200 cc. of fluid in the bladder the patient experienced severe pain. He could not voluntarily raise the pressure to a high level. The experiment was terminated at this point.

This record differs from the others in that the bladder was not only hyperirritable to stretch but rhythmic waves of contraction occurred continuously. These waves were relatively inefficient in discharging urine. There was little sensory involvement in the legs. We believe that in this case both of the motor pathways from the brain were interrupted bilaterally.

Fig 8—Motor abnormalities shown in case 5

CASE 9—A white man, aged 54, first noticed some weakness of both legs in 1932. Two years earlier he had developed frequency of micturition. In 1932 he suddenly became unable to void and since that time has used a catheter daily. There was slight spasticity of the legs. His gait was both spastic and ataxic, and the Romberg test was positive. Pain responses were poor in the ankles. The vibratory sense and sense of passive movement were unimpaired. There was a bilateral Babinski reflex and bilateral ankle clonus. The Wassermann test was negative in the blood and spinal fluid.

Figure 12 shows the filling record in this case. The pressure remained low until the volume was 150 cc. Then contraction waves appeared not only related to the introduction of fluid but also occurring rhythmically. They became more marked after the capacity reached 250 cc. The patient was very uncomfortable with 400 cc. in the bladder, and the waves were of great height. He was then asked to attempt to micturate and raised the pressure to 115 cm, fluid escaped from the bladder. The frequent waves during filling with no sustained rises of pressure suggest an injury of both motor pathways from the brain.

COMMENT

The graphic method of recording vesical activity through an air-water system gives a clear picture of contraction waves during filling. These waves are not present in normal individuals, and their study is of

Fig 9—Marked hyperactivity of stretch reflex shown in case 6

importance in estimating the degree of loss of function. Normal micturition depends on a steady rise of bladder pressure of sufficient strength and duration to empty the viscus completely. When waves occur rhythmically and frequently, they do not have the strength or duration for efficient emptying. There may be some escape

of fluid at the height of the waves. As the neurologic control of the bladder is progressively lost, the waves become more frequent but their force and duration become smaller.

The cases reported are typical examples of a large group of patients who were studied. The first group recorded bladder activity after removal of all motor

Fig 10—Bladder record in case 7

stimuli from the cerebral cortices. Just as in striated muscle so in the case of the smooth muscle of the bladder the cerebral cortex controls activity. It enables the bladder to hold large amounts of fluid at a relatively low pressure below the level of discomfort. After the removal of this influence the bladder capacity becomes smaller, and there is frequency of micturition.

The effect of loss of this cortical control can best be expressed in another way as a hyperirritability of the stretch reflex. Again an analogy with striated muscle can be used. The tone and to a certain extent the contraction of striated muscle is dependent on afferent stimuli, arising in the muscle itself. This is exemplified by the knee jerk. The sudden stretch applied to the tendon of the quadratus femoris stimulates the sensory endings in the muscle and produces a reflex contraction. These stretch reflexes are normally controlled by the cerebral motor cortex, and the deep reflexes become hyperactive after injury of the corticospinal fibers.

Denny-Brown and Robertson⁴ showed clearly that the smooth muscle of the bladder also responded to the stretch, and its activity was built up primarily on the basis of the stretch reflex. It is only necessary to

Fig 11—Bladder study in case 8

examine the graphs in this paper to realize that the stretch reflex in the smooth muscle of the bladder is hyperactive after loss of cortical stimuli. Immediately after the introduction of fluid a strong contraction of

the muscle occurs, which is dependent on the sudden stretch produced by the fluid. This rise does not occur in a normal person, at least till the end of filling.

After injury of the corticospinal fibers, even on one side, similar increase in the stretch reflex is often seen. This is particularly true with lesions of the left side of the brain producing a right hemiplegia. It may be concluded that one hemisphere is normally dominant in the control of vesical activity.

The rapid and forceful rise of pressure dependent on the hyperactivity of the stretch reflex demands an immediate emptying of the bladder and gives rise to the complaint of urgency. As the normal cortical control is no longer present, these patients are unable to overcome the waves of contraction and cannot postpone micturition by a conscious effort. If the force of the waves is less marked, the urgency is less severe.

The frequency of micturition with the expulsion of a small volume of urine is dependent to a great extent on this hyperactivity of the stretch reflex. It is largely a physiologic abnormality and is not dependent on fundamental anatomic changes making the bladder small. This is evident from the fact that the patients often notice frequency only on some days, while on other days the bladder will hold a normal quantity. Excitement may at times give rise to frequency in the normal person.

Fig 12—Filling record in case 9

There is, however, another factor that undoubtedly contributes to the small quantity of urine which these abnormal bladders hold. After section of the corticospinal fibers there is increased tone of the striated muscle. This again is dependent on the hyperactivity of the stretch reflex. The increase in tone is more difficult to demonstrate in the case of the bladder. If the pressure falls to a resting level, it seems little higher than the resting level in a normal bladder. In some cases, however, the pressure during filling was high even at a resting level. It is probable that the small volume is dependent on the increased tone of the smooth muscle of the bladder wall decreasing the lumen of the viscus.

In all these patients with bilateral or even unilateral lesions of the corticospinal tracts the external sphincter showed increased tone. Denny-Brown and Robertson⁴ have suggested that this is dependent on an increased tone of the striated muscle entering into the composition of the external sphincter. This is not an all inclusive explanation, as the external sphincter has marked tone in patients with tabes. In these patients the striated muscle shows loss of tone.

When the interior of the hyperirritable bladder is examined with a cystoscope, coarse trabeculations of the detrusor are seen and the trigon shows hypertrophy. Whether this is due to actual increase in muscle volume or to thickening of the wall dependent on its small size it is difficult to say.

⁴ Denny Brown D. E. and Robertson E. G. On the Physiology of Micturition. *Brain* 56: 149 (July) 1933, The State of the Bladder and Its Sphincters in Complete Transverse Lesions of the Spinal Cord and Cauda Equina, *ibid* 56: 397 (Dec) 1933.

It is thought that the pathway from the midbrain influencing the bladder has to do with the control of tone in the wall. This mechanism is released from cortical influence and permitted to overact after bilateral injury of the corticospinal path. We have not recognized a case in which this mechanism was injured bilaterally without involvement of the corticospinal fibers. Theoretically this would produce an enlargement of the bladder with difficulty in emptying.

If these midbrain pathways are injured in the cord together with the adjacent corticospinal fibers, one would expect that bladder function would be less efficient. The waves of contraction, while occurring more often, are not of sufficient strength or duration to permit efficient emptying of the bladder. Fluid escapes from the urethra at the height of the waves, and the patient has little if any voluntary control, because of interruption of the corticospinal fibers. We have presented graphic records from two cases that fall into this group.

Rose⁵ has done a great service in popularizing cystometry among urologists. Recent workers⁶ have spoken of hypotonic and hypertonic bladders. This is perhaps a convenient classification, but it does not explain all possibilities of bladder abnormality. A hypotonic bladder may be one produced by injury of the posterior spinal roots in *tabes dorsalis*. Here, owing to overdistention and loss of tone, the bladder is able to accommodate large amounts of fluid at a relatively low pressure. We have been able to produce this condition experimentally and follow its evolution.⁷ The bladder would also be hypotonic immediately after a severe injury to the spinal cord, as the result of the so-called shock resulting from sudden interruption of pathways in the cord. Later with the development of reflex micturition it would be considered hypertonic. It has been shown that the bladder of small capacity after bilateral pyramidal tract injury is probably a hypertonic bladder in the true sense of the word. Here the resting pressure in the bladder is usually greater than normal. Of more importance than the resting pressure is the powerful, sudden contraction of the bladder that follows stretching of the muscle.

SUMMARY

By means of an air-water manometer and recording tambour we have made graphic records of the behavior of the detrusor muscle during bladder filling. The bladder muscle characteristically responds to stretch stimuli, and important information can be obtained by observing and recording waves of bladder contraction. Patients were studied who suffered either bilateral or unilateral pyramidal tract injuries or had lesions of motor tracts in the spinal cord. With release from cortical control, the stretch reflex is hyperactive. The bladder empties precipitously with a small volume of fluid. When the motor pathways from the midbrain are injured bilaterally along with the corticospinal tracts, the waves of bladder contraction are frequent but of small amplitude. They are ineffective in emptying the bladder. A study of contraction waves of the muscle during filling is of aid in forming an opinion of the efficiency of a bladder with damaged innervation.

ABSTRACT OF DISCUSSION

DR. JOHN DUFF, New York. I congratulate the authors on their skilful use of cystometry in arriving at conclusions as to basic neurologic control of the normal and abnormal function of the bladder. It would appear that cystometry is not used with sufficient frequency in urologic clinics as a means of differential diagnosis and research. The authors have drawn interesting parallelisms between spastic voluntary musculature and what one might term a spastic urinary bladder, both resulting from interruption of cortical control. The commonly known efferent nerve fibers to the urinary bladder are the autonomic, sympathetic and parasympathetic fibers. The well known fibers of the cerebrospinal system are the somatic fibers assembled in the pyramidal tracts. The authors have shown that the central somatic system seems to establish connection not only with the lower voluntary motor neurons but also with the peripheral autonomic system of the bladder. I believe it true that pathologic lesions interrupting the pyramidal tracts frequently involve other related structures of the central nervous system. It is possible that the bladder disturbance in involvement of the pyramidal tract could be due to damage to adjacent visceral pathways. One might suppose that such visceral pathways could arise subcortically. The further postulation as to tonic control of the bladder from the midbrain centers explains satisfactorily the diminution of bladder tonus in lesions of the cord, which are so widespread as to intercept pathways both from the cortex and midbrain. The idea of central antagonistic pathways to the urinary bladder, inhibitory from the cerebral cortex and tonic from the midbrain, is most interesting and significant. It should help further to clarify problems of bladder dysfunction in lesions of the central nervous system. The work of Barrington, Dennig, Muller, Learmonth, Denny-Brown and Robertson bears out many of the significant points of this paper.

DR. MAURICE MUSCHAT, Philadelphia. Studies of relationship of the nervous system to the urinary bladder are now abundant, but they always remained a laboratory procedure and of merely academic interest. It was Dr. Rose's great contribution to apply this work at the bedside and thus aid the clinician in diagnosing a neurogenic bladder. With the simplification of the cystometer, such bedside studies have become popular. By using a water manometer, one is able to note the slightest fluctuations in the tonus of the detrusor and to evaluate the variations noted. For the ordinary clinical work of the urologist, a water manometer is somewhat unhandy and unnecessary. I feel that a practicing urologist should not as yet enter into discussions of the complicated neurologic problems. This is still the work of the neurologist. By means of the cystometer one obtains three factors: the desire to void, the pressure curve and the maximal voluntary pressure. With a normal bladder the desire is to void from 150 to 250 cc. of urine, the pressure curve is gradually ascending and the maximal pressure is from 40 to 60 mm. In the hypertonic bladder the factors are altered. The desire to void is less than 150 cc. of urine, the curve is very acute, and the maximal voluntary pressure is more than 60 mm. In the hypotonic bladder it is just the opposite. The desire is to void more than 250 cc. of urine, the curve is flat and the maximal voluntary pressure is less than 40 mm. Alteration of at least two factors is characteristic for a neurogenic bladder. The authors did not stress strongly enough the fact of finding marked abnormalities of the bladder in cases in which there were no urinary complaints. This possibility must be borne in mind and bladder dysfunction as evidenced by the cystometer looked for in every case in which a central or a spinal lesion is suspected. A positive finding becomes of inestimable value in the diagnosis of such cases.

DR. IRVING SIMONS, New York. In my clinic we have been interested in a study of the function of the bladder in various diseases including diseases of the central and autonomic nervous systems. Physiologically the bladder should be considered as made up of two organs: (1) a detrusor or bladder proper, the contraction of which is governed by the parasympathetic nerves, and (2) an inner lock or internal involuntary sphincter, the tonus of which is governed by the sympathetic nerves. Beyond this is a second or external lock composed of the external sphincter, assisted by the bulbocavernosus and other perineal muscles. Cystometry records data merely of the action of the

detrusor, and this gives an idea only of the force but does not take into consideration the resistance that this force has to overcome. I have devised an instrument which may be termed a sphincterometer, by means of which we have been able to measure the tonus of the internal as well as the external sphincter. Clinical reports on this instrument will appear in the near future. In order to use this sphincterometer, it was necessary to construct an instrument, the portable microcystometer, which will accurately inject any amount of fluid at any rate and pressure. It will measure the tension or pressure on the bag developed by such an injection, or, if a plain catheter is used, it will measure the pressure exerted on the fluid injected into a muscular organ, the bladder. This is recorded with the greatest accuracy, as it is equipped with a reservoir type manometer of U S Bureau of Standards specifications, with accurately calibrated scale. The instrument is equipped with a pressure tube or intermediary, the fluid and air capacity of which has been diminished to the lowest point possible for clinical use, by which reduction the errors of pressure have been minimized and the load of fluid to be lifted by the bladder has been diminished to a point that will ensure the greatest accuracy possible. In making cystometric observations we have used the fractional injection method advised by Rose, using as the unit injections of 50 cc., injecting these increments without undue force or haste, and recording the pressure of each increment immediately so as not to allow the detrusor to relax after its reception of the increment. It is of paramount importance that the sensory filling points, of desire to void of pain and of severe pain, be accurately elicited by questioning the patient as without them curves of pseudoneurogenic or nonneurogenic hypertonia and hypotonia cannot be accurately differentiated from true neurogenic hypertonia and hypotonia. We feel that the accuracy of this cystometer has allowed us to separate four groups from the normal instead of the two described previously. In our work we have substituted for the graphs of Rose a numerical record similar to that of recording a gold chloride report.

DR. WILLIAM BISHOP, New York. In a series of cases studied by Dr Simons and myself by the fractional method with the microcystometer we were able to define four distinct groups that varied from the normal. Particular attention was paid in eliciting the sensory points: desire to void, pain and severe pain. We charted our results without graphs, separating the pressure obtained at each increment of 50 cc. by a comma and each 250 cc. by a semicolon. In five separate series of cases the average results obtained were as follows: 1 True neurogenic hypertonia was found in spastic paraplegia and combined sclerosis. These patients have short records averaging four increments. All the sensory points are moved to the left. 2 In nonneurogenic hypertonia consisting of cases of increased intracystic pressure in which no essential neuropathologic condition could be found, pressure develops rapidly, usually after 200 cc. of fluid has been introduced. Their sensory points are normally situated and the average length of their record is twelve increments. 3 Normal cases show gradual rise in intracystic pressure with a record of twelve increments. The sensory points were found in the fourth, eighth and tenth increments. 4 In nonneurogenic hypotonia neuropathologic changes were excluded clinically and serologically. Cystometrically they masqueraded as true neurogenic hypotonia because of their low tension and the length of their record. Their sensory points, normally or nearly normally placed, distinguish them from the true neurogenic hypotonia. 5 True neurogenic hypotonia was found in a series of cases of tabes and tabes with dementia paralytica. They have very long records with an average of twenty increments. All sensory points are moved to the right.

DR. LLOYD G. LEWIS, Baltimore. I wish to emphasize the value of obtaining graphic records of cystometric studies. The cystometer should be sensitive enough to record accurately every change in vesical pressure, but the graphic record is of great importance for a comparison of curves and for reaching conclusions. With our simple apparatus we have been able to record variations in bladder pressure due to respiration, variations of tonicity of bladder musculature and fluctuations due

to hyperactive stretch reflex and straining pressures. It is obvious that only detrusor pressure can be determined by this instrument. Lesions of the motor pathways of the bladder in the brain and spinal cord may be studied satisfactorily by this type of apparatus. Dr Simons' instrument may be well adapted to study of the vesical sphincters.

ARTIFICIAL FEVER THERAPY OF SYPHILIS

WALTER M. SIMPSON, M.D.
DAYTON, OHIO

Artificial fever therapy now occupies a commanding position in the management of neurosyphilis. During the eighteen years that has elapsed since the monumental researches of Wagner-Jauregg¹ in the malaria therapy of dementia paralytica, it has become more and more apparent that simple fever production is the one factor common to the great variety of infectious, chemical and physical agencies that have been employed as substitutes for malaria therapy. This observation has led to a diligent search for physical methods which would overcome the inconstancy and hazards that attend the production of artificial fever by infectious agents, such as malaria, rat-bite fever or relapsing fever. Experiments in fever production have been conducted with many physical modalities (hot baths, hot air, diathermy, radiothermy and electric blankets). While comparable clinical results may be obtained with any of these methods, it has been recognized that many possess inherent hazards.

In a previous report,² the early results obtained in the pyretotherapy of neurosyphilis were described. Ultra-high frequency electric currents (10,000,000 cycles, 30-meter waves) applied by means of condenser discharges of a modified short wave radio transmitter, developed by Whitney,³ Page⁴ and De Walt,⁵ were applied in an air-conditioned cabinet, developed with the collaboration of Mr. Charles F. Kettering and Mr. Edwin C. Sittler of the Research Laboratories of the General Motors Corporation. The purpose of the air-conditioned cabinet was to dissipate sweat as it collected on the skin surface and thus to prevent arcing and burning of the skin as the result of concentration of the short radio waves in the drops of sweat.

Soon after this report was made, an accidental observation caused us greatly to alter the method of producing and maintaining artificial fever. While subjecting a child with congenital syphilis to artificial fever therapy by the combined radiotherm and air-conditioned

cabinet method, the nurse-technician failed to turn on the switches controlling the output of the high frequency currents. The rectal temperature reached the desired level of 106 F in the usual time (fifty minutes). It was then discovered that the high frequency currents had not been utilized for fever induction. By adjusting the air temperature-humidity factors in the air-conditioned cabinet the temperature was maintained at this level for the usual five hour period.

This fortunate occurrence led us to develop a much simpler, safer, less costly and more easily controllable air-conditioned apparatus (Kettering hypertherm) for fever production and maintenance (fig 1). High frequency currents are no longer employed. Deep tissue temperature studies made with thermocouples revealed no essential difference in deep heating effect when fever was produced by either high frequency currents (diathermy or radiothermy) or by conditioned air alone.

In its present state the Kettering hypertherm⁶ consists of an insulated cabinet in which the nude patient lies, with his head extending outside the cabinet. Sponge-rubber insulation is utilized in the neck region to permit the patient to shift his position. The patient lies on an air mattress, supported by a boxlike bed which is rolled in and out at will. In the rear of the cabinet is a small insulated fire-proof compartment in which the air-conditioning apparatus is housed. The dry bulb air temperature is controlled by a thermostat. The wet bulb temperature, which governs the percentage of relative humidity, is controlled by a humidistat or by a wet bulb thermostat. The air velocity within the cabinet is controlled by blowers of fixed speed. Dry bulb and wet bulb temperatures within the cabinet are indicated on large dials, equipped with warning pilot lights, on the top of the front end of the cabinet, where they may be constantly observed by the nurse-technician. The temperature-humidity factors may be controlled by the turning of a single knob. The average set of air conditions to which the patient's body is subjected is as follows: dry bulb air temperature of from 130 to 150 F, relative humidity of from 35 to 50 per cent, and air velocity of 425 cubic feet per minute. The elevation of the rectal temperature to 105 F is ordinarily accomplished in from forty minutes to one hour. The air is constantly conditioned by continuous passage through the air-conditioning compartment. The safety and comfort of the patient are greatly enhanced by the accurate control of the relative humidity.

The mechanism of fever induction with the Kettering hypertherm depends primarily on heat transfer by conduction from the circulating heated air. This factor combined with prevention of the normal rate of heat loss from the body by radiation and evaporation, is responsible for the elevation of the body temperature and its maintenance at any desired level.

The simplification of the apparatus, the removal of hazards inherent in certain other physical modalities, and the supplying of large quantities (2 to 4 liters) of sodium chloride solution (0.6 per cent) by mouth

6 Fifty five of these units have been lent to twenty medical research centers strictly for investigative purposes. The physicians and nurses charged with this undertaking received special training in the Department of Fever Therapy Research at the Miami Valley Hospital before the apparatus was released. A simpler, smaller and less costly apparatus is now being developed. It is probable that this apparatus will ultimately be available to certain qualified institutions. Adequate preliminary training of physician and nurse personnel is an essential requirement for this type of work. Artificial fever therapy should be restricted to qualified institutions. Otherwise this method of therapy is almost certainly doomed to a period of discredit not unlike that which followed the introduction of roentgen rays. The production of artificial fever at a high level is not adaptable to ordinary office practice.

during the treatment to replace chloride loss⁷ have converted this form of therapy from one requiring hospitalization to one in which the patient is usually able to return to his work on the day following treatment.

METHOD OF TREATMENT

During the last four years we have subjected 383 patients to 2,844 artificial fever treatments (approximately 16,000 hours of sustained fever). With the exception of occasional mild skin burns, which occurred particularly at the beginning of this undertaking, no person has been injured by the treatments. Of these, 175 patients have been treated for syphilis.⁸ Forty-three patients failed to cooperate, either during treatment or in the progress studies, the records of these patients are incomplete and are not included in this analysis. Forty-two patients have been under observation less than six months, these are also excluded from consideration. Sixteen patients with early syphilis have been treated with either fever therapy alone or chemotherapy alone, as control groups. One hundred and six syphilitic patients have been under observation for from six months to three and one-half years, these provide the data on which this report is based.

Many observers⁹ have found fever therapy combined with or followed by chemotherapy to be more effective than fever therapy alone in the treatment of neurosyphilis. On this basis we have combined chemotherapy, usually in the form of bismuth arsphenamine sulfonate (Bismarsen), with the fever treatments. In some patients neoarsphenamine and bismuth therapy was substituted. One advantage of the induction of artificial fever by physical methods is that the antisyphilitic drug may be given during the course of fever treatments. It is our practice to inject the antisyphilitic drug half an hour before the fever treatment is begun, on the basis that the general vasodilatation which occurs during sustained high fever may permit greater diffusion of the chemical substances. Bratz¹⁰ believes that fever produced by malaria increases the permeability of the small vessels of the brain and permits protective substances to reach the diseased brain tissues. After the ten sessions of fever therapy plus chemotherapy twenty injections of the antisyphilitic chemical agent are given, at weekly intervals.

We have regarded a minimum course of artificial fever therapy for patients with syphilis to consist of fifty hours of sustained fever between 105 and 106 F. This more or less arbitrary choice is based on the observation that the highest remission rate following malaria therapy occurred in patients who had experienced at least fifty hours of fever above 102 F. The treatments are usually given in ten weekly sessions, each of five or more hours' duration. Many patients experience the most marked improvement after five or six treatments, a few require more than ten.

All patients are subjected to a thorough diagnostic survey to determine eligibility for fever therapy. Special studies are made of cardiac, vascular and renal functions, including electrocardiographic, basal blood pressure and blood chemical analyses. Blood and spinal fluid serologic reactions, spinal fluid cell count, protein and sugar content, and colloidal gold reactions are determined before treatment is begun, at the end of the combined fever-chemotherapy regimen, and at intervals of six months thereafter. As an additional control measure duplicate blood and spinal fluid specimens from these patients were submitted to Kahn in the laboratories of the University of Michigan Hospital for repetition of the serologic examinations. The Kahn standard diagnostic, presumptive and quantitative procedures were carried out in those laboratories, without any knowledge of the clinical condition of the patients, and reported to us.¹¹ Old age (above 60 years), cardiac or renal insufficiency, advanced cardiovascular syphilis, aortic aneurysm, and the demented form of advanced dementia paralytica are regarded as contraindications. Patients between 45 and 60 years of age are treated with great caution. One or more mild treatments are usually given such individuals as a test of cardiac function. Occasionally treatments are spaced two weeks apart.

EARLY SYPHILIS

For centuries, laymen have known that sustained heat exerts a favorable influence on the cutaneous lesions of syphilis. The popularity of balneotherapy in many parts of the world has persisted since the ancient Greek priest-physicians first converted their thermal springs into baths. While emphasis has been placed on the mineral content of the waters, it now appears that the virtue of balneotherapy lies in its ability to produce local or general fever. The advent of scientific methods for the controlled production of fever provides a rational explanation for some of the results attained with the purely empirical use of these older methods.

Perhaps the first published observations on the artificial production of fever by balneotherapy appeared in 1884 in a paper by W. H. Phillips.¹² During a visit to Hot Springs, Ark., Phillips observed that patients who had remained in the sudatorium for long periods left with "faces flushed, eyes brightened, breathing hurriedly and sweating profusely." His curiosity aroused, Phillips experimented on himself. By gradually increasing the temperature of the bath water he elevated his mouth temperature to 103 F. At the conclusion of his stimulating paper, Phillips makes this prophetic remark: "Finally, it is when we are called upon to treat the more chronic forms of syphilitic disease that we are enabled to appreciate the immediate advantage of uniting these powerful constitutional agents [artificial fever and chemotherapy] for good."

There is a rapidly accumulating mass of experimental data which provides strong evidence of the unfavorable influence of high body temperature on *Spirochaeta pallida*. Many observers have reported their inability to find spirochetes in the brain tissue of patients who have died following malaria therapy.

In 1919 Weichbrodt and Jahnel¹³ placed rabbits with scrotal chancres in a thermostatically controlled incubator with the air temperature at 105.8 F. The temperature elevation in the rabbits induced by this procedure ranged from 104 to 107.6 F. The rabbits were subjected to this treatment for thirty minutes once or twice daily for from three to five weeks. After the second day the spirochetes gradually lost their motility, declined in number and disappeared. The chancres healed much more rapidly than in untreated rabbits.

Schamberg and his associates¹⁴ found that multiple hot baths exerted a favorable influence on syphilis of rabbits and human beings.

Bessemans¹⁵ of Ghent and his associates have made valuable studies which demonstrate the feeble thermoresistance of *Spirochaeta pallida*. With the ingenious use of small thermocouples inserted into the scrotal chancres of rabbits it was shown that primary syphilis was cured by either local or general balneotherapy or aérothermotherapy when the tissue temperature of the chancre was sustained at 104 F. for two hours or 107.6 F. for one hour. Raising the rabbits' intratesticular temperature to the same levels after inoculation prevented the development of the disease.

The important researches of Carpenter, Boak and Warren²⁰ again emphasize the thermolability of *Spirochaeta pallida* and "suggest the practicality of fever therapy in the treatment of acute as well as chronic syphilis in man." Utilizing heat produced by the short radio waves of an ultra-high frequency oscillator, they were able to prevent the development of chancres in twenty-one of twenty-five rabbits when treatments were begun four, five and seven days after inoculation. In one treated rabbit a chancre developed, while the testis of another became edematous and indurated, increasing the duration and number of heatings caused the rabbits to become normal, two rabbits died. Eighteen untreated control rabbits developed the typical lesions of experimental syphilis. These workers also found that multiple unsustained fevers of from 105.8 to 107.6 F. destroyed *Spirochaeta pallida* in rabbits with active

11 The Kahn quantitative procedure was found to provide a reliable and sensitive index of therapeutic response.

syphilitic lesions, as determined by reinoculation experiments. It was also found that one febrile period of six hours at a temperature of 106.7-107.6 F was sufficient to destroy *Spirochaeta pallida*. The time interval between inoculations and fever treatment, or between the end of fever treatment and reinoculation, did not affect the results. Hence the fever treatment was effective at any stage of experimental syphilis in rabbits. The same authors investigated the thermal death time gradient of *Spirochaeta pallida* in testicular extracts in vitro. Five hours of temperature at 102.2 F, three hours at 104 F, two hours at 105.8 F and one hour at 106.7 F were required to render infective material innocuous to other rabbits.

Levaditi and de Rothschild²¹ carried out somewhat similar experiments in which thermocouples were used to determine local temperature, with less constant results. In many of the rabbits rapid healing of the primary lesions, disappearance of spirochetes, sterilization of lymph glands and negative serologic reactions occurred. Levaditi regards artificial fever as an effective factor in stimulating the defense mechanism. Kolmer and Rule²² demonstrated that the testicular lesions were prevented and the inguinal lymph glands became sterile if rabbits inoculated intratesticularly with *Spirochaeta pallida* four days previously were immersed in water at 113 F for twenty minutes daily for fifteen days. If, however, the testicular lesions were kept out of the heated water, active syphilitic lesions developed. These authors²³ also found that fever of from 2 to 5 degrees F which lasted several hours and which was induced in the rabbit by intravenous injections of increasing amounts of typhoid-paratyphoid vaccine or Coley's fluid showed much less effect on the course of acute testicular syphilis than did fever induced by hot baths.

We have confirmed the observations of Carpenter, Boak and Warren by a somewhat different experiment. Six male rabbits were inoculated intratesticularly with fresh testicular extract containing the Nichols strain of *Spirochaeta pallida*. Only rabbits with negative Kahn and Kolmer serologic reactions were selected. Chancres or syphilomas developed in both testes of all the animals within four to six weeks. Aspiration revealed the presence of spirochetes in all. The serologic reactions of all were strongly positive at the end of eight weeks. Hemicastration of each rabbit was then done. The testicular emulsion derived from the extirpated testis of each of these six rabbits was then injected into the testes of each of a new series of six seronegative normal rabbits, all developed chancres and positive serologic reactions in the usual time. Immediately after hemicastration, the syphilitic rabbits were subjected individually to sustained rectal temperature of from 107.1 to 108.1 F, average 107.6 F, for six hours. 30-meter waves of a high frequency oscillator being used. The remaining testis was then removed from each rabbit four days after the fever treatment. Injection of testicular suspensions from each heated rabbit was made into the testes of each of a new series of seronegative normal rabbits, none developed evidence of syphilis, the serologic reactions of all remained negative.

It is quite conceivable that the same uniformity in results might not obtain following the application of fever therapy to human subjects. Syphilis in rabbits apparently pursues a somewhat milder course, generalized lesions and central nervous system involvement are comparatively rare. Nevertheless, these experimental studies provide incontrovertible evidence of the spirochetocidal effect of sustained high body temperature. Many observers are convinced that fever therapy is capable of producing a distinctly favorable influence on the progress of early syphilis, particularly when fever therapy is combined with orthodox chemotherapy. Kyrle²⁴ gave 232 seropositive patients with early syphilis (under two years' duration) a course of arsphenamine (from 4 to 6 Gm), followed by malaria therapy (ten chills), followed in turn by another course of arsphenamine therapy. The results were incomparably better than by any other method employed. Of the 232 seropositive patients with early syphilis, the blood serologic reactions were favorably influenced in 230 (99.1 per cent) after a single combined arsphenamine-malaria-arsphenamine course. Fifty-four of these patients had exhibited positive spinal fluid reactions. All were reversed to negative and remained negative. When Matuschka and Rosner²⁵ reported on the work of Kyrle after his untimely death, not one of these patients had relapsed, clinically or serologically, during five years of observation.

In the introduction to the Matuschka-Rosner monograph,²⁴ Finger makes this statement: "The results are significant. They show that in the early period of syphilis nothing influences the serum and spinal fluid reactions so favorably as combined malaria arsphenamine therapy, that a single course is usually sufficient and that the earlier the treatment is begun, the better are the results."

Kemp and Stokes²⁴ found that fever therapy induced by bacterial proteins, combined with arsphenamine therapy and followed by arsphenamine and bismuth therapy, offered a more satisfactory outlook in the treatment of early syphilis than routine chemotherapy alone.

Richet and Dublineau,²⁵ after experimentation with animals and human subjects, conclude that early syphilis may be "cured" more rapidly and more certainly by combined fever and chemotherapy than with chemotherapy alone. The blood serologic reactions of thirty-five of thirty-seven patients with primary and secondary syphilis became negative during or at the end of one course of pyretochemotherapy.

Wagner-Jauregg,²⁶ O'Leary,²⁶ Jacobs and Vohwinkel,²⁷ Bering²⁸ and others have repeatedly emphasized that the best form of treatment of neurosyphilis lies in its prevention by combined fever and chemotherapy during its asymptomatic phase. The extensive cooperative clinical studies carried out by Stokes, Cole

Moore, O'Leary, Wile, Clark, Parran and Usilton²⁹ reveal that abnormal spinal fluid conditions were present in 33 per cent of patients with early syphilis, and in 56.1 per cent of patients with late secondary syphilis. The same observers have also stated that "even thoroughgoing [chemical] treatment does not necessarily prevent the development of abnormalities of the spinal fluid"^{29b} and that in latent syphilis "almost all of the serologic response to be expected occurs within the first four months of treatment, thereafter further [chemical] treatment has little effect."^{29c}

On the basis of the foregoing observations it seems logical to conclude that the best results are obtained when combined fever and chemotherapy are applied early in the disease. With the hope that the disastrous late neurologic and visceral manifestations of the disease might be prevented, we have subjected twenty-six patients with primary and early secondary syphilis to the combined fever and chemotherapy regimen (fifty hours of sustained fever above 105 F and thirty injections of antisyphilitic chemotherapy). All these patients have been under observation for from six months to two and one-half years. None had received any previous treatment. As a control measure, six patients with primary or early secondary syphilis were treated with only fifty hours of fever therapy above 105 F. In two cases, clinical relapse (cutaneous eruption) occurred following the fever treatments, chemotherapy was promptly instituted. Of the four patients who have had fever therapy alone, the Kahn and Kolmer serologic reactions became less positive in three and more positive in one. The spinal fluid reactions remained negative in all.

A second control group of fourteen patients with primary or early secondary syphilis received only the thirty weekly injections of chemotherapy. Clinical evidence of relapse (cutaneous eruption) occurred in two patients, fever therapy was then given, with prompt remission of the skin lesions. Of the twelve patients who received only chemotherapy, the Kahn and Kolmer serologic reactions were reversed to negative in five, became less positive in six and became more positive in one. The spinal fluid reactions remained negative in eleven and were reversed to negative in one.

Including the four patients who were transferred from the two previous control groups, twenty-six patients with primary and early secondary syphilis were treated with combined fever and chemotherapy. The cutaneous manifestations of the disease, including the chancres, responded with surprising promptness (figs 2 and 3). The Kahn and Kolmer serologic reactions were reversed to negative in fourteen, became less positive in ten, remained positive in one and remained negative in one. The ten patients whose serologic reactions became less positive, and the one patient whose serologic reactions remained positive by the Kahn and Kolmer standard diagnostic tests have been under observation for only six to nine months. Progressive decline in the intensity of the serologic reactions, as measured by the Kahn quantitative procedure, has occurred in all. The spinal fluid reactions remained negative in twenty-three and were reversed to negative in three. There has been no evidence of clinical or serologic relapse in the patients treated with combined fever and chemotherapy.

With due regard to the small number of patients and the short interval of observation, these observations provide suggestive evidence that fever therapy alone or chemotherapy alone (as applied to these patients) is often inadequate. These observations also suggest that combined fever and chemotherapy is a distinctly advantageous form of treatment for early syphilis, particularly in those patients who do not respond promptly to orthodox chemotherapy. It must be appreciated that this is strictly a preliminary report of the response of early syphilis to combined fever and chemotherapy. Every effort will be exerted to follow the progress of these patients, and others who follow, throughout their lifetime.

Under existing circumstances, strong forces operate to keep the patient with early syphilis from receiving adequate treatment. It requires about eighteen months of continuous therapy in cases of early syphilis and an indefinitely longer period for the treatment of late syphilis.³⁰ The high cost and inconvenience to the patient often result in inadequate treatment. More than 500,000 persons in the United States seek treatment for early syphilis each year.³¹ Any method that would appreciably decrease the time and expense involved in providing adequate therapy is worthy of thoughtful consideration. A growing body of evidence appears to indicate that artificial fever therapy fortifies and intensifies the curative action of chemotherapeutic agents. The advent of simpler and safer methods for the induction and maintenance of artificial fever should stimulate vigorous investigation of this possibility.

NEUROSYPHILIS

Dementia Paralytica—Twenty patients with dementia paralytica have completed the course of fifty hours of fever therapy plus thirty injections of chemotherapy. Twelve have experienced complete clinical remission, two have been restored to a working status. Thus fourteen patients (70 per cent) have been socially rehabilitated. Four patients were accorded 50 per cent clinical improvement, two were regarded as having received 25 per cent improvement. No relapse has occurred following treatment. Six of these patients had advanced dementia paralytica, four had been committed to a hospital for the mentally diseased. Thirteen of the twenty patients had received presumably adequate chemotherapy, two had relapsed after receiving malaria therapy, five had received no treatment.

The Kahn and Kolmer serologic reactions were reversed to negative in four, became less positive in nine and remained positive in seven. Spinal fluid Kahn and Kolmer reactions were reversed to negative in five, became less positive in seven, remained positive in six, and became more strongly positive in two. The level of the colloidal gold reactions was reduced in twelve, elevated in three and unchanged in five.

As with fever therapy induced with malaria, there is no parallelism between the immediate clinical response and the serologic or colloidal gold reactions. In most instances the serologic reactions become negative or less positive during a period of several months following the treatment.

Tabes Dorsalis—The ten patients with tabes dorsalis had received chemotherapy previously. One had also received five malaria inoculations, followed by a temporary remission after the first inoculation. Two other patients had received malaria therapy. Ataxia (in nine

patients) and lancinating pains or gastric crises (in all) were the chief complaints. Two patients with ataxia of three months' duration in one case, and of two years' duration in the other, were restored to normal gait. Six patients obtained some improvement in gait while two showed no change. There appeared to be a direct relationship between the degree of improvement and the duration of the gait disturbance.

The root pains were abolished in all. Often the pains disappeared after the first two or three treatments. Recurrence of pains occurred in one patient after the usual course of treatments. This was controlled by additional treatments. Normal function was restored in one case of so-called cord bladder.

The Kahn and Kolmer serologic reactions were reversed to negative in four patients, became less positive in three, remained negative in one and remained positive in two. The spinal fluid reactions were reversed to negative in two, became less positive in three, remained positive in four and became more positive in one.

Tabetic Form of Dementia Paralytica—Seven patients with the tabetic form of dementia paralytica were subjected to the combined treatment. All had previously received chemotherapy, one had also had malaria therapy, followed by a remission lasting six months. Improvement in mental orientation occurred

Fig 1—The Kettering hypertherm

in six, one demented patient showed no improvement and died seven months after the treatment was completed. Subsidence of root pains occurred in all, in two instances additional fever treatment was required. Improvement in gait occurred in four of the five patients with ataxia, one patient who had had a tabetic gait for three months was restored to normal gait. One patient with a "cord bladder" regained normal control of bladder function.

The Kahn and Kolmer serologic reactions were reversed to negative in two instances, became less positive in one, remained negative in three and remained positive in one. The spinal fluid Kahn and Kolmer reactions were reversed to negative in four, became less positive in one and remained positive in two.

Fig 2—1 Appearance of hard chancre of penis March 23 1933 one day before pyretochemotherapy, numerous motile spirochetes. 2 Appearance of chancre March 26 two days after first treatment, no spirochetes present. 3 Appearance of chancre March 28 four days after first treatment, no spirochetes present. 4 Complete healing of chancre April 3 three days after second treatment.

Diffuse Central Nervous System Syphilis—In this group are placed thirteen patients with various manifestations of symptomatic neurosyphilis which could not be definitely classified as dementia paralytica, tabes dorsalis or the tabetic form of dementia paralytica. All but one had received antisyphilitic therapy. There were six cases of congenital syphilis and seven cases of acquired syphilis. In this group were nine cases in which ocular symptoms predominated.³³ Symptomatic remission occurred in nine of the thirteen patients, moderate improvement in three and no improvement in one. The Kahn and Kolmer serologic reactions were reversed to negative in one, became less positive in seven, remained positive in four and became more positive in one. The spinal fluid Kahn and Kolmer reactions were reversed to negative in five, remained negative in seven and remained positive in one.

Asymptomatic Neurosyphilis—Of seven patients with asymptomatic neurosyphilis, all of whom had previously received apparently ineffectual chemotherapy, the spinal fluid Kahn and Kolmer reactions were reversed to negative in six and became less positive in one. The blood Kolmer and Kahn reactions were reversed to negative in four, remained negative in two and remained positive in one. None have shown evidence of serologic relapse.

RESISTANT SEROPOSITIVE SYPHILIS

Included in this study were seven patients with so-called Wassermann-fast or what I prefer to term resistant seropositive syphilis. All had had presumably adequate chemotherapy. The Kahn and Kolmer serologic reactions were reduced to negative in four

33. The results obtained in these cases and in others manifesting ocular complications of syphilis will be discussed in a separate report by Arthur M. Culler and Walter M. Simpson in a forthcoming issue of the Archives of Ophthalmology.

became less positive in two and remained positive in one. The spinal fluid reactions remained negative in all. Serologic relapse has not occurred in any of these patients.

SUMMARY AND CONCLUSIONS

1 The value of artificially induced fever therapy as an adjunct to chemotherapy in the management of neurosyphilis is now firmly established. The one factor common to the wide variety of infectious, chemical and physical methods that have yielded comparable therapeutic results is simple fever production.

2 A simplified, controlled and relatively inexpensive method for fever induction and maintenance (Kettering hypertherm) has been devised. High frequency electric currents are not employed. During the past four years, 383 patients have been subjected to 2,844 artificial fever treatments, without any serious ill effects related to the method of treatment.

Fig. 3—1 Appearance of secondarily infected hard chancre of penis July 6 1933 the day before pyretochemotherapy numerous motile spirochetes. 2 Appearance of chancre July 10 three days after first treatment no spirochetes present. 3 Appearance of chancre July 15 one day following second treatment no spirochetes present. 4 Complete healing of chancre July 19 five days following second treatment.

3 The frequent observation that the best results occurred when neurosyphilis was treated by combined fever and chemotherapy during its earliest manifestations led us to apply the treatment to patients with primary or early secondary syphilis. The results provide evidence that fever therapy may be of great value in early syphilis, particularly when chemotherapy alone appears to be inadequate.

4 The results obtained in the treatment of symptomatic neurosyphilis, asymptomatic neurosyphilis and resistant seropositive syphilis are at least comparable to the results obtained with the more hazardous, time consuming and inconstant malaria therapy.

5 Hospitalization is not a requirement for fever therapy by physical means.

6 The advent of simple and safe methods for the production of artificial fever should stimulate vigorous investigation of the possibility that the time, effort and expense involved in the adequate antisyphilitic therapy may be greatly lessened.

7 There is evidence that artificial fever therapy fortifies and intensifies the action of antisyphilitic chemotherapeutic agents. It would appear that the therapeutic armamentarium of the syphilologist is now provided with a new and powerful weapon.

ABSTRACT OF DISCUSSION

DR. FRANK R. MENAGH, Detroit. The development of a practical air-conditioning cabinet that with the least discomfort to the patient will produce a controlled fever has been an achievement. The cabinet that Dr. Simpson and his associates have developed, with adequate apparatus for the easy control of temperature and relative humidity, has been at least in part responsible for the satisfactory results obtained. The accessibility of the patient for examination and treatment at all times is of great importance when it is remembered that the fever is maintained for five hours and that an extra hour is necessary to raise the temperature to 105 F or above. Since the autumn of 1933, my associates and I have had one or more of these hypertherms in our clinic and I wish to report our experience with one group of patients treated with this cabinet. Any one who follows the treatment of syphilis over a period of fifteen years gradually accumulates a group of problems in the form of patients who do not respond to the usual treatment with arsenicals, bismuth compounds, mercury and the iodides and in whom the malarial type of fever is inadvisable. A group of twenty-five such patients were given fever therapy. There were in this group twenty men and five women. They ranged in age from 17 to 63 years with an average age of 41 years. These patients had been under observation and treatment by us for an average period of four years and four months the longest period being more than ten years. These were given an average of 10.3 treatments each, a few receiving more than fifty hours of fever, and a few less. Twenty-one were given additional antisyphilitic therapy. As a result of treatment this especially refractory group showed twenty-two improved patients, two unimproved and one who died. The patient who died although he had syphilis was found at autopsy to have had a brain tumor. The two unimproved patients had tabes with tabetic pain and ataxia. They were thin, emaciated individuals and did not stand the fever well. In the improved group were eleven patients with syphilis of the parenchymatous type that is, positive spinal fluids with paretic gold curves, some of them with mild mental changes. This group did very well. Those with mental symptoms all improved, and at the present, one year after their treatment, none of the cases can be considered clinically active. This was the group that through the years had given us the greatest concern. There were six cases of tabes dorsalis, one with partial optic atrophy. The optic atrophy was arrested and apparently improved somewhat owing perhaps to the clearing of edema. I do not believe that any destroyed nerve fibers were ever regenerated. The remaining five patients never had a positive spinal fluid.

DR. CLARFANCE A. NEYMANN, Chicago. Momentous changes have come about since electropyrrexia was first introduced by Neymann and Osborne in 1929 based on researches begun in 1927. We have seen it develop into an accepted therapy for the treatment of certain diseases such as neurosyphilis and some forms of arthritis while we are not yet sure of its efficacy in a host of other conditions to which hyperpyrexia is being applied. In this connection I might mention early syphilis, asthma, chorea, minor gonorrhea and lately even malignant neoplasms. With the spread of the popularity of fever therapy induced by physical agents a great number of machines are being marketed. I believe that a perfect fever machine does not exist. As this therapy becomes better established, a more refined technique will undoubtedly be introduced. We have lately devised a cabinet the temperature of which closely approximates that of the patient's body at all times without in itself causing fever. We depend on electromagnetic induction for actually producing the fever. This method would seem to answer all questions of comfort and safety and yet not disturb the basic physiologic relationships which are reversed when ever external heat is applied. After all the external surface of the body is from 2 to 7 degrees F cooler than the interior.

The question of the modality or the machine used is of minor importance. The experience of the physician and his assistants is the main problem. I would stress the value of schooled personnel rather than the promotion of the use of a specific machine. I am sure that Dr Simpson agrees with me in this. During the last three years, Dr Theodore K Lawless, Mr S L Osborne and I have been working with primary syphilis. Chancres always disappear ten days after treatment with fever alone. Microscopic sections of chancres show spirochetes undergoing dissolution, both in the chancre and in concomitant inguinal lymph glands after one session of fever. I agree with Dr Simpson that fever therapy alone and chemotherapy alone are often inadequate for the treatment of all forms of syphilis both early and late. Bessemans, Van Haelst and De Wilde have shown that spirochetes found in the lymph glands of rabbits, guinea-pigs and mice are much more virulent and much more resistant to heat and chemotherapy than those obtained from concomitant chancres and skin lesions. These spirochetes have adjusted themselves to a more unfavorable environment. We have treated seven cases of primary syphilis with fever alone. Five of these developed late secondary syphilitic symptoms in the course of years. Two have remained free from all syphilitic manifestations.

DR. ALBERT N B LEMOINE Kansas City, Mo. Hyperpyrexia produced by malaria is one of the most valuable agents in the treatment of neurosyphilis. However as pointed out by Dr Simpson, it has disadvantages. Many of these can be overcome by production of fever by physical means. The various types of cabinets used have proved to be effective. However, the fact that a cabinet is necessary prohibits its universal use. Further many patients rebel against the prolonged treatment with these cabinets. To overcome these objections, Drs Charles Dennie and Polsky and I have adopted the hot bath treatment for cases of neurosyphilis and all manifestations of late or congenital syphilis. It has been found that such a course of treatment supplemented by chemotherapy gives much better results than was possible by chemotherapy alone. However we did not treat these patients with chemotherapy and the hot bath treatment at the same time, as did Dr Simpson. We used the hot bath treatment followed by chemotherapy. In some cases the results obtained were little short of miraculous. An ordinary tub is used in which the patient is submerged to the neck and covered with a poncho of light rubber. For the first hot bath the temperature of the water is started at 98 F and gradually increased to 102. This temperature is maintained for ten minutes. The second treatment two days later begins with a temperature of 100, is increased to 104 and is maintained for ten minutes at this temperature. The subsequent baths at two day intervals are all started at 100 and increased 4 degrees on each day, until 112 F is reached and maintained for fifteen minutes. This temperature should elevate the body temperature to over 104. In some cases a temperature of 106.5 was obtained. The best time to give these baths is just before retiring for the night. After the bath the patient should be immediately wrapped in a woollen blanket and allowed to cool off for an hour or two. We have found that maintaining the high temperature for fifteen minutes gives as good a result as an hour or two. The contraindications are the same as with the cabinet. We have treated cases of practically all types of late or congenital syphilis by this method that would not heal with chemotherapy, and all these latent cases of syphilis made remarkable improvement and the patients stayed well after using chemotherapy following the heat therapy. From this work we concluded that fever produced by the hot bath was a very effective therapeutic measure in late syphilitic lesions that were resistant to chemotherapy.

DR. M F ENGMAN JR St Louis. It seems rather difficult to divorce the foreign protein reaction or the thought of the foreign protein mechanism from all these heat applications. It is impossible to say that it is the heat alone which has accomplished the good results. In 1915 Dr Engman Sr began using shock therapy with typhoid in various diseases. He used it in lupus erythematosus annularis and in one or two cases of early syphilis. Later he conceived the idea of trying to mobilize in every way whatever defense mechanisms exist in the body against disease in an entirely nonspecific way. One of these methods was foreign protein injection that is typhoid serum

intravenously. Another was the use of iodide and he even thought that giving thyroid by mouth might increase the metabolism and help the desired result. So the idea was to do them all at once. We treated about thirty cases of early syphilis chancres and early secondary syphilis. We would prepare the patients with a high carbohydrate diet for a couple of days before the injection then have them on a small dosage of thyroid and on a moderate dose of iodide. Then the patients were given an injection of typhoid bacilli intravenously 25,000,000 then 50,000,000, 75,000,000 and so on, and a fever of about 102 to 105 was produced. When the fever reached its height, we gave 1 cc of 1 per cent mercury bichloride in physiologic solution of sodium chloride intravenously, hoping, as Dr Simpson mentioned that the increased capillary permeability would permit the mercury to have its desired effect. Our results in these thirty cases were not encouraging. We found that many of the patients would suffer from an almost toxic type of general debility. Some lost almost 25 pounds (11 Kg) not attributable to the syphilis. The quantitative Kahn reactions were reduced but with simultaneous studies in ordinary routine arsphenamine, and preparations of mercury and bismuth in the clinic this treatment was not as good, or if it was as good it was not superior. So we felt at the end that we might have benefited these patients somewhat. Then we put all of them on routine therapy, but our results in this routine were not particularly encouraging. We published the results in THE JOURNAL about four years ago.

DR. JOHN H STOKES Philadelphia. It should be pointed out that under no circumstances should the impression go out from this section or from syphilologists or fever therapists in general that primary and secondary syphilis are to be generally or uniformly dealt with by fever therapy. About all, it is unwise to create the impression that fever therapy can or should be expected in the near future to displace the now matured and carefully developed international and national systems for the chemotherapeutic management of early syphilis. This section and syphilologists in general can and I believe, should stand solidly for the application by all practitioners throughout the world of the standard worked out by the Health Organization of the League of Nations and the Cooperative Clinical Group with the United States Public Health Service in this country. These modes of treatment are supported by the largest material that has ever been accumulated and to their procedures and their conclusions for some time to come all other methods must be regarded as adjunct and subordinate. Especially is this true of the application of fever therapy to primary and secondary syphilis. These phases of the disease demand for their public health control chemotherapeutic methods of management which are accessible and easily available rather than esoteric and highly specialized. They must be applied on a grand in fact a universal scale. The effectiveness of such methods thus universally applied is no longer a matter for serious discussion or dispute. Fever therapy is fundamentally unable at the present time even granted a demonstrated comparable effectiveness to meet the situation as it stands. It is as its proponents repeatedly insist, a highly specialized form of procedure requiring special apparatus, trained personnel and centers for its application and there are comparatively few people equal to its responsibilities and few people able to avail themselves of its advantages. On the face of it this must for the time being discredit any procedure for the control of primary and secondary syphilis as a vast public health problem. The practitioner should treat early syphilis chemotherapeutically by the new standards and not vacillate over the possible but as yet unproved and comparatively inaccessible advantages of fever therapy in this phase of the disease.

DR. PAUL A O'LEARY Rochester Minn. I have observed Dr Simpson's work since its inception. The scientific manner in which he has studied these patients, not only while they are in the fever chamber but also subsequently to note the serologic results is worthy of comment. I think that his suggestion in regard to the use of saline solution by mouth during the course of fever has been of material value not only to patients in the hyperthermia chamber but also to those who are undergoing malaria therapy. There is nothing for the mechanotherapists the fever therapists and the chemotherapists to argue about so

far as the results of the treatment of syphilis are concerned The therapeutic results from malaria and treatment with the fever-producing units are quite similar Likewise, the unfavorable results from treatment with these units and with malaria are comparable. There are about 10 per cent of patients who cannot take malaria and about 10 per cent of patients who cannot tolerate these various fever units I think that the argument against malaria, viz , that it requires hospitalization, is not a very valid one, since for malaria therapy from twelve to fourteen days in the hospital is required at one time in contrast to a day in the hospital every week for a similar total for the hypertherm treatment Hence we fever therapists have nothing to argue about, we are all in accord The only point that we have to discuss is the mechanism by which these results are produced, and unfortunately we dont know very much about this I have been more interested in malaria therapy because I felt that there was a biologic interreaction of some sort between Spirochaeta pallida and Plasmodium vivax, the nature of which is unknown The part played by the reticulo-endothelial system or the changes in the plasmocytes has been suggested, but neither of these theories is established as yet I have felt, however that fever alone was not the sole cause of the therapeutic effects because I have observed that patients who underwent malaria therapy for active neurosyphilis which appeared during the stage of acute syphilis have developed cutaneous and mucous membrane recurrences six months or more after the fever treatment, likewise the appearance of cutaneous gumma in parietic patients following fever therapy is evidence that the spirochetes were not destroyed by the heat” Even more significant is the fact that the good results from fever therapy require a year or more to develop they do not appear in a few weeks or months as is noted following the use of arsphenamine Perhaps the biologic reaction is a catabolic one the result of the destructive process that occurs as a consequence of the fever

DR. WALTER M SIMPSON Dayton Ohio As Wade Brown, Louise Pearce and others have pointed out, there is no chemical agent that will insure complete sterilization in the treatment of syphilis It is apparent that the action of antisyphilitic chemo therapeutic agents is to stimulate natural immune processes Fever therapy apparently provides an additional immunologic stimulus It is quite possible that patients with early syphilis have been given too much fever therapy It is quite conceivable that a smaller amount of artificial fever would be equally effective The treatment of a series of early syphilitic patients has been begun, ten fever treatments being given at intervals of from three to five days of two and one-half to three hours duration at from 105 to 106 F, combined with chemotherapy (total dosage of 9 Gm of neoarsphenamine and 6 Gm of metallic bismuth) The least important factor in artificial fever therapy is the apparatus The potentialities for harm in the hands of unskilled or unscrupulous persons probably exceed any benefits that might be derived from it The application of fever therapy to early syphilis should be regarded as a strictly experimental undertaking for the next several years I am glad that Dr Stokes referred to the public health aspects of this problem Physicians now have at their command the means with which to abolish syphilis and gonorrhea from the face of the earth Little can be accomplished, however until the public has been aroused as to the appalling disasters wrought by these diseases Wide publicity has been the most potent weapon in the successful warfare against smallpox yellow fever, typhoid, diphtheria and tuberculosis The gains that are now being made in the fight against cancer are due to a large measure to organized lay publicity No great gains can be made in the conquest of syphilis and gonorrhea until the unreasonable prejudice against the dissemination of sound information to the millions of actual and potential victims of these diseases has been abolished. To regard these diseases as just punishment for sinfulness is to deny the innocent acquisition of these diseases in a great proportion of cases Organized molding of public opinion is a fundamental requirement if the enormous human wastage due to the present lack of control of these diseases is to be prevented New heights of absurdity were reached recently when a radio broadcasting company refused to permit an acknowledged authority to deliver a speech on the public health aspects of the problem because the word ‘syphilis’ was to be mentioned

GROWTH ARREST IN LONG BONES AS
RESULT OF FRACTURES THAT
INCLUDE THE EPIPHYSIS

EDWARD L COMPERE, M.D
CHICAGO

The importance of the growth cartilage of the long bones has been emphasized by embryologists and anatomists, but the ease with which growth may be arrested as the result of infection that injures the cartilage plate or by direct violence, which may be produced by the surgeon who is careless in his operative approach or may be secondary to fractures or crushing injuries in the region of the ends of the long bones, is not always appreciated by those who are called on to treat the lesions of the extremities of growing children

Haas¹ has stated that trauma is the most frequent cause of disturbances of growth in bones He further states that the greatest growth activity is localized in the cartilage columns on the metaphyseal side of the epiphyseal cartilage plate and that, after the destruction of this portion of the growth cartilage, length growth practically terminates In a series of experiments on young dogs and cats in which he damaged the

* Includes five pathologic fractures

growth cartilage itself, the epiphysis or the metaphysis in various ways, he found that injury to the epiphysis alone or to the metaphysis alone caused very little change in the rate or extent of growth of the extremity On the other hand, injuries in the shaft of the bone that extended to and across the epiphyseal line, injuries to the epiphysis that included in the applied trauma a portion of the cartilage plate, or direct insult to the growth cartilage alone did cause an early closure or a complete arrest of growth from the traumatized end of the bone

Gatewood and Mullen² have also shown that immediate closure of the epiphyses resulted from the destruction of the epiphyseal cartilage plate on the side nearest the joint Interruption of the extrinsic blood supply to the epiphysis, by stripping away the periosteum at the site of the epiphyseal cartilage, caused this epiphysis to fuse to the shaft earlier than in the control limb, although there was no immediate arrest of growth

Haas has also warned against the stripping of soft parts from the edges of the epiphyseal cartilage plate. He has stated that surgery of the extremities of chil

dren that did not take into consideration the danger of growth arrest has caused many growth disturbances and deformities. He demonstrated in experimental work that the mere passage of sutures through the actively growing columns of cartilage cells of the cartilage plate resulted in the arrest of growth.

During the seven and one-half years since the opening of the clinics at the University of Chicago, I have seen a group of cases showing deformities that developed as a result of fractures that crossed the epiphyseal cartilage and produced partial or complete growth arrest. Growth disturbances due to fractures

*Two of the fractures were too recent to determine fate of the growth cartilage and ten patients (twelve fractures) had moved without leaving addresses or were otherwise lost.

Lewin³ in 1929 published a comprehensive review of the growth, development, injuries and diseases of the epiphyses, but he did not discuss growth disturbance secondary to fractures that involved the epiphyseal cartilage.

Elmslie,⁴ Reschke⁵ and Speed⁶ have reported cases of arrest of growth of long bones from simple fractures that extended across the cartilage plate. However, no analysis of a significant series of fracture cases to determine the incidence in which fractures in children have involved the growth cartilages or have resulted in growth disturbances has been reported.

were thought to be relatively uncommon, but factual data to support this belief could not be found. A study of all the fractures of the long bones that had been treated in the University of Chicago Clinics from October 1927 to May 1935 to determine as nearly as possible the incidence of fractures with growth arrest was made. The results of this study are shown in table 1. Patients treated for fractures of the long bones reached a total of 693, with a total number of 819 fractures, 211, or 34 per cent of the total number of fracture cases studied, were in children 14 years of age or younger at the time the fracture occurred. In this group of children were 290, or 35 per cent of the total number of fractures. In thirty-seven of the 211 cases, the fracture involved the growth cartilage.

TABLE 4—Location of Fractures of Epiphyses or Fractures of the Shaft That Crossed the Epiphyseal Line, in Children

| | |
|--------------------------------------|----|
| Humerus (1 proximal 11 distal) | 12 |
| Radius (2 proximal 6 distal) | 8 |
| Ulna (distal) | 2 |
| Femur (4 distal 2 capital epiphysis) | 6 |
| Tibia (distal) | 9 |
| Fibula (distal) | 5 |
| Total | 42 |

In this group of thirty-seven patients there were forty-two such fractures, an incidence of 14.4 per cent of all the fractures in children.

Table 2 includes all the patients 14 years of age or younger at the time the fracture occurred who have been seen in this clinic because of an old fracture of a long bone that resulted in growth arrest and

deformity or recent fractures that definitely included the growth cartilage

An analysis of the cases that are listed in this table is given in table 3. The total number of fractures observed in children that involved the growth cartilage was found to be forty-two, which, as previously mentioned is about 14 per cent of all the fractures of the

Fig. 1 (case 1)—Reversal of the carrying angle of the left arm. May 11 1935 due to the retarded and finally arrested growth of the medial condyle of the humerus

long bones in children which have come to this clinic. Of this number eight were old fractures admitted because of deformity due to arrest of growth. Three of the eight had been compound fractures, so that the growth cartilage was injured by the infection as well as by trauma from the fracture. Of the entire group of forty-two fractures, five were complicated by infection, in all of which growth was arrested. There were thirty-three fractures in which the epiphyseal cartilage was involved but were too recent to show deformity at the time of the first admission. In only nineteen of these have we been able to secure an adequate roentgen follow-up examination. Of the nineteen, eighteen have shown definite growth arrest, an incidence of 95 per cent.

In table 4 the location of the various fractures that involved the growth cartilage are shown. The most common fracture to extend across the epiphyseal line into the epiphysis is that of the distal end of the humerus, while the bone that is least often injured in this way, as judged by this rather brief series of cases, is the ulna.

The following cases are illustrative of the growth disturbances that may result from fractures which include the growth cartilages.

REPORT OF CASES

CASE 1—A B, a boy, aged 10 years, sustained a fracture of the lower end of the left humerus Aug 6 1932. Roentgenograms taken immediately after the injury showed a transverse supracondylar fracture and a split downward through the distal fragment across the epiphyseal cartilage into the joint. A satisfactory reduction was obtained. Following removal of

the cast, the distal fragment angulated posteriorly. The patient recovered complete extension and flexion through an arc of 130 degrees. In January 1934, roentgen examination revealed loss of the normal carrying angle of the left elbow. This cubitus varus deformity has slowly increased, owing to normal growth of the radial half of the distal humeral epiphysis and retarded growth of the medial half. Roentgen examination May 11, 1935, showed fusion of the medial portion of the distal growth epiphysis to the lower end of the shaft of the humerus (fig 1).

CASE 2—D A, a boy, aged 13 years, seen at the University of Chicago Clinics, Feb 8 1934, fell from a viaduct, July 19 1929, and both arms were fractured at the wrist (fig 2). Both fractures were reduced and union occurred. Normal function was restored in the right arm. Three years later the mother of the patient observed that the left arm was deformed at the wrist, with the hand deviating toward the radial side. A roentgenogram taken at this time showed fusion of the distal epiphysis to the metaphysis of the radius. Roentgenograms taken on admission to the University of Chicago Clinics (fig 3) showed shortening of the shaft of the left radius, fusion of the distal radial epiphysis to the metaphysis and deformity with radial deviation of the hand resulting from continued growth of the ulna. Arrest of growth of the ulna by excision of the distal end of the shaft was advised.

CASE 3—J W, a girl aged 8 years, was struck by a truck, Dec 11 1933, and was brought into the hospital unconscious. The right knee was painful and swollen. A roentgen examination showed backward displacement of the lower epiphysis of the right femur of about 1 cm and a simple fracture, without displacement, of the distal shaft, the cartilage plate and the epiphysis. The displacement of the epiphysis was reduced by extension traction, and a plaster cast was worn for five weeks. The patient recovered normal and painless function of the knee. She was last examined May 17 1935, and at this time she walked without any limp and had normal function. A roentgen examination May 16 1935, showed narrowing of the epiphyseal line and fusion of the lateral condyle to the shaft. This injury to the cartilage may result in growth arrest of the lateral condyle of the femur. Continued growth of the medial condyle will thus produce a genu valgum deformity.

Fig. 2 (case 2)—Fracture dislocation of the distal epiphysis of the left radius. July 26 1929

CASE 4—W L, a boy aged 15 years, admitted in July 1933 was struck by a car about two years prior to admission and sustained an injury to his right knee. Subsequently he developed a progressive right genu valgum deformity. Roentgenograms taken the day of admission showed unequal growth of the right lower femoral condyles, with the lateral shorter than the medial condyle (fig 4). Interpretation of these roentgenograms and the history led to the impression that the patient had sustained an incomplete fracture of the lower end of the

femur similar to that described in case 3, with arrest of growth of the lateral condyle. Correction was by supracondylar osteotomy.

CASE 5—I. M., a boy, aged 14 years, came to the University of Chicago Clinics because of a flexion deformity and 2 inches shortening of the right leg. Seven years before this admission he had fallen, sustaining a fracture of the lower end of the right femur with displacement of the femoral epiphysis (fig 5).

Fig 3 (case 2)—Appearance Feb. 8, 1934, five years after the fracture. There has been no further growth of the left radius from its distal epiphysis and the growth of the ulna has increased the deformity of the wrist.

Roentgenograms showed that it was accurately reduced. Subsequently the epiphysis became fused posteriorly to the shaft of the femur. Growth continued from the anterior portion of the distal growth cartilage but was retarded in the posterior portion. As a result of this the condyles became gradually tilted backward so that the proximal end of the tibia articulated with the femoral condyles in a posterior position and it was not possible for the patient to extend the leg more than 160 degrees. An operation for lengthening the femur similar to the technique described by Putti but with the addition of a full thickness tibial bone graft which would reinforce the femur in the region of the osteotomy, was performed Nov. 6, 1934. At this time an attempt was made to correct at the site of the osteotomy, the posterior displacement of the lower femoral epiphysis. The operation was successfully performed and approximately 2 inches of length was obtained by fixed skeletal traction continued for four weeks. The patient is now walking and is able to extend this leg completely.

CASE 6—K. S., a girl, aged 9 years, had growth arrest of the distal fibula and tibia. The patient fell while playing at school Oct. 16, 1934. Roentgen examination showed a fracture of the lower end of the tibia and across the epiphyseal cartilage into the epiphysis. There was also a fracture through the epiphyseal line at the distal end of the fibula with about 3 mm medial displacement of this epiphysis. Immobilization in a plaster cast was continued for one month. Weight bearing was permitted after six weeks. Restoration of normal function was accomplished, but roentgen examination, May 16, 1935, showed narrowing and irregularity through the line of the growth cartilage with beginning fusion of the epiphysis to the shafts of both the fibula and the tibia.

CASE 7—D. W., a girl, aged 12, sustained a simple fracture of the distal portion of the shaft of the left tibia and fibula Oct. 28, 1934. The fracture included the epiphyseal cartilage of both bones. A roentgenogram April 13, 1935, revealed smooth articular surfaces and there was no deformity. The epiphyses of both the tibia and the fibula have fused to the metaphyses. Since this patient is physically more mature than her age would indicate, not more than 1 to 2 cm of shortening of the leg is anticipated.

CASE 8—W. M., a boy, aged 14 years, came to the University of Chicago Clinics, Jan. 6, 1934, because of a progressively increasing deformity of the right ankle. Two years before, he had sustained a fracture of the tibia. Roentgen examina-

tion at that time showed that the fracture line had crossed the epiphyseal cartilage and the epiphysis and entered the ankle joint at its medial side (fig. 6-4). Roentgenograms which were taken at the time of his admission to the clinic showed an arrestment of the growth of the medial malleolus of the tibia (fig. 6-1). The lateral two thirds of the lower end of the tibia had continued to grow and the astragalus had become rotated medially toward the defect produced by the arrest of growth of the medial malleolus. A transverse line across the shaft of the tibia about 15 cm above the open epiphyseal line of the growing epiphysis and approximately directly continuous with the epiphyseal line of the growth arrested medial portion of the distal end of the tibia was interpreted as the site of the epiphyseal cartilage at the time of the injury and to have been produced by temporary arrestment of growth due to the fracture.

Jan. 29, 1934, an attempt was made to correct the varus deformity of the foot and to arthrodese the astragalus to the growing portion of the tibia. The deformity was corrected and the astragalus became fused to the growing portion of the epiphysis. The patient began to walk without crutches and without mechanical support for the foot, six months after the operation. Three months later he fell and sustained a spiral fracture of the tibia just above the distal epiphysis but this time the fracture line did not cross the growth cartilage. The second fracture united and for the past seven months the patient has walked without discomfort and only a slight limp. The last roentgen examination was made May 16, 1935, and showed that the deformity had not recurred. The astragalus is now firmly united to the growing portion of the tibia; the right leg is

Fig 4 (case 4)—Condition Aug. 29, 1933, two years after the injury, showing growth arrest of the lateral condyle of the femur with the development of a marked genu valgum deformity.

approximately 0.5 cm shorter than the left and there is no obvious disability (fig. 7). At his last visit in the clinics he requested permission to try for football at school next year.

CASE 9—G. D., a boy, aged 16, with growth arrest from operative trauma, came to the University of Chicago Clinics in 1930 at the age of 11 years because of a deformed left foot and short left leg. He had been born with a calcaneus deformity and was operated on at the age of 2 months, again at the age of 5 months, and a third time at the age of 8 months.

The exact nature of these operations could not be learned. The calcaneus position was not corrected, and after the operations the left leg grew more slowly than the right.

My examination revealed a marked deformity of the foot and an extreme calcaneus position (fig 9A). The left leg, measuring from the anterior superior spine to the medial malleolus, was found to be $3\frac{1}{2}$ inches longer than the right. A roentgenogram of the left foot revealed gross deformities consisting of absence of part of the talus, some of the midtarsal bones, and the distal epiphyses of the tibia and the fibula.

Fig 5 (case 5) —Condition Oct 31 1934 showing angulation posteriorly of the distal end of the femur due to growth arrest posteriorly while the growth cartilage in the anterior region has remained active. The epiphysis has now completely fused to the shaft of the femur while the epiphyseal lines at the proximal end of the tibia and fibula are still open. As a result of this growth disturbance there is shortening of 2 inches in this femur and extension of the knee is limited to 160 degrees.

The parents had been told by the surgeon who operated when the child was an infant that he had shortened the bones of the leg in order to correct the calcaneus deformity. Obviously he was ignorant of the importance of the growth epiphyses and had deliberately chopped them off or crushed them in an attempt to correct the deformity forcibly.

After a futile attempt to correct the calcaneus position by a turnbuckle brace, I performed a wedge resection through the remaining midtarsal bones and displaced the foot posteriorly under the astragalus. This operation made it possible for the patient to walk on the plantar surface of the foot. In addition to this the growth epiphyses at the lower end of the right femur and proximal ends of the right tibia and fibula were fused to the shaft by the method that has been described by Phemister⁷. At the time of this operation Jan 29 1932 the left leg was $3\frac{1}{2}$ inches shorter than the right. Teleroentgenogram measurements were last made Feb 14, 1934, two years and one month after arrest of the growth epiphyses at the right knee. These measurements showed that there had been a retardation of growth of the right leg so that the left leg had gained 2 inches. He now walks well, wears a standard oxford shoe and has little functional disability (fig 8B).

COMMENT

Textbooks have been notably lacking in warning of the dangers to the growth cartilage from fractures which include this portion of the long bone.

⁷ Phemister D. B. Operative Arrestment of Longitudinal Growth of Bones in the Treatment of Deformities. *J Bone & Joint Surg* 15: 115 (Jan) 1933.

Reschke has reported a brief series of cases of growth disturbances that resulted from fractures of the ends of the long bones in growing children. Elmslie reported one case of a fracture with growth arrest of the distal end of the tibia, while Speed has discussed the growth deformities that result from fractures of the distal end of the humerus. Snyder reported growth arrest from unilateral surgical trauma to the epiphyseal cartilage plate of the long bones of children. For correction of the deformities he recommended unilateral arrest of the cartilage plate of the opposite side or the use of braces or casts, which would be worn until growth ceased.

Phemister has recommended growth arrest of epiphyses of the longer leg in cases of inequality of leg length in children. He has also successfully performed growth arrest of a more rapidly growing unilateral portion of one epiphysis to correct deformity. Growth arrest operations were performed in case 9, in which there was $3\frac{1}{2}$ inches of shortening of one extremity due to surgical trauma to the distal end of the tibia and fibula when the patient was less than 1 year of age. This operation, which consisted of the arrest of growth of the distal epiphysis of the femur of the longer leg and the proximal epiphyses of the tibia and fibula, resulted in partial equalization of the length of the two legs.

I have not seen in a clinical case an example of the condition which Hans Selye⁸ has described in rats. Selye has shown that, if the distal end of the femur is removed during the first few weeks of life in the rat, a new growth cartilage is formed and the growth in length is resumed. This new growth cartilage forms always in a plane at right angles to the shaft, irrespec-

Fig 6 (case 8) —A injury of the medial portion of the distal epiphysis of the tibia Sept 23 1931 which extends across the epiphyseal cartilage but cannot be seen to include the metaphysis. The epiphysis of the fibula has been dislocated medially. B Jan 6 1934 two years after the fracture. The medial portion of the epiphysis has become fused to the metaphysis. There is a transverse line across the tibia 1 cm. above to the metaphysis. This is the open epiphyseal line of the growing portion of the tibia and this is directly continuous with the fused epiphyseal line in the medial portion of the tibia. This is attributed to the temporary cessation of longitudinal growth of this bone which immediately followed the injury.

tive of the plane of the amputation. In case 9 of the present series the distal epiphyses of the tibia and fibula were excised when the patient was less than 1 year of

⁸ Selye Hans. On the Mechanism Controlling the Growth in Length of the Long Bones. *J Anatomy* 68: 289-292 (April) 1934.

age. I was not able to secure interval roentgenograms but when the patient was 11 years of age, at the time of his first visit to the clinic there was no evidence of a growth cartilage that could be seen in the roentgenograms of the distal ends of these two bones. The shortening that had resulted was as much as would have been expected from complete absence of any growth from the distal epiphyses of the tibia and fibula.

Gilhes⁹ has shown that the characteristic fractures in the region of the wrist in childhood are either trans-

verse or torus, the point of fracture being above the site of the classic radius fracture in adults. This has been found to be true in my own series and since fractures of this type do not disturb the longitudinal growth of bone, it would seem to be a fortunate circumstance.

Birth fractures or those which occur during infancy, are commonly of the transverse type and are shown by Truesdell¹⁰ to be located in the midshaft region. None of the birth fractures reported by Truesdell included the end of a long bone. The youngest patient in the present series in which the fracture included growth cartilage was $4\frac{1}{2}$ years of age. The average age was $9\frac{1}{2}$ years. Since it has been shown that growth may continue for from one to three years after such an injury before the premature closure of the epiphyseal line occurs in only a relatively small percentage of the cases in which growth is arrested by

Fig. 7 (case 8)—The deformity noted in figure 6 B has been corrected. The astragalus is now firmly united to the growing portion of the distal epiphysis of the tibia. The distal epiphyses of both the right tibia and the right fibula have become fused to the shafts while the epiphyseal lines of the left tibia and fibula are open.

verse or torus, the point of fracture being above the site of the classic radius fracture in adults. This has been found to be true in my own series and since fractures of this type do not disturb the longitudinal growth of bone, it would seem to be a fortunate circumstance.

Fractures of the epiphyseal cartilage of the long bones do not necessarily cause immediate arrest of growth. Growth disturbances may not be apparent six months or even a year after the fracture, but the epiphysis may be expected to fuse earlier than on the uninjured side. Instances of this have been noted in the present series. One year after the fracture in case 1 there was no evidence of a growth arrest but three years afterward the epiphysis had fused, while the distal epiphyseal line of the uninjured humerus was still open. In case 3, six months after the fracture, a roentgenogram was taken which did not show a growth disturbance. One year and five months after the fracture had occurred however, a roentgenogram showed definite fusion of the lateral condyle. In case 5 there was a deformity due to an early fusion of the posterior portion of the epiphysis of the femoral condyle, while growth continued anteriorly and resulted in tilting the condyles of the femur backward, but after two or three years of continued growth of the anterior portion this also fused, while the longitudinal growth continued in the normal leg and resulted in 2 inches of shortening of the femur in which the fracture had occurred. A somewhat similar condition was noted in case 8. Two years after the fracture had occurred, a roentgenogram showed complete growth arrest of the medial portion of the distal epiphysis of the tibia, but growth had continued at approximately a normal rate

Fig. 8 (case 9)—A, condition in 1932. The left leg is $3\frac{1}{2}$ inches shorter than the right because of trauma to the distal epiphysis of the tibia and fibula from an operation during infancy to correct a calcaneus deformity of the foot. B, condition in 1934, two years after operation for fusion of the distal epiphysis of the right femur and the proximal epiphyses of the right tibia and fibula. The difference in the length of the two legs is now $1\frac{1}{2}$ inches.

such fractures will there be an appreciable deformity. Those cases in which the fracture occurs after the age of 12 years, even though growth may be arrested, would be expected to result in a minimal degree of deformity.

⁹ Gilhes, Carl I. Fractures in the Region of the Wrist in Childhood, Puberty and Adolescence. J. Iowa M. Soc. 23: 15 (Jan.) 1935.

¹⁰ Truesdell, E. D. Birth Fractures and Epiphyseal Dislocations. New York: Paul B. Hoeber, 1917.

Truesdell has reported a series of cases in which there were dislocations of the cartilaginous epiphyses as a result of birth trauma. In some of these deformity, but no serious disturbance of growth persisted throughout infancy. None of the cases reported had been followed until growth was complete. There was a striking tendency in these cases studied by Truesdell for the construction of new shafts of the long bones between the dislocated but invisible cartilaginous epiphysis and the epiphysis at the other end of the bone so that for a time the roentgenograms showed a double shaft with subsequent absorption of the older bone.

CONCLUSIONS

1 About 35 per cent of all the fractures that have been treated in this clinic occurred in children 14 years of age or younger.

2 Fourteen per cent of the fractures in children involved the growth epiphysis.

3 Of the fractures in children that involved the growth cartilage and were seen before deformity had occurred and were followed for more than six months with roentgen examinations, eighteen of nineteen cases, or 95 per cent showed growth disturbances.

4 Growth disturbance from fractures near the ends of the long bones in children are more common than is generally recognized.

5 The clinician should be reserved in his prognosis in the cases of such fractures and should follow these patients with periodic roentgen examinations for from one to two years after union of the fracture has taken place.

950 East Fifty-Ninth Street

ABSTRACT OF DISCUSSION

DR F. C. KIDNER, Detroit. Dr Compere's statistical study of the harmful effect on growth of injury to the epiphyseal line of long bones focuses attention on a condition that surgeons rarely recognize. It first came under my observation in 1918 when I saw a girl of 17 whose left foot was in such extreme supination that she walked on the outer border of her foot, the external malleolus almost touching the ground. She injured her ankle ten years before. The deformity developed gradually. There was a sharp, inward angulation of the lower end of the tibia so that its lower articular surface was at an angle of 45 degrees with the shaft. The fibula, which was much longer than the tibia, had grown like a bow around the ankle joint. It seemed probable that the original trauma had stopped the growth of the lower tibial epiphysis completely and that the deformity was the result of adaptive changes incident to the excessive growth of the fibula. Simple osteotomy of the inner border of the tibia and osteotomy of the fibula allowed correction. A recent case of a girl of 12 with almost no disability shows an extreme outward tilting of the astragalus apparently resulting from loss of growth of the outer half of the lower tibial epiphysis. The inner half and the epiphysis of the fibula have grown equally so that the general alignment is good. The extreme tilt of the astragalus has been compensated by adaptive growth of the whole tarsus so that the weight bearing and function are excellent. These and other experiences with deformities following epiphyseal fracture at the knee, elbow and ankle have been sufficiently common to lead me to warn the parents of children with such fractures that such deformities are possible. I have always felt that traumatic rupture of blood vessels with resultant poor circulation to a part or all of the epiphyses is the determining factor rather than actual injury to the cartilage cells. The best hope of prevention lies in accurate, gentle reduction of the fracture, followed by long periods of fixation and prolonged delay in weight bearing. My rule in epiphyseal fractures is not to allow weight bearing in less than three months.

DR J. DEWEY BISGARD, Omaha. It has been known since the studies of Stephen Hale in 1747 that all growth in the length of long bones takes place by deposition of new bone at the diaphyseal extremities, also that this growth is unequal from the two ends of each long bone. The proportion of growth that takes place at each end has been calculated by Digby from measurements made from each end to the point at which the nutrient canal, when projected, intersects the center of the medullary canal. The accuracy of these calculations I was able to affirm experimentally. If growth is arrested at the end of a bone that contributes very little growth, little or no deformity from shortening results whereas the converse is likewise true. Angulation and torsion deformities such as varus and valgus develop from asymmetrical growth arrest. Injuries and inflammatory lesions near the epiphyseal line often stimulate rather than retard growth and may cause deformity from overgrowth of an extremity. Overgrowth not infrequently prevents deformity by compensating for shortening of a bone in which a fracture has united with the fragments overriding. I wish to emphasize the importance of another type of injury which occasionally causes arrest deformity, and that is excessive roentgen and radium irradiation. The cells of the epiphyseal cartilage are moderately radiosensitive, so that therapeutic irradiation over or near the cartilage should be carried on with caution.

DR EDWARD L. COMPERE, Chicago. It is fortunate that fractures in children are mostly of the shaft. In the University of Chicago Clinics 86 per cent of the fractures in children were of this type and did not reach the region of the growth cartilage. Of the 14 per cent that did cross the epiphyseal cartilage, eighteen of the nineteen cases did show arrested growth. Fortunately, most of these patients were approaching the limit of their growth period before growth was arrested, which accounts for the fact that not many of them developed marked deformities. Three per cent of all cases of fracture in children did have growth deformities that required correction. Truesdell in his book on fractures and epiphyseal dislocations in the newborn did not report a single instance in which the fracture involved the epiphyseal line. They were all midshaft fractures. As the patient grows older the incidence of fractures that involve the epiphyseal line increases, but the danger of deformity is less, since the residual growth period is shorter. Deformity from growth arrest due to fracture, infection or surgical trauma is likely to be a late result after the case has been discharged. Unless the surgeon is wise enough to continue to follow all cases treated for a lesion that involves an epiphyseal cartilage for several years or until their full growth has been attained the patients may seek advice from other physicians when the deformity becomes apparent. When I was 11 years of age, I had osteomyelitis of the femur and was operated on by a doctor who didn't know about the epiphyseal line. The knife incision reached to the level of the knee joint on the inner side of the femur. As far as I can tell from subsequent roentgenograms the disease itself did not involve the epiphysis or the epiphyseal cartilage. Three years after the osteomyelitis had entirely healed the leg was straight and there was no evidence of growth deformity. About the age of 15 the leg began to be bowed. There was then no shortening that I could detect. The growth was first arrested on the medial side where the operation crossed the epiphyseal line, while it continued for a time on the lateral side. Subsequently it was arrested laterally also while the left leg continued to grow, so that I now have a shortening of 1 inch in addition to the outward bow of the femur. The injury to the growth cartilage led to premature closure of the epiphyseal line, but deformity was not observed until three years later. In cases of fracture or insult to the epiphyseal cartilage from any cause, patients should not be allowed to bear weight for several months and guarded prognosis should be made.

Precordial Pain—The very first symptom of which a patient may complain when the myocardium begins to fail and before the patient has reason to believe that his heart is not doing its work, is precordial pain without hypertension.—Dr Henry Mohler, quoted by Fisher, Alexander. *Aphorisms in Clinical Medicine Canad J Med & Surg* 77 166 (June) 1935.

HEALING OF THE NEWER BUMPER FRACTURES OF THE TIBIA

WALTER G. STERN, M.D.
AND
LOUIS E. PAPURT, M.D.
CLEVELAND

The popularity of the automobile as a locomotive agency has made it our greatest destructive force and changes in design have immediately been reflected by changes in the type character and relative frequency of the various resultant fractures. The great importance of the automotive factor in traumatic and fracture surgery is readily recognized when one realizes that in 1934 there were 1,250,000 nonfatal automobile accidents. This is 16 2/3 per cent of all nonfatal accidents occurring in the United States.

In the early days the reverse Colles fracture caused by the blow of the crank lever from the backfire of the motor, became commonplace. "Cowl" fractures of the patella are a recent innovation as a result of a change in body styling, while fractures of both tibia and the lower jaw have become common since the use of non-shatterable glass in windshields.

In this presentation we are dealing with a new "bumper" fracture of the midthird of the tibia. This fracture of both bones of the leg is so characteristic that an automobile accident as the causative agent can often be deduced from the typical appearances on the

the cortex usually on the anterior surface and often lying free from the rest of the fragments. The injury to the soft parts is usually severe and the fracture is often compound.

Other types of injuries will however occasionally produce the same characteristic fractures. In reviewing the literature of fractures of both bones of the leg we have carefully gone over the illustrations of the fractures presented and have occasionally found that

Fig. 1—A typical bumper fracture. Note severe comminution long linear fracture lines and diamond shaped fragment in center of comminution. Roentgenogram retouched.

roentgenogram alone. This the newer type of bumper fracture is characterized by a severe comminution and splintering of the bone with many larger and smaller fragments with long linear fracture lines running up and down the tibia and in the center of the comminution a diamond or pyramid shaped fragment out of

Fig. 2—Typical bumper fracture. Note loose pyramid shaped fragment from anterior cortex and comminution.

injuries in mines from coal cars, falling rock and the like, produce similar fractures. One can readily see that the mechanism of this fracture-producing violence is rather similar to the direct violence of the bumper of an automobile.

A few years ago Dr. N. A. Cary of Oakland, Calif. described a comminuted fracture of the head of the fibula and the external tuberosity of the tibia as a bumper fracture of the knee. An illustration in his paper depicts an automobile of the 1929 or earlier vintage. In the early days the bumper was placed much higher, but in the newer style with low center of gravity motors, the bumper is placed low and usually has a \sim shaped curve in the center. In the most popular of these low priced cars the bottom of the bumper stands normally only 13 inches from the ground, and then when the speeding automobile is suddenly stopped the front end is thrust downward several inches more, thus carrying the point of impact still lower, till it is centered exactly at the middle of the tibia in the average man.

The reduction of bumper fractures of the tibia offers the same problems as other fractures of both bones of the leg except that the severe comminution usually makes the reduction more difficult, and a greater variety of methods other than simple extension or manipulations and casts such as Kirschner wires, single or double pin technic, Boehler frames and the many other

mechanical means which are rapidly appearing on the horizon, are gaining vogue. Although this paper deals primarily with the healing of these fractures, there are several points in the reduction and fixation which have a great bearing on the ultimate healing, to which we would direct attention.

1 Excessive Manipulations to Obtain Anatomic Approximation—We have seen any number of bumper fractures in which there has been a satisfactory alignment but with only a mild overriding or displacement, necessitating from two to five manipulations to obtain complete approximation only to end in extremely delayed union. These repeated insults added to the original injury increase the local hyperemia with its decalcifying effects exhausts the regeneration power of the bones breaks up the early hematomas and fibrous framework of the future callus and is really putting too much of a strain on the reparative mechanism of the body to heal the fractures readily.

Fig. 3—Old type bumper fracture of knee described by Dr. Cary in 1932

traction overextension was little considered and seldom encountered. Most men felt that overextension could not occur and advised as much extension as could possibly be obtained by manual or mechanical means. Today, however, the advocates of the recent double pin traction, well leg traction or special wire traction apparatus almost universally warn against overextension.

3 Inadequate Immobilization—There are two factors of inadequate immobilization (1) incomplete immobilization and (2) immobilization for too short a period. Complete immobilization can best be secured by a well fitting plaster cast pins being used when necessary.

I believe with many others that the standardized time of fixation universally given for the healing time of fractures is fallacious. A fracture should be immobilized until clinically and roentgenologically union has taken place or until all hope of union has been forsaken and reconstructive surgery is decided on.

It is our experience that in the severely comminuted fracture, such as the bumper fracture of the tibia, the usual period of immobilization is altogether too short, the healing time is more apt to be sixteen or more weeks than six. This does not necessarily mean a greatly prolonged period of nonuse with its resultant stiffness of joints, atrophy of muscles and tissues plus impaired circulation. It is this prolonged nonuse that has con-

verted so many advocates to early massage, passive motion of joints and other forms of early manipulations that require splitting of casts, release of extension and interference with the proper immobilization. The advocates of early motion state that there is a right way to do this without causing motion in or displacing of the fragments, but how many surgeons or physical therapists are there on whom one can rely to do this? Such measures can only cause repeated traumatism to the early connective tissue, which is the framework of future callus, with recurring hyperemia of the part and promotion of decalcification of bones rather than calcification. Many authors state that slight motion within a fracture area promotes union. I believe this is unphysiologic and that union is obtained in spite of the motion. However, every orthopedic surgeon has seen fractures of long bones that have healed in the absence of all treatment, probably because the Lord is good.

Our experience leads us to agree with Watson Jones of Liverpool, that the greatest cause of nonunion in fractures of both bones of the leg is inadequate immobilization.

4 Compound Fractures—Our stand for the conservative treatment of compound fractures has been frequently presented before this and other medical associations and in the literature. Our experience with bumper fractures with direct and often severe compounding has not altered this view. We have treated them conservatively by first cleansing the wound and temporary immobilization, and then delaying reduction and all manipulations until the time arrives—usually

Fig. 4—Bumper fracture. Union after five months. Mild overriding and lateral displacement. Excellent alignment. no disability.

from five to eight days—when the danger of immediate infection is overcome. Our success has been uniformly good as in other compound fractures, and union has always been obtained in these cases.

The compounding of these fractures adds to the local hyperemia and inflammation and even if they are not infected they heal slower than simple fractures and therefore the rigid and active immobilization period to be described must necessarily be prolonged.

The most important purpose of this presentation is to emphasize the extreme slowness with which the bumper fracture unites. In our contacts with the various Cleveland hospitals and surgeons of northern Ohio, the story is always the same, these fractures are not healed after six to twelve weeks' immobilization no matter what method of treatment has been used. We encounter frequent instances of abandonment of fixation after ten to twelve weeks of immobilization with resultant deformity and nonunion already spoken of.

The literature fairly abounds in methods of reducing such fractures of the leg but little is said about the prognosis of these fractures the healing time or even as to what to do with them after the fracture is once reduced. Mention is sometimes made that fractures of the lower leg are slow to heal and that a convalescent brace is sometimes indicated, but the usual time of healing is given as from eight to ten weeks whereas in

our experience bumper fractures are infrequently united in this period of time. Our message is that bumper fractures of the leg are usually not united in less than sixteen weeks and often take much longer and that the treatment should be planned with this in mind and should not be abandoned under one year, unless solid union has been obtained before this.

Our plan of treatment is as follows:

1 Primary reduction and fixation is carried out by the elected method for about eight weeks.

2 After eight weeks the cast, if applied, is removed and a plaster mold of the leg is made and measure taken for a walking brace reaching to the thigh, with lock joints at the knee.

3 The plaster cast with walking iron or walking heel is reapplied.

By this time usually sufficient fibrosis has taken place within the fracture area so that the leg is no longer flail and there is no longer a danger of slipping of fragments. If this is not the case the cast without a walking splint is reapplied and the patient is compelled to use his crutches for from four to six weeks longer.

4 From the mold a model of the leg is made and a leather steel envelop brace with ring locks at the knee is constructed. This is form fitting and allows full weight bearing without any motion between fragments or any danger of angulation. The ordinary caliper brace is inefficient and does not completely immobilize the fragments.

By this weight bearing and active function the circulation of the extremity is improved, muscle tone is reestablished and bone production is stimulated. There is a gradual deposit of lime in the callus with increasing fixation of the fragments until solid union finally takes place.

The accompanying table shows the length of healing in bumper fractures actually treated by us. (We also have incomplete records of several hundred more treated at other hands in which the average healing time is about the same.)

Length of Healing in Bumper Fractures

| Time of Union in Months* | Number of Cases | |
|---------------------------------|-----------------|----------|
| | Closed | Compound |
| 1 | | |
| 2 | 17 | |
| 3 | 13 | 3 |
| 4 | 12 | 3 |
| 5 | 21 | 1 |
| 6 | 12 | 2 |
| 7 | 6 | 3 |
| 8 | 9 | 1 |
| 9 | 6 | 2 |
| 10 | 3 | 1 |
| 11 | 3 | |
| 12 | 7 | 1 |
| 13 | | |
| 14 | 1 | |
| 15 | | |
| Average healing time 6.2 months | | |

SUMMARY

1 The new bumper fractures of both bones of the leg are characterized by a severe comminution of the tibia with long linear fracture lines and a free diamond or pyramid shaped fragment out of the cortex.

2 These fractures are extremely slow in healing. The average healing time in a series of more than 100 cases was 6.2 months.

3 The treatment must be persistent or nonunion will result.

4 A practical method is employed of maintaining fixation of the fracture while allowing functional activity of the extremity.

1304 Hanna Building

ABSTRACT OF DISCUSSION

DR WILLIAM E. GALLIE, Toronto. The views of the authors may be sound, but I cannot agree with them on this subject of the newer methods of treatment. One might say that they are advocating that we cling to the older and well tried methods and be slow to take up such new fangled ideas as those advanced by Kirschner and Böhler. There is so much that is good however in these newer methods that I am sure that we would leave ourselves open to the criticism that we are showing our age if we were to condemn them. I believe that the Kirschner wire method of applying traction is the most valuable improvement in the treatment of fractures. The suggestion that these newer methods of treatment are too dangerous to be taught to our students applies equally well to treatment by manipulation and plaster, and as far as malunion and nonunion are concerned I think that it is the experience of most of us that the majority of such patients when ultimately sent to us for treatment have been treated according to the doctor's conception of it by just the plan that Drs. Stern and Papurt have outlined. The fact of the matter is that in most medical schools and hospitals the treatment of fractures is badly taught and we have only ourselves to blame that our students and interns get into trouble when confronted with difficult fractures. To test this out I would suggest that when the next serious compound fracture of the leg turns up we request the intern to carry out the whole treatment interfering only when the malpractice becomes too obvious. I fear that we shall not be pleased. This paper draws attention to the principles of treatment and clearly shows how failure to observe these principles leads to unfortunate results.

Fig. 5.—Typical bumper fracture. Over extension by double pin technic.

DR. PAUL B. MAGNUSON, Chicago The principles of treatment have not changed much for centuries. The first article that I can find on the subject was written about 462 B. C., and fractures were treated then in the same way—by extension and counterextension. The method of application of course depends on what is required in the individual case and what one has to work with at the time. Individual methods have been discussed many times to the exclusion of principles that are involved. When there is end bearing between the fragments, any simple method of traction or countertraction that will maintain reduction should be used. But when there is no end bearing and the fragments are constantly displaced by the muscle pull, traction and countertraction must take the place of end bearing of the fragments and some method must be devised to maintain them in position. The method chosen must depend on the circumstances under which the fracture must be treated. All fractures below the knee heal slowly, especially those involving both bones of the leg, owing probably to the poor circulation and poor nutrition. If the fracture involves the upper end of the tibia with a split into the joint, other methods of treatment must be considered, and in my experience bumper fractures are frequently complicated by such a split into the joint which slightly malaligns the joint. The object in these fractures is to obtain a good weight bearing line, and sometimes too much dependence cannot be placed on what is shown in the roentgenogram. Frequently the fibula will heal promptly and the tibia will not—why I do not know. With the increase in automobile accidents there has been a consequent increase in methods of treatment. Fractures nowadays come not alone to the man who is doing industrial surgery but to the man in general practice in rural districts because that is where most automobile accidents occur. The man in general practice therefore is the one who sees the fracture first, and the first reduction is a matter of importance so far as the end result is concerned.

DR. H. EARLE CONWELL, Fairfield, Ala. Fractures cannot be treated by one method in every instance. The treatment should be applicable to the fracture and not the fracture to the treatment. It has been customary in my clinic to classify all fractures, especially those of the leg, not only according to the bone injury but to the muscle and other soft structure damage as well. My associates and I classify our fractures as 1, 2, 3 and 4 plus. Treatment is then carried out according to the individual classification. The fracture of the tibia discussed by Drs. Stern and Papurt is usually of a severe type and in our clinic would fall under the classification of a 3 plus or a 3.5 plus leg injury, in which there is a tremendous amount of damage to the soft structures with comminution of the bone which may or may not be compound. This is the type of case in which skeletal traction by the Kirschner wire through the lower end of the tibia is definitely indicated. The patient should be hospitalized until some form of external fixation, preferably a plaster cast, can be applied. After the soft structures have healed sufficiently and this severe fracture has been reduced to a simple fracture, we apply our circular cast. Skeletal traction should always be removed as soon as possible and it is not always necessary that it be kept in the bone until firm union has taken place. I agree with the authors that there are dangers in skeletal fractures as in any other type of treatment, including the type of treatment that they have described. Fixation in the convalescent period of these fractures as the authors have emphasized is most important. The too early removal of fixation and too early weight bearing will frequently bring about angulation of the fragments and also delayed union in many cases. These cases are major problems and should not be handled by inefficient subordinates.

DR. LOUIS E. PAPURT, Cleveland I don't think that Dr. Stern meant to imply that he does not use pins or pin traction apparatus. We have Dr. Anderson's splint in our hospital and also the Macmillan splint. There are times when pins or wires must be used in selective cases but not indiscriminately. We have used them all but I don't think that they should be used as a routine. Bumper fractures are slow in healing. Treatment must be planned with that in mind and patients so informed. The treatment must be carried out until union results.

Clinical Notes, Suggestions and New Instruments

REVERSED COLLES FRACTURE SUCCESSFUL REDUCTION BY CLOSED METHOD

JOHN G. RAYMER, M.D., NORWICH, CONN.

Reversed Colles fracture occurs with relative infrequency. Its treatment therefore becomes a matter of importance to all who deal with fractures. Textbooks offer brief if any discussion of the subject and do not prepare the practitioner for the many

Fig 1—Before reduction May 14, 1935

difficulties which may attend the management of this type of injury. Webb and Sheinfeld¹ recently reviewed the subject and in concluding stated that "no cases of successful reduction of the described fracture by the closed method have been reported in the literature" and that "the fracture is therefore considered irreducible and operative reduction is advisable."

Fig 2—On discharge July 6, 1935

In order to help remedy the unwarranted neglect shown reversed Colles fracture in the literature, and to stimulate discussion as to its treatment, the following report of a successful closed reduction is submitted.

REPORT OF CASE

P. P., a white woman aged 38, seen May 14, 1935, within the past hour had fallen down a short flight of stairs and after being helped to arise had noticed at first only a numbness of her right wrist. On returning to work she noticed marked

¹ Webb, George, and Sheinfeld, William. Reversed Colles Fractures with Special Reference to Therapy. J. A. M. A. 104: 2324-2326 (June 29) 1935.

deformity of the wrist, which was at once reported. After immobilization of the wrist the patient was taken to the William W Backus Hospital, where roentgen examination revealed a reversed Colles fracture of the right wrist (fig 1).

Under general anesthesia the distal radial fragment was mobilized and by hyperflexion plus traction the fracture was reduced. Molded plaster splints were applied anteriorly and posteriorly with the hand in flexion, but the position was lost. Reduction was again secured, the splints being applied with the hand in a neutral position. This time the position, while improved, was unsatisfactory. A third reduction was made and the hand placed in an extended (cock-up) position and in adduction. Roentgen examination showed satisfactory position.

Ten days later the splints were temporarily removed and the skin given very light massage. At twenty days, position appearing perfect and with complete absence of pain passive motion was started, followed at twenty-four days by guarded active motion. At thirty days a light posterior wood splint was applied over the fracture, and at thirty-four days only a bandage around the wrist was required. This was worn for one week, and finally a leather strap was used for ten days.

July 6, roentgen examination showed the position satisfactory and healing progressing nicely (fig 2). Motion was excellent in all directions (estimated at 90 per cent), including supination. No pain was felt at the fracture site.

COMMENT

In this case the fracture line was situated sufficiently proximal to the joint so that effective manipulation and apposition of fragments could be secured and maintained. In determining the appropriate treatment for this type of fracture, the location of this line is an important deciding factor. The conclusion therefore is justified that certain cases of reversed Colles fracture can be reduced by the closed method and maintained throughout the necessary period of healing. It is suggested that the open reduction of such fractures be employed only when several attempts at closed reduction have failed.

40 Shetucket Street.

REVERSE COLLES FRACTURE—A PLEA FOR CLOSED REDUCTION

RALPH B. BETTMAN, M.D.

Associate Professor of Surgery, Rush Medical College

AND

WILLIAM J. TANNENBAUM, M.D.

CHICAGO

In the June 29 issue of THE JOURNAL Webb and Sheinfeld¹ stated that reverse Colles fractures are not rare, that these fractures are difficult to reduce, and that open operation is indicated. The tendency to abandon the conservative methods of closed reduction in fractures for immediate open reduction is, we think, a dangerous one as far as average practice is concerned and therefore we dislike to see an entire group branded as requiring operation. This is especially true when we try to recall our own experience with this type of fracture.

During an active service in traumatic surgery in the war and a much less active one since, it seems to us that we have seen many patients who had a Colles fracture in which the distal fragment was displaced anterior instead of dorsal to the bones of the forearm. Furthermore offhand it does not seem to us that we had much more trouble in the reduction of these fractures or that our treatment of them was much different from that used in the regular Colles fracture except that the hand was held straight or in more or less dorsal flexion depending on the case. At the time Webb and Sheinfeld's article appeared we had a patient with a reverse Colles fracture under treatment and it is this case which we report as an example of others we have seen in the past.

Miss H., aged 13 years, was thrown from a horse and in trying to break the fall stretched out her left arm. The impact came on the back of her hand just the reverse of the mechanism of the usual Colles fracture. We saw her an hour or so later and found the condition to be typical of that described

by Webb and Sheinfeld as the reverse Colles fracture (fig 1). Under a general anesthetic we reduced the fracture, controlled the reduction with a roentgenogram and placed the forearm and hand in a cast the hand being slightly dorsiflexed, the reverse of the classic Colles reduction position. The cast was immediately split to allow for swelling. A week later the top

Fig 1—This is a reversed Colles (fracture) in that the distal fragment is displaced toward the palmar rather than the dorsal surface of the wrist.

—Diagnosis of Dr. James Case

of the cast was removed to lighten it, in two weeks the arm was removed for gentle massage and limited motion and then replaced in the anterior half of the cast. The anterior half of the cast was shortened bit by bit and after four weeks there was no more splinting at all except for a leather wrist strap. Now three months later the arm is in perfect condition there is scarcely any deformity, the two wrists have to be studied together to be able to notice a difference, and the range of motion is practically full. The roentgenogram shows the excellent position of the fragment (fig 2).

We report this case to emphasize that

1. Reverse Colles fractures can be reduced and the reduction maintained without open operation.

2. We feel that an open operation is not indicated until after closed reduction has been tried.

Fig 2—Roentgenogram taken one month later. According to Dr. Case the fragments are in good position and the callus is satisfactory.

3. In the reverse Colles fracture the classic position of flexion must be discarded and a straight position or a position of dorsiflexion adopted as indicated by roentgenographic control of the position.

POLIOMYELITIS FOLLOWING VACCINATION AGAINST THIS DISEASE

J. P. LEAKE, MD

Medical Director U. S. Public Health Service
WASHINGTON, D. C.

During the past year in the United States, several thousand individuals, mostly children, have received subcutaneous and intracutaneous injections of treated poliomyelitis virus in the hope of acquiring immunity against the natural disease. The two different forms of treatment to which the virus was subjected were intended to render it innocuous when thus used as a vaccine. Through those responsible for the production of these vaccines, through several health officers and through others word has come to the United States Public Health Service of the development, at suggestive intervals following these injections, of cases of paralytic poliomyelitis with high fatality. Though possibly subject to some correction it is believed that the following statements represent closely the facts in each case.

1 A boy, aged 5 years, had his first symptoms of poliomyelitis six days after receiving the second dose of vaccine A in the left arm, the first dose having been given in the same arm twenty-seven days before the second. Paralysis began in the left arm the day after onset and death occurred after an illness of three days.

2 A girl, aged 21 months, received the second dose of vaccine A in the right arm twelve days after the first dose and the onset of poliomyelitis occurred six days after the second dose. Paralysis began in the right arm three days later and death occurred five days after the onset.

3 A boy, aged 4 years, had his onset of poliomyelitis eight days after the first dose of vaccine A in the left buttock and one day after the second dose at the same site. Paralysis began in his right leg two days later and is at present, after three months confined to that extremity, though there is hope of ultimate nearly complete recovery.

4 A girl, aged 8 years, had her onset of poliomyelitis eight days after the first dose of vaccine A in the left arm, and one day after the second dose in the same arm. Paralysis began in the arm two days later, and death occurred after an illness of three days.

5 A boy, aged 8 years, had his onset of poliomyelitis eight days after the first and only dose of vaccine A in the left arm. Paralysis began in the right arm two days later and remained as a deltoid paralysis at last accounts.

6 A boy, aged 5 years, had his onset of poliomyelitis nine days after the first and two days after the second dose of vaccine A in the arm. Arm paralysis began two days later, and death occurred after an illness of three days.

7 A boy, aged 10 years, had his onset of poliomyelitis ten days after the first dose of vaccine A in the left arm and three days after the second dose in the same arm. Paralysis began in the right arm the next day, and death occurred after an illness of three days.

8 A girl, aged 5 years, had her onset of poliomyelitis eleven days after the first dose of vaccine A in the right arm and four days after the second dose in the left arm. Paralysis began in the left arm four days later and was still present at last accounts.

9 A boy, aged 15 months, had his onset of poliomyelitis thirteen days after a dose of vaccine B, and developed general weakness four days later, which persisted at the last report.

10 A boy, aged 5 months, had his onset of poliomyelitis fourteen days after a dose of vaccine B and paralysis was first

noticed nine days later. This paralysis persists at the last report.

11 A girl, aged 6 years, had her onset of poliomyelitis fourteen days after the first, and seven days after the second, dose of vaccine A in the arm. Paralysis began in the left arm three days later, and complete recovery was questionable at the last report.

12 A youth, aged 20 years, had his onset of poliomyelitis fourteen days after the first and only dose of vaccine B in the arm. Paralysis began in the arm two days later, and death occurred after an illness of four days. From this case poliomyelitis was transmitted to monkeys by Dr. Kessel.

Paralytic poliomyelitis was not epidemic in any of the localities at the time of the occurrence of these cases if these cases themselves are not included in the count. During the heaviest incidence of poliomyelitis in the community with the highest reported incidence, the expectation of paralytic poliomyelitis among those vaccinated within three weeks following vaccination, judging by its occurrence by age groups in the community at large, was less than one tenth of a case, yet a case occurred. At the other periods and in the other localities cited the chance of a case occurring among the vaccinated was much less, yet in each instance cases occurred. The likelihood of the whole series of cases having occurred through natural causes is extremely small. In none of the cases was exposure to infection outside its own area known to be of special significance.

It is believed that to many physicians this series of cases, following by intervals of from six to fourteen days the injection of one or the other of two different vaccines, renders undesirable the further use of poliomyelitis virus for human vaccination at present.

In every case in which the sequence is known, the level of the spinal cord first affected corresponded to the extremity in which the injection was made, paralysis beginning either in the same limb or in the contralateral limb. This is strong support to other evidence that the virus of poliomyelitis is transmitted along nerve fibers since neither blood nor lymph streams would afford direct access from one extremity to the corresponding cord level. The remarkably high fatality in this series of cases was perhaps due to the part of the cord primarily infected being close to the nuclei corresponding to the muscles of respiration. The possibility is to be considered that a strain of poliomyelitis that has been subjected to prolonged monkey passage, with rather short incubation periods, is unusually virulent to man when administered by the subcutaneous or intracutaneous route. Though in a few of these cases it is possible or even probable that there was another intercurrent illness in addition to poliomyelitis, in general the paralytic symptoms were such as would be expected in poliomyelitis naturally acquired.

In forming a judgment as to the applicability of a poliomyelitis vaccine the not inconsiderable local and general reactions following its use need to be taken into account.¹ It is also noteworthy that the appearance of neutralizing antibodies in the blood after the injection of poliomyelitis virus is very uncertain evidence of parallel immunity to the natural disease.²

Although any one of these cases may have been entirely unconnected with the vaccine, the implication of the series as a whole is clear.

RADIOTHERAPY

(ROENTGEN RAYS, RADIUM)

ARTHUR U DESJARDINS, MD

ROCHESTER, MINN

(Concluded from page 2071)

Mode of Action—The rate of resolution of acute inflammatory lesions after irradiation corresponds to the rate at which normal leukocytes, notably the lymphocytes and polymorphonuclear cells, are known to be influenced by exposure to roentgen rays or radium. Moreover, the fact that a single, small dose usually suffices to induce resolution of acute inflammation also suggests that the main factor in the action of the rays on such lesions consists in destruction of infiltrating leukocytes. A considerable body of experimental and clinical evidence supports this view. Variation in the degree of leukocytic infiltration in different inflammatory processes may well account for differences in the effectiveness of irradiation at different stages. Destruction of leukocytes infiltrating an acute inflammatory lesion might, on superficial consideration, be regarded as necessarily deleterious. Prolonged experience, however, has failed to yield the slightest evidence of harmful effect, except when excessively large doses of rays have been used. On the whole, it seems most likely that destruction of infiltrating leukocytes liberates the antibodies and other protective substances previously elaborated within the cells and thus makes these substances more readily available for defensive purposes than when they were in the intact cells.

Chronic—Chronic inflammations of different kinds also are amenable to radiotherapy. Tuberculous adenitis and peritonitis, actinomycosis and blastomycosis may be mentioned as examples. In dealing with chronic inflammation, single small doses of radium or roentgen rays no longer suffice. The dose must be larger than in the case of acute inflammation although distinctly smaller than the maximal dose required in the treatment of tumors. Whereas in acute inflammations the dose may vary between 25 and 50 per cent of the limit of tolerance of the skin, in chronic inflammations the most effective dose varies between 50 and 80 per cent of the limit of tolerance of the skin. Still more important, however, cure or maximal benefit requires that irradiation be repeated a number of times at intervals of three or four weeks, smaller doses may be repeated at shorter intervals. Complete resolution of chronic inflammatory conditions is slow and can be obtained only by repeated treatment. This is especially true of tuberculous processes, in which the most effective treatment seems to be periodic exposure of the affected region to roentgen rays, combined with exposure of the entire body to gradually increasing doses of ultraviolet rays.

Mode of Action The effect of radiotherapy in chronic inflammations appears to depend mainly on two factors, on the one hand the degree of leukocytic infiltration, and, on the other, the proportion of connective tissue and of degenerative products such as caseous material and calcium. The relative proportion

of these two factors seems largely to account for variation in the time required to bring such lesions under control.

Miscellaneous Conditions—Hyperplasia of the Thymus Gland. Hyperplastic increase in the size of the thymus gland is not uncommon among children. This may be associated with cough, dyspnea and stridor, but the coincidence of such symptoms and thymic hyperplasia does not mean that the symptoms are the result of an increase in size of the gland. In many if not in most cases the respiratory symptoms and the enlargement of the thymus probably result from some nutritional or toxic disturbance. If the cause of the disturbance can be found and eliminated, the symptoms promptly disappear. If the etiologic factors cannot be discovered treatment with roentgen rays provides a most satisfactory means of reducing the volume of the enlarged thymus gland, and this is often accompanied by relief from respiratory symptoms. A single exposure to a moderate dose of roentgen rays may be counted on to induce rapid shrinkage of the hyperplastic gland but if subsequent regeneration and the possibility of renewed enlargement are to be prevented the region of the thymus should be irradiated two or three times at intervals of two or three weeks.

Hyperthyroidism There can be no doubt that cure or substantial improvement can be obtained by radiotherapy in a certain proportion of cases but a larger proportion of patients can be cured with greater certainty by expert medical and surgical treatment. In other words, radiotherapy for hyperthyroidism is attended by a greater measure of uncertainty than skilled medical and surgical treatment. If the symptoms are not severe and the urgency of therapeutic measures is not too great, roentgen irradiation may be tried. Such a trial involves repeated exposure of the thyroid (and thymic) regions within three or four months. Should such a trial fail to result in complete relief further radiotherapy should be given up. Regardless of the method of treatment systematic and careful study of all clinical and metabolic features should be made by a qualified physician.

Leukemia In acute leukemia exposure to roentgen rays or radium is seldom followed by perceptible improvement and experienced radiologists usually do not encourage such treatment. In the subacute form cautious treatment and in the chronic form thorough treatment yield more or less marked improvement for periods varying from months to several years. Usually the treatment must be repeated from time to time depending on the numerical behavior of the leukocytes and on the tendency of the spleen or lymph nodes to enlarge. Effective treatment can be given with roentgen rays or radium. At the outset, and when extensive areas require irradiation roentgen rays are preferable.

In myeloid leukemia the rays are directed first to the spleen, and then, if this is not sufficient to reduce the number of leukocytes approximately to the normal level the mediastinum and long bones also may be irradiated. When the spleen is large, the surface of the abdomen corresponding to that organ may be divided into a number of fields approximately 10 cm square and each field should be exposed to a moderate dose of roentgen rays. If radium is used to irradiate the enlarged spleen, a large pack is required. The effect of treatment on the leukocytes should be followed closely by daily or frequent blood counts. When the number of leukocytes diminishes rapidly, the number of fields irradiated each day should be correspondingly

reduced, otherwise, an excessive leukopenia may result. An abnormally small number of erythrocytes at the outset need not be regarded as a contraindication, under treatment the number of these cells tends to increase as the number of leukocytes diminishes. After a patient has been treated a number of times at intervals of months, the effectiveness of treatment tends to diminish, but this varies considerably from patient to patient. If the patient cooperates faithfully, the disease may often be kept under control for prolonged periods, sometimes for many years.

In lymphoid leukemia the treatment is directed first to the main groups of lymph nodes in the neck, axillae and groins, as well as to the mediastinal and retroperitoneal lymph nodes. If, by the time these several regions have been irradiated, the number of leukocytes has not diminished sufficiently, additional treatment to the shaft of the major long bones may have to be given.

The action of roentgen rays on leukemic hyperplasia of the spleen, lymph nodes and other structures, including the skin, is to destroy leukocytes (chiefly lymphocytes and polynuclear cells) or to cause such cells to pass through their life cycle so rapidly as to constitute virtual destruction. Leukemic infiltrations of the skin, with or without pruritus generally subside as the number of leukocytes decreases and as the other clinical manifestations improve. After a time which varies from patient to patient and which apparently depends on the relative acuteness or chronicity of the disease, radiotherapy may become less effective. Usually this means that the disease is approaching its terminal phase. This phase may be accompanied by a tendency to hemorrhage or by increasing weakness and death, sometimes without fresh hyperplasia of the spleen or lymphoid structures.

Hodgkin's Disease, Lymphogranulomatosis, Lymphoblastoma — (See Tumors Derived from Lymphoid Cells.)

Benign Tumors — **Giant-Cell Tumor of Bone** There is evidence that, in most cases, the giant-cell tumor of bone is a chronic inflammatory process and is therefore essentially benign. The reaction of such tumors often differs from that of malignant processes in general. After irradiation, all malignant tumors retrogress to different degrees or do not undergo any perceptible change. Two or three weeks after irradiation, in many cases, a giant-cell tumor begins to swell, and the swelling is accompanied by redness, pain and tenderness. To the patient as well as to the uninitiated physician such manifestations may give the impression that irradiation has increased the activity of the tumor, and a hasty amputation may be undertaken. If not disturbed, this swelling, redness and pain begin to subside after a week or ten days and may gradually disappear. New bone is slowly deposited in the tumor, which, in the course of time, is replaced by solid bone.

Fibromyoma Uteri In the absence of contraindications, radiotherapy is an excellent method of treatment because it avoids operation with its attendant hospitalization, disability and possible mortality, which, though small when the operation is performed by an experienced surgeon, can hardly be called negligible. Roentgen rays act primarily on the ovaries and abolish menstrual function in from three to eight weeks. This is followed by cessation of bleeding and a gradual regression of the uterine tumors, with corresponding relief from pain, discomfort and other symptoms. But one course of treatment, consisting of two or three daily exposures to roentgen rays of short wavelength,

is sufficient in all but a small proportion of cases, in which the treatment may have to be repeated once after an interval of three months. If the treatment is given within one week after a menstrual period, menstruation is not likely to recur. If given later, the patient may menstruate once or even twice more, and the menstrual bleeding may be more abundant than usual but will then cease permanently. Roentgen rays are preferable to the intra-uterine use of radium, except when the fibromyomas are definitely submucous.

Classification of Tumors from Standpoint of Radiosensitiveness

| Radiosensitive Tumors | |
|--|---|
| Group 1 | Lymphoblastoma { Lymphosarcoma Hodgkin's disease |
| | Lympho-epithelioma (Ewing) or endothelial myeloma (Kodansky) of bone |
| Group 2 | Embryonal carcinoma (seminoma of testis) (spermatogonial cells) |
| | Embryonal carcinoma of ovary (follicular epithelium) Embryonal carcinoma of kidney (Wilms tumor) |
| Group 3 | Giant cell tumor of bone |
| | Multiple myeloma of bone |
| | Basal cell epithelioma |
| | Transitional cell epithelioma |
| | Mucinous carcinoma of intestinal tract (mucous secreting epithelial cells) |
| Hemangioma | |
| Hemangio-endothelioma | |
| Moderately Radiosensitive Tumors | |
| Group 1 | Carcinoma of uterine cervix |
| | Carcinoma (not adenocarcinoma) of thyroid gland |
| Group 2 | Epithelioma of tonsil and pharynx |
| | Carcinoma of breast |
| | Epithelioma of bronchus |
| | Epithelioma of lip and eyelids |
| | Epithelioma of mouth and tongue |
| | Epithelioma (squamous cell) of skin |
| Carcinoma of rectum | |
| Chondrosarcoma of bone | |
| Radioresistant Tumors | |
| Fibromyoma (uterus) direct irradiation | |
| Fibrosarcoma | |
| Carcinoma of esophagus and stomach | |
| Adenocarcinoma anywhere with possible exception of uterus (cervix or fundus) and thyroid gland | |
| Mixed tumor of parotid gland | |
| Hypernephroma | |
| Sarcoma of bone osteogenic | |
| Melanoblastoma and nonmelanotic melanoblastoma of skin | |
| True teratoma | |
| Neurofibroma | |
| Fibroma | |
| Chondroma | |
| Lipoma | |
| Myxoma | |
| Myxosarcoma | |

The amenorrhea resulting from radiotherapy is exactly the same as that of the natural menopause, except that it comes on more rapidly. Its subsequent course is identical to the natural process, all legends to the contrary notwithstanding. The size of the tumor or of the tumefied uterus per se is not a contraindication for radiotherapy. On the contrary, excessive bleeding with anemia demanding urgent relief, the wish to avoid amenorrhea by a woman who still may have and desire children, the presence of pedunculated or calcified fibromyomas, and an incarcerated uterus require surgical operation in preference to radiotherapy. The transformation of fibromyoma into sarcoma or carcinoma by irradiation has never been established. It is probable that, in the cases reported, the uterine tumor was a sarcoma or carcinoma from the start.

Malignant Tumors — **General Considerations** The radiosensitiveness of tumors corresponds closely to the sensitiveness of the cells of which they are chiefly composed. This fundamental law enables the experienced radiologist to utilize irradiation not only to treat but sometimes to distinguish certain neoplasms from others.

Naturally, the diagnostic value of such a therapeutic test is greatest in neoplasms derived from the more sensitive varieties of cell, the information thus derived may sometimes be as valuable as the microscopic observations of the pathologist. From the standpoint of radiosensitivity, tumors may be classified as in the accompanying tabulation.

Such knowledge has made it possible to differentiate certain varieties of tumors, such as lympho-epithelioma and Ewing's endothelial myeloma of bone, from other neoplasms with which they had previously been confounded. In tumors of the mediastinum, for example, roentgen irradiation almost always permits one to establish in a short time a clear distinction between a lymphoid tumor and an aneurysm. Moreover, when the reaction of roentgen rays is correlated with the clinical features, the usefulness of the therapeutic test may be considerably extended.

The most important effect of irradiation is to destroy those cells in a tumor which are most radiosensitive. In malignant processes characterized largely or wholly by lymphoid hyperplasia, the regression of hyperplastically enlarged lymph nodes is quite rapid, in other varieties of tumor, regression may be slow and less pronounced, whereas, in tumors composed of cells that are not sensitive to irradiation, perceptible regression may not occur even after large doses. Besides the direct destruction of cells, however, certain other factors play a part in the effect of radiotherapy on malignant growths. The cells which are destroyed by irradiation are replaced by connective tissue, and this has given rise to the notion that roentgen rays "stimulate" the formation of connective tissue. If the dose of rays exceeds the tolerance of the connective tissue cells present in a tumor, a proportion of these cells degenerate, and this leads to further increase in connective tissue. The action of the rays on the blood vessels of a tumor, with thickening or obliteration of the vessels and resulting diminution in the blood supply of the growth, also plays an important part in the effect of irradiation.

The impression that exposure of a tumor to roentgen rays may cause it to grow more rapidly arises from a misconception. After a period of relative quiescence or complete arrest following one or more courses of radium or roentgen treatment, the tumor tends to recover its original rate of growth. For a time it may actually grow more rapidly than before. This, however, is exceptional and is only a transient phase of the process. In many tumors, on the contrary, subsequent growth tends to be slower than before irradiation. Moreover, many new growths do not develop at a uniform rate, without reference to irradiation. If such a tumor should have passed from a phase of relative quiescence into a phase of greater activity, and if it should recently have been exposed to roentgen rays, the inexperienced observer might draw the erroneous conclusion that the increased activity was due to the action of the rays. The extensive experience of the most competent observers indicates that exposure of a tumor to roentgen rays or radium either causes inhibition of growth or remains without effect.

Tumors Derived from Lymphoid Cells (Hodgkin's Disease, Lymphogranulomatosis, Lymphosarcoma, Lymphoblastoma)—During recent years, pathologists have tended to regard these diseases as phases of the same condition and to designate them by the collective term "lymphoblastoma." Strictly speaking the suffix "oma" indicates a tumor, and it can literally apply only

to lymphosarcoma, the fatal tendency of both conditions, however, has led many to consider them essentially neoplastic in character. Substantial evidence exists that the immediate cause of Hodgkin's disease and lymphosarcoma is long-continued infection of any kind. From a clinical point of view, and sometimes from a pathologic point of view also, the two conditions affect the lymphoid structures in much the same way, and often a purely clinical distinction cannot be made. Lymphosarcoma tends to metastasize more widely than Hodgkin's disease, but this is not often evident before death or, at least, before the late stages of the process. An important reason for considering the two conditions at the same time is that their treatment and their reaction to treatment are essentially identical.

In some cases the disease first manifests itself in the cervical lymph nodes and thence extends to the mediastinal, axillary and other nodes. In other cases the condition originates in the abdominal nodes and extends to the inguinal, mediastinal and other nodes. A few cases are encountered in which the disease primarily affects the stomach or the intestine. Bones may become involved either by pressure from adjacent hyperplastic lymph nodes or by invasion of the bone marrow. Nearly always, the nodes in which the disease first manifests itself are in anatomic relation to a region in which chronic infection has been present.

Tumors of this kind are exceptionally radiosensitive and retrogress rapidly under treatment. Many radiologists irradiate only regions in which enlarged lymph nodes are obvious. Usually it is preferable to give the patient from two to four courses of partial or general irradiation directed to the main lymphoid regions: the neck, axillae, groins, and mediastinal and retroperitoneal spaces. Irradiation of the ovaries of women less than 40 years of age should be avoided as much as possible. For general irradiation, a moderate dose of rays of medium wavelength usually yields the best results if all factors of the situation are taken into account. The condition and reaction of the blood (cellular elements) should be closely watched.

The immediate results of radiotherapy are often little short of miraculous. Patients with marked dyspnea, cough and obstructive engorgement of superficial veins may derive remarkable benefit in a few days. If treated thoroughly but carefully, the lymphadenopathy should largely or completely disappear in many cases, and meticulous periodic examination and occasional treatment as fresh hyperplasia of the lymph nodes occurs may enable the patient to remain well for months or, indeed, for several years. In a small proportion of cases lymphosarcoma reacts even more promptly than Hodgkin's disease, but in the average case the difference is hardly sufficient to constitute a distinctive feature. In lymphosarcoma, even metastatic infiltration within the skull and its associated symptoms may be made to disappear. Unfortunately, such metastasis indicates advanced disease, and improvement in the cerebral condition may soon be followed by fatal complications in some other part of the body.

Lympho-Epithelioma—Tumors of this kind usually arise around the nasopharynx, but they sometimes arise in other parts of the body also. They present a general microscopic appearance of epithelioma and are regarded as such by most pathologists, but their possible lymphoid origin and essential nature are shown by the fact that they are much more radiosensitive than

ordinary epithelial neoplasms. Growths of this kind often undergo marked and rapid regression after thorough treatment, and permanent cure has been recorded in some cases.

Tumors of the Testis—The term "teratoma," so commonly used to designate all tumors of the testis, is unfortunate because it tends to create confusion. While it may be true, as Ewing contends, that all these tumors are teratomas with one-sided development, it would seem desirable from clinical and therapeutic points of view to distinguish these varieties of testicular neoplasm from the true teratoma, which is relatively benign. The most common tumor of the testis, occurring in from 65 to 70 per cent of cases, is the embryonal carcinoma, derived from the basal or spermatogonial epithelium of the seminal tubules. It is often mistaken for sarcoma. Another, less common neoplasm of the testis is the mixed, or teratoid tumor which represents from 25 to 30 per cent of all tumors of this organ. Derived from all three embryonic layers it is composed of a rather indiscriminate mixture of embryonal tissues and, therefore, has a heterogeneous appearance. The true teratoma and a few other rare neoplasms make up the remainder of the tumors that affect the testis.

In the embryonal carcinoma or in the mixed or teratoid tumor, metastasis usually first affects the para-aortic lymph nodes in the region of the celiac axis where it may be confined for a long time. Later sometimes much later, metastatic elements may extend through the thoracic duct to the sentinel nodes in the left supraclavicular space to the mediastinum, and still later to the lungs, brain and other parts of the body. When metastasis to the retroperitoneal nodes has not occurred, orchidectomy may yield a permanent cure in a small percentage of cases, the difficulty of being certain about metastasis probably accounts for the large proportion of surgical failures. Metastasis to the para-aortic nodes occurs much earlier than is generally suspected. Even when such metastasis is not apparent, removal of the affected testis should be followed as soon as possible by thorough irradiation of the entire abdomen (from front and back and from both sides), and this procedure should be repeated once or twice at suitable intervals. Better still however, orchidectomy should be preceded by one or two thorough courses of roentgen irradiation directed to the primary tumor as well as to the abdomen, and an interval of about six weeks should be allowed to intervene between irradiation and operation. When metastasis has already occurred surgical removal of the primary growth is of no avail, but it may sometimes be advisable to relieve pain caused by the dragging weight of a bulky tumor.

In cases of embryonal carcinoma, well planned treatment with roentgen rays induces marked and rapid regression of the primary growth as well as of its metastatic deposits. The regression of mixed or teratoid tumors varies, sometimes it is rapid and pronounced, the growth sometimes practically disappearing, and sometimes it is slower and only partial. The rapidity and degree of regression of such growths apparently depend on the proportion of spermatogonial epithelium entering into their composition. The greater the proportion of such radiosensitive epithelium, the more rapid and the more complete the regression. Unfortunately few neoplasms of this kind disappear completely and permanently, but complete and sometimes permanent regression of an embryonal carcinoma is not so rare. In the latter variety a complete cure

may result from thorough treatment before metastasis has extended beyond the para-aortic nodes. But even though, in the majority of cases, more or less extensive metastasis may prevent permanent cure, adequate treatment may often lead to marked and prolonged improvement.

Tumors of the Ovary—Of the tumors that affect the ovary the colloid carcinoma is perhaps the most radio-sensitive, but none of them respond so rapidly or so favorably to roentgen rays as do epithelial tumors of the testis. Nevertheless, many patients derive sufficient benefit to make treatment worth while. Radiotherapy is not a substitute for surgery in operable cases but may be used before or after operation, or both, to prevent or delay recurrence and metastasis. When operation cannot be considered, thorough irradiation of the pelvis and abdomen may often result in substantial, temporary improvement.

Tumors of the Nose, Nasopharynx and Pharynx—Moderate irradiation with radium or roentgen rays may sometimes usefully supplement other measures or may make such measures unnecessary. If the quantity of radium available is not sufficient for effective external irradiation, roentgen treatment is preferable because it avoids the unpleasantness or discomfort of intra-oral application of radium.

Some tumors of the nose, nasopharynx or pharynx, such as lymphosarcoma, lympho-epithelioma and those of Hodgkin's disease are quite radiosensitive, whereas others, such as squamous cell epitheliomas, may offer a considerable degree of resistance to irradiation. Radium can often be implanted throughout such growths, but this should be supplemented by external irradiation with radium or roentgen rays. In some institutions the growth is first destroyed by electro-coagulation, radium needles or radon seeds are then implanted throughout the margins and base of the destroyed mass of tissue and these procedures are supplemented by external irradiation. This also applies to tumors of the tonsil. As for simple lymphoid hyperplasia of the tonsils, treatment with roentgen rays is simpler than with radium. Surgical treatment in conjunction with or exclusive of, irradiation may sometimes be advisable.

Carcinoma of the Thyroid Gland—Like adenocarcinoma of any other organ, adenocarcinoma of the thyroid gland must be classified among the radio-resistant tumors. Ordinary carcinoma of the gland, on the contrary, is more susceptible to roentgen rays, and next to embryonal carcinoma of the testis and carcinoma of the uterine cervix, is the most sensitive of all carcinomas. Why this should be so has not yet been made clear, but the fact is undeniable. Usually such a tumor is discovered by the pathologist in the course of a microscopic inspection of thyroid tissue excised by the surgeon on the clinical assumption of simple adenoma of the gland. In any event, thorough roentgen irradiation of a primarily inoperable tumor of this variety, and even of metastatic deposits in the mediastinum, skull or elsewhere, often causes the neoplastic elements to retrogress or disappear. Although such retrogression may be temporarily complete, it is almost never permanent. The tumor may disappear and the patient may be well for one or two years, or even longer, but it may generally be counted on to reappear sooner or later. Nevertheless, radiotherapy is distinctly worth while as a means of furnishing temporary and sometimes prolonged relief from symptoms.

Carcinoma of the Breast—The consensus still is that the best treatment for mammary carcinoma in the operable stage is radical amputation of the breast. From present indications it appears possible that this opinion may subsequently be modified to some extent, but the time for any general departure from present methods has not yet come. In most institutions the method in vogue is radical amputation of the breast, followed, as soon as the condition of the patient allows but generally one or two weeks later, by thorough irradiation of the affected side of the thorax in the earliest cases, or of the entire thorax in the case of large primary tumors, with or without extension to the tributary lymph nodes. The advisability of preoperative and postoperative irradiation is now being considered and tested.

For thoracic irradiation, some prefer rays of medium wavelength while others employ rays of short wavelength. The quality of rays must be governed largely by the method of irradiation. When the patient is irradiated only after operation, the treatment should be repeated once or twice at intervals of from three to six weeks, but to repeat such treatment indefinitely seems excessive and useless. If two or three thorough courses of postoperative irradiation should fail to prevent recurrence, it is not likely that indefinite repetition can be successful. Moreover, if the latter procedure is followed and carcinoma should recur in spite of it, the recurring lesions are not likely to be influenced favorably by further exposure to the rays. The results of a sound operation combined with sound postoperative irradiation appear superior to those of operation alone, but the evidence of such superiority is not so conclusive as might be desired. The reason is that few institutions or surgeons in private practice have undertaken a fair and thorough test.

If undertaken at all, preoperative irradiation should be thorough. Radium needles or radon seeds, incorporating sufficient filtration to remove all the beta rays, should be implanted throughout and around the primary growth, and this procedure should be supplemented by converging, or tangential, roentgen irradiation from without. If the primary growth is too large for effective implantation of radium or radon, several beams of roentgen rays may be made to converge on the breast. The essential point is that the largest possible dose (total dose) of rays should be concentrated on the area occupied by the tumor. The axillary space also should be thoroughly irradiated.

When metastasis to the axillary nodes, or to these and to the supraclavicular nodes, has occurred, however, the surgical indications are no longer clear. Indeed, a growing body of opinion favors abstention from surgical procedures and advocates radiotherapy. Moreover, one point seems increasingly clear, this is that, if a mammary carcinoma has once been pronounced inoperable, it should usually be thenceforth regarded as inoperable, regardless of the degree of improvement that may follow radiotherapy. Occasionally for special reasons this rule may be disregarded, but in most cases it should stand. The rule is of the greatest significance in cases of carcinoma affecting the breast during pregnancy and during the period of lactation. If under these circumstances the rule is disregarded because the primary growth has retrogressed and has become freely movable and because amputation of the breast then seems technically feasible, rapid and widespread extension of the malignant process is prone to occur.

When mammary carcinoma is definitely inoperable, radiotherapy may still accomplish much for the patient. Even when ulceration threatens or has actually occurred, thorough roentgenization can often be counted on to cause the potential or actual ulcer to heal and the primary and secondary malignant elements to recede and sometimes to disappear. Pain in the back, radiating to one or both lower extremities and indicating metastasis to the lumbar portion of the spine or to paravertebral lymph nodes in the same region (the pain being caused by pressure on branches of the lumbosacral plexus), can usually be relieved by exposure of the lower thoracic and lumbar regions to roentgen rays through parallel fields on each side of the median line, the rays being directed so as to converge on the vertebrae and tissues immediately anterior to them.

When carcinoma, originally affecting the breast, recurs in the same or in another region, well planned radiotherapy may still control the lesions for months or years and may relieve pain for prolonged periods. The same is true of metastasis to certain regions, such as the lumbar portion of the spine or the paravertebral lumbar lymph nodes, causing pain in the back radiating to one or both lower extremities.

Carcinoma of the Uterus—The favorable effect of combined radium and roentgen treatment on carcinoma of the uterine cervix is well known. It is not certain whether such excellent results depend chiefly on the exceptional radiosensitiveness of cancer in this situation or on the comparative facility with which, in early cases at least, a cancericidal dose can be delivered to every portion of the cervix. It is certain, however, that much of the favorable influence of the treatment must be credited to radium and only a minor part to roentgen rays. The purpose of external roentgenization is to supplement the intra-uterine, cervical and vaginal applications of radium and to increase the total dose of radiation reaching the cancer cells, especially outlying cells in the broad ligaments and pelvic lymphatics. The proof that such supplementary external irradiation plays a certain part in the final result is to be found in the fact that, in certain institutions in which radium is not available, roentgen irradiation yields results which, though not comparable to those of radium treatment alone, are distinctly worth while. Also, other tests have shown that the combined treatment is better than radium irradiation alone. Although a few surgeons still advocate hysterectomy for carcinoma of the cervix, the number of those who no longer advise operation in such cases is steadily increasing. The reason for this gradual shift of surgical opinion is that the results of radiotherapy and surgery are approximately equal, but the former has the advantage of avoiding the mortality of the latter.

With reference to carcinoma of the body of the uterus the situation is somewhat different. Here surgical intervention (hysterectomy) is still advocated in preference to radiotherapy whenever the malignant situation has not passed beyond the bounds of operability. Radiotherapy is usually reserved for the inoperable cases, the aim being to bring about as much temporary improvement as possible. During the last few years, however, medical opinion has shown a tendency to shift toward radiotherapy.

Carcinoma of the Bronchus—Sometimes external, converging irradiation with roentgen rays may usefully be supplemented by implanting radon seeds directly into an intrabronchial growth (through a bronchoscope), but

in most cases such a procedure is difficult. Instead, that portion of the growth which can be seen through the bronchoscope can be electrocoagulated, and the entire region can be exposed to several converging beams of roentgen rays.

Carcinoma of the Esophagus—Radium and roentgen rays can sometimes be effectively combined, but the results heretofore reported have not been striking. Highly filtered radium introduced into the affected portion of the esophagus, supplemented by a large total dose of roentgen rays from without, might lead to some improvement in results, but the natural resistance of such lesions to irradiation, the difficulty of administering adequate irradiation to every part of the growth, and the tendency to mediastinal infection will probably continue to limit the value of treatment.

Carcinoma of Gastro-Intestinal Tract—Generally speaking, carcinoma of the stomach is comparatively resistant to irradiation. A certain proportion of patients suffering from such lesions may derive moderate improvement for a time, but such improvement is seldom great and seldom lasts more than a few months. Moreover, when the general condition of the patient is bad, radiotherapy sufficient to influence distinctly the malignant process is likely to cause further deterioration and weaken the already strained power of resistance, particularly if the tumor has invaded the liver. No possible good can come from exposure to roentgen rays under such circumstances. In carcinoma of the large bowel and especially of the rectum, radiotherapy may be worth while. The symptoms may be considerably or entirely relieved for a time, but permanent cure cannot be expected. In carcinoma of the rectum or the rectosigmoid portion of the colon, radium applied directly to the growth and roentgen irradiation from without are often followed by substantial benefit, which may continue for months. In other cases irradiation may inhibit the growth of the malignant process to some extent but for only a short time. Therefore, radiotherapy should be used before or after operation in operable cases or should be reserved for inoperable cases.

Tumors of the Kidney—Most renal tumors in adults cannot be regarded as radiosensitive, but embryonal carcinomas in adults or in children are quite radiosensitive. Surgical removal alone seldom results in cure. The effect of radiotherapy on hypernephroma and primary carcinoma in the adult is usually slight and transient, but on embryonal tumors the effect of thorough irradiation is to cause rapid regression, sometimes to the point of complete clinical regression. Unfortunately, such regression is not lasting, within a relatively short time the tumor again begins to grow and a fatal outcome is the rule. Recently, the idea of thorough irradiation to the point of maximal regression, followed by surgical removal of the affected kidney and residue of the tumor, has been advanced and is now being tested.

Tumors of the Skin—Basal-cell epithelioma is quite amenable to roentgen treatment, a large percentage of such lesions can be cured permanently in this manner. Massive doses of rays of long or medium wavelength, or both combined, are preferable, but fractional doses at relatively short intervals may be nearly as effective if the total dose within a given time is sufficient. Treatment with small doses at random should never be undertaken. By massive single doses is meant from two to ten times an erythema dose at one sitting. One half of this dose may be given with unfiltered roentgen

rays generated at a potential between 80 and 100 peak kilovolts, and the other half with rays filtered through 3 or 4 mm of aluminum and generated at a potential between 130 and 140 peak kilovolts. Such a massive dose can be given with safety to an area less than about 2 cm in diameter, but should never be given to an area larger than this. If the lesion is larger, an erythema dose cannot be greatly exceeded with safety.

If operable, squamous-cell epithelioma should preferably be dealt with by thorough and wide surgical excision, followed by two or three postoperative courses of roentgen irradiation at intervals depending on the dose employed. To undertake to treat such lesions with roentgen rays alone is to risk doing grave injustice to the patient and to assume too great a responsibility. It is true that cure may be effected in this way in some cases if early and well conducted irradiation is employed, but too often a satisfactory initial result is spoiled by renewed malignant activity or metastasis. Melanoblastoma is one of the most resistant of neoplasms. When the primary lesion is small, exposure at one session to several times an erythema dose of filtered rays and to an equal quantity of unfiltered rays may cause the growth to disappear, and the patients remain well. Certainly the method is superior to ordinary surgical excision, but thorough destruction by surgical diathermy may be as effective as roentgen rays. When metastasis has occurred, however, roentgen treatment is generally useless.

Adenocarcinoma—For some reason, this variety of epithelial cell tumor, regardless of the organ or structure in which it originates, has a higher degree of resistance to roentgen rays than ordinary carcinoma or epithelioma. Some such neoplasms exhibit a certain measure of response to irradiation, but their regression is seldom pronounced or lasting. Exception perhaps should be made of adenocarcinoma of the thyroid gland and of the uterine fundus. Patients harboring such growths, therefore, may be given the benefit of the doubt to the extent of at least one thorough course of roentgen or radium treatment, but if this is not followed by substantial reduction in the size of the tumor and a corresponding improvement in general condition, repetition of the treatment is not likely to affect the issue. Moreover, to raise undue hope in the patient or relatives is to court loss of reputation.

Sarcoma—Sarcoma of the soft tissues is comparatively resistant to roentgen rays or radium and few such tumors are ever cured by these or any other methods of treatment. The effect of irradiation on the tumors depends largely on their situation and on the facility with which a large total dose of rays can be delivered to every part of the growth. When it projects from the surface of the trunk or involves an extremity, the method of multiple converging beams may cause marked or complete retrogression of the primary tumor, but the well known tendency of such neoplasms to rapid metastasis only too often neutralizes what might otherwise be an excellent result. The round-cell or spindle-cell varieties of sarcoma are relatively more susceptible to irradiation than the fibrosarcoma, and especially the myxosarcoma. Notoriously slow to metastasize, a primary fibrosarcoma can sometimes be made to undergo more or less pronounced regression, but it seldom disappears completely. The myxosarcoma, on the contrary, is almost completely insensitive to the rays. Bone tumors will be dealt with separately.

Bone Tumors—The most radiosensitive of all malignant bone tumors is the endothelial myeloma of Ewing, in which thorough and well planned roentgen or radium treatment may cause the tumor or tumors to disappear completely. The method of applying the treatment must vary according to the circumstances in each case, but it is important, after the growths seem to have disappeared, to give at least one more course of treatment in order to make the effect last longer. Careful clinical and roentgenologic scrutiny for metastasis should be made, because, if adequately treated, it also may disappear.

Chondrosarcoma is distinctly less radiosensitive than endothelial myeloma, but somewhat more so than the true osteogenic sarcoma of bone. Few chondrosarcomas or osteogenic sarcomas are ever permanently cured by any method of treatment, including surgical amputation of the affected extremity. Almost invariably metastasis to the lungs robs the radiologist as well as the surgeon of the opportunity to boast of a successful result. Nevertheless, regression of the tumor and temporary improvement in the condition of the patient may often be brought about. The earlier and the more thorough the treatment, the greater the chance of at least temporary, and possibly of permanent, success.

The tendency of bone tumors to develop in children brings up one point that must not be lost sight of. Irradiation of the rapidly growing bones or muscles of a child is prone to retard or permanently interfere with the growth of these structures. This is a minor evil in comparison with the lethal tendency of the neoplasm, but the attending physician, surgeon or radiologist should be aware of this fact and should impart his knowledge to the family beforehand in order to avoid ultimate disappointment and recrimination. The older the child the less the tendency of the rays to produce such an effect, but if children are less than 10 years of age, more particularly if they are less than 5, exposure to radiation of sufficient intensity has a marked regressive action on the tumor, but if repeated several times at intervals of from three to six or eight weeks, a deleterious effect will be produced on the subsequent growth of bones and muscles exposed to the direct action of the rays. Another point to which it may be well to call attention is that excessive irradiation, after causing regression of the tumor, may lead to abnormal repair of the bone, and this may mislead the physician into believing that the malignant process is still active when it is not.

Myeloma—In many cases myeloma is not discovered until the process is rather general and has affected many bones. This is probably because, for some time after the onset of the disease, the symptoms are not sufficiently severe to cause the patient to seek medical advice early. When the malignant process is not too widespread, roentgen irradiation may result in considerable and sometimes marked improvement, which may continue for months or even for more than one year. Substantial improvement may likewise be obtained when the disease has involved many parts of the skeleton, but in this event the degree of improvement usually is smaller and the improved condition of the patient does not last so long.

Metastasis from Bone Tumors—The majority of neoplasms primarily affecting bone metastasize to the lungs. Pulmonary metastasis from endothelioma can often be influenced to some extent by adequate irradiation, but such influence is seldom marked or prolonged. Extension of the malignant process to other

bones also may be arrested or controlled for a time but, under these circumstances, a cure is out of the question. Nevertheless, pain and disability may be sufficiently relieved to make treatment worth while. Not infrequently the metastatic tumors prove as radiosensitive as the primary growth and may disappear completely, later, metastasis to other bones and gradual physical disintegration occur.

Metastasis to the lungs from chondrosarcoma or osteogenic sarcoma seldom can be appreciably influenced by irradiation, and all therapeutic efforts usually prove unavailing.

Metastasis to Bones from Primary Tumors in Uterus, Rectum and Bladder—In the majority of cases metastatic bone lesions secondary to cancer of the uterus, rectum, bladder and other organs seldom can be controlled for more than a short time by irradiation, but pain may often be relieved and perceptible, temporary improvement in the general condition of the patient may sometimes follow thorough irradiation.

Brain Tumors—Since nerve cells naturally possess a high degree of resistance to roentgen rays, tumors of the brain also are comparatively insensitive to irradiation. Yet, probably because such neoplasms are largely made up of embryonal cells, radiotherapy may often cause the neoplasms to retrogress for months and sometimes for several years, with corresponding improvement in the condition of the patient. This is because the anatomic situation of the cerebrum and cerebellum and the conformation of the head make it possible to administer to the tumor very large doses of rays. In such cases an exceptional opportunity is offered to utilize the method of multiple converging beams. From four to eight beams of rays may be concentrated from as many different angles, often with excellent, though temporary, results. Unless a large quantity of radium is available and permits the treatment of such tumors from a distance, much as in the case of roentgen rays, the latter are to be preferred, because a larger dose of radiation can thus be delivered to the growth itself. The more cellular the neoplasm, the greater the influence of the rays, irradiation has much less effect after the tumor has become cystic. Roentgen rays of short wavelength are the most efficacious and at least three courses of treatment, each requiring from four to eight days, according to the number of fields irradiated, at intervals of six weeks, should be given. This may be usefully repeated later in the event of renewed malignant activity and recurrence of symptoms.

If a quantity of radium sufficient for thorough cross-fire of the entire tumor from a distance is available, radium treatment may be as effective as treatment with roentgen rays, and possibly more effective. But to attempt to treat an intracranial tumor with 50 mg of radium or less is not likely to yield great improvement.

Tumors of the Hypophysis—Much the same may be said of tumors of the hypophysis. In a certain proportion of such tumors repeated exposure of the hypophyseal region through multiple fields is followed by relief from headache and improvement in vision. Unfortunately, the relief thus obtained is not permanent as a rule, although it may last several months or even several years.

General Considerations—"Deep Therapy" For many years radiotherapists and physicians in general have come to speak of superficial or deep roentgen therapy. The expression "deep therapy" really came

into vogue to distinguish rays of short wavelength, generated at a potential approximating 200 peak kilovolts, from the rays of long or medium wavelength used previously, and still used extensively by many radiologists. Moreover, during the past few years the therapeutic possibilities of rays generated at voltages varying between 300,000 and 1,000,000 have been investigated, and the qualification "deep" becomes all the more confusing. At the present time, such a designation only tends to mislead, because it is so often misused by physicians without any reference to qualitative distinctions. In fact, physicians who speak or write about so-called deep therapy often cannot explain what they mean by the terms "superficial therapy" and "deep therapy," which might well be discarded.

RADIATION SICKNESS

Exposure to roentgen rays is often followed by anorexia, nausea and vomiting. Some patients may present only one of these digestive disturbances, while others may have all three in a mild, moderate or severe form. A small proportion of patients may have none of these disturbances but complain only of weakness or nervousness. The intensity of such systemic reaction depends on the extent (area) of body surface and on the part of the body exposed as well as on the ease with which the digestive equilibrium of the patient may be disturbed. Exposure of the extremities to a moderate dose of rays seldom gives rise to much reaction, but large doses, especially if administered to several fields at one time, are prone to be followed by some degree of reaction. Irradiation of the head, neck and thorax often causes a systemic reaction, the severity of which varies with the dose, duration of exposure and area of surface exposed. The part of the body most susceptible, from the standpoint of radiation sickness, is the upper half of the abdomen. This circumstance, together with the fact, demonstrated by experiments on animals that the small intestine is the most radiosensitive portion of the digestive tract, has caused the idea to be advanced that radiation sickness is due to the influence of the rays on the small intestine. Such a view is unsound because, while exposure of the small intestine undoubtedly tends to increase the systemic reaction, the reaction so commonly follows exposure of parts of the body remote from the intestine that the main cause must be sought elsewhere. Of the many hypotheses that have been offered to explain the phenomenon, the one that has the greatest number of adherents is that radiation sickness results from the circulation throughout the system of toxic products of cellular destruction in organs and tissues particularly sensitive to the action of the rays.

Numerous efforts have been made to prevent or counteract such reaction, but with no great success. The importance of thorough ventilation of the treatment rooms to remove the noxious gases generated by the electrical apparatus is great. The value of numerous drugs has been thoroughly tested, none can be depended on to prevent or diminish the intensity of the reaction. Careful preparation of the patient by evacuation of the bowel and preliminary alkalinization are valuable measures. Another measure that may help to minimize the disturbance is to have the patient fast for two or three hours before and after a treatment session. One should avoid giving too great a dose at one session or crowding a course of treatment into too short a period. In some instances unsweetened lemon juice in iced water, sipped spoonful by spoonful, may tend to allay gastric irritability, in others champagne,

if available, or ginger ale may have the same effect. In many instances, however, the reaction does not subside until several hours or days after the completion of the treatment. Even then, the anorexia may disappear slowly.

COUTARD METHOD

It is a well established principle of radiotherapy that complete regression of a tumor requires a certain dose of radium or roentgen rays. Such a dose varies with the natural radiosensitivity of the cells of which the growth is composed. Complete regression of squamous cell epitheliomas or carcinomas is known to require a total dose corresponding to about eight times the tolerance limit of the skin. If the tumor is at the surface and if the area that it occupies is small, an adequate dose is readily feasible. But if the area occupied by the growth is large, an adequate dose cannot be given through a single field without danger. When a large tumor projects above the surface, or when it is situated in a region that forms a natural projection, it is sometimes possible to concentrate on it a sufficient dose by directing toward it several beams of rays through a corresponding number of separate fields. Also, when the tumor is situated deeply within the body, it may be possible to arrange several beams so that they converge on the neoplasm. Even then, however, it is often difficult or impossible to give a total dose sufficient to cause the growth to retrogress completely, because the integrity of overlying or surrounding structures may not be unduly jeopardized.

Experiments on animals have shown that a dose of roentgen rays or radium sufficient for permanent sterilization of the testis of a rabbit, if given at one time, induces necrosis of the overlying skin. If such a dose is divided into five or more fractions and is given over a period of from five to seventeen days, sterilization of the testis is induced without severe or permanent injury to the skin. On the basis of many older experiments it was well known that the radiosensitivity of cells depends largely on their rate of metabolism in other words, on the rate of mitotic division or natural life cycle of the cells. Such considerations led to the postulate that irradiation at low intensity and in small daily increments over a period of time should be more effective and less prone to injure the intervening normal tissues.

On these grounds Coutard began, about 1920, to apply these principles to the treatment of epitheliomas of the pharynx and larynx. Rays generated at 185,000 or 190,000 volts were passed through heavy filters of zinc or copper, partly to diminish their intensity and partly to increase the homogeneity of the beam so as to diminish the tendency to reaction of the skin. With such a scheme of treatment, small doses were given daily or twice daily for from fifteen to fifty days or longer, and Coutard thus found it possible to deliver to the region occupied by the tumor total doses from five to eight times greater than had been possible by other methods, without permanent injury to the skin or mucous membranes. Moreover, the proportion of patients cured by this method is greater than had previously been possible by any other technic of irradiation. Other radiologists, notably at Radiumhemmet, Stockholm, have applied the same principle with radium, with equivalent, if not even better, results.

The Coutard method and various modifications are now being tested for many other kinds of tumor in different parts of the body. In fact, the danger is that such tests may be carried too far.

IRRADIATION AT HIGH VOLTAGES

Soon after the war, radiotherapy entered a new phase. Previous experience had shown that, in attempting to treat the more resistant neoplasms, especially when they were situated deep in the chest or abdomen, the rays available at that time were not as effective as they might be, this was thought to be due to the fact that the rays could not penetrate in sufficient quantity the portion of the body in which the tumor was situated. Therefore, a demand for more penetrating rays arose, and tube designers and manufacturers of apparatus proceeded to satisfy this demand by providing generators operating at from 200,000 to 300,000 volts. Such generators, with the new tubes that soon appeared, enabled the therapeutic radiologist to deliver to deeper parts of the body a much larger quantity of rays. Moreover, modifications in technic to take advantage of this development were rapidly devised. The result was that certain tumors which previously had not been amenable to radiotherapy now became so, at least to a certain extent.

In spite of these improvements, it became apparent that certain tumors were not greatly influenced by any technical variation and this led to a demand for still more penetrating rays, the idea being that, if rays of sufficient penetration could be obtained, even resistant tumors could be made to regress more than had been possible previously.

Besides the reasons that I have mentioned, still other reasons came into play. The high cost of radium prevented many institutions and private radiologists from using radium for external irradiation at a distance. Only a few institutions in the world have a sufficient quantity of radium to apply it in this way. During the last five years, generators capable of operating at from 500,000 to 1,000,000 volts have been designed, and tubes capable of producing rays at such voltages also have become available. Rays generated at such high voltages are more penetrating than those used heretofore and, while they do not correspond absolutely to the gamma rays of radium, their quality is such as to yield results that somewhat approximate those obtained with radium. Another advantage of roentgen treatment at high voltage over a large quantity of radium used for external irradiation at a distance is that at smaller expense a larger number of patients can be treated in the same space of time. While these developments in apparatus are desirable and advantageous, it must not be thought that they will replace all other apparatus now in use for roentgen therapy. Apparatus of this kind will probably enable the therapeutic radiologist to deal more effectively with some of the more resistant varieties of tumor and to this extent will probably yield better results. Also, it will probably tend to replace large quantities of radium for external irradiation but it would be an error for any one to think that installations operating at between 500,000 and 1,000,000 volts are going to revolutionize radiotherapy. No doubt, some institutions desiring to keep abreast of the times will go to considerable expense to install such apparatus, in spite of the fact that the character of the work of these institutions does not require such powerful apparatus. For the present, at least, it is important to recognize that radiotherapy at higher voltages is in the experimental stage, but even when it passes out of this stage it would seem sufficient if a few installations, properly distributed over the country, should be available.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

1 CHERRY BLOSSOM BRAND CRYSTAL WHITE SYRUP

2 CHERRY BLOSSOM BRAND GOLDEN SYRUP

Distributors—Alpena Wholesale Grocer Company, Alpena, Mich., Grand Traverse Grocery Company, Traverse City, Mich., Sault Wholesale Grocers, Sault Ste. Marie, Mich.

Packer—Pemick & Ford, Ltd., Incorporated, Cedar Rapids, Iowa.

Description—(1) A table syrup, corn syrup sweetened with sucrose. Same as Pemick's Crystal White Syrup (THE JOURNAL, April 9, 1932, p. 1268). (2) A table syrup, corn syrup flavored with refiners' syrup. Same as Pemick's Brand Golden Syrup (THE JOURNAL, April 2, 1932, p. 1159).

1 COMMANDER BRAND GRAPEFRUIT

2 COMMANDER BRAND FLORIDA GRAPEFRUIT JUICE

(WITH ADDED SUGAR SYRUP)

3 COMMANDER BRAND FLORIDA ORANGE JUICE

(WITH ADDED SUGAR SYRUP)

Manufacturer—Dr. P. Phillips Company, Doctor Phillips, Fla.

Description—1 Canned sliced Florida grapefruit sweetened with added sucrose and retaining in large measure the vitamin C content. The same as Dr. P. Phillips Florida Fancy-Cut Grapefruit Slices (THE JOURNAL, Nov. 19, 1932, p. 1781). 2 Canned Florida grapefruit juice sweetened with added sucrose syrup and retaining in large measure the vitamin C content. The same as Dr. P. Phillips Florida Grapefruit Juice (THE JOURNAL, Jan. 7, 1933, p. 43). 3 Canned Florida orange juice sweetened with added sucrose syrup and retaining in large measure the vitamin C content. The same as Dr. P. Phillips Florida Orange Juice (THE JOURNAL, Dec. 3, 1932, p. 1948).

LEXIN

VEGETABLE LECITHIN AND ASSOCIATED PHOSPHATIDES WITH COCOA BUTTER

Distributor—American Lecithin Corporation, Atlanta, Ga., and New York.

Manufacturer—Hansa Muehle, Hamburg, Germany.

Description—Soy bean lecithin and associated phosphatides with about 25 per cent cacao fat.

Manufacture—Soy bean lecithin and associated phosphatides with soy bean oil obtained as described for Margo (THE JOURNAL, Oct. 5, 1935, p. 1119), is washed with acetone to remove the oil. The lecithin residue is admixed with cacao fat (3 to 1) and any remaining acetone is distilled off. The product is packed in barrels or cans, or molded in blocks.

Analysis (submitted by manufacturer) —

| | per cent |
|-------------------------|----------|
| Moisture | 0.6 |
| Ash | 5.4 |
| Petroleum ether extract | 65.7 |
| Acetone extract | 33.8 |
| Total nitrogen (N) | 1.0 |
| Total phosphorus (P) | 2.5 |

Calories—85 per gram, 241 per ounce.

Claims of Manufacturer—An emulsifying agent for use in foods. Contains readily assimilable phosphorus in organic form.

COLLATERAL CIRCULATION IN CORONARY OCCLUSION

The ability of the body to supply the heart with an adequate collateral circulation is less than that for any other major muscular tissue. While the heart is in direct contact with other structures, it has for obvious reasons a minimum amount of continuity with those adjacent. In a recent experimental study by Beck and Tichy,¹ the possibilities of producing a collateral circulation to the heart were reported. In these experiments an extracardiac vascular bed was prepared by utilizing the pericardium, pericardial fat or mediastinal tissues. Continuity was established by the creation of adhesions. These were produced by incision of myocardium and suture of pericardium into the wound or by removal of epicardium and endothelial lining of the pericardium. The stimulus necessary to bring about vascular continuity was a reduced or subnormal pressure in the coronary bed, which was obtained either by slow or by complete occlusion of the coronary arteries. The report was based on a study of 103 dogs in which one or more operations were carried out to produce a collateral circulation to the heart, and on sixteen dogs in which various methods were used for injection of the heart through the extracardiac anastomoses. The experiments were begun with the hope of being able to destroy or obstruct the entire arterial coronary circulation and have a new collateral circulation develop to take its place. This was not successful, though in one experiment about 85 per cent of the total cross-sectional area of both coronary arteries was occluded with survival and normal activity tolerance of the animal. In many others, large branches were occluded with survival of the animal. The experiments showed, moreover, that vascularization of the myocardium from a collateral bed was slight or absent if the coronary circulation was normal. In other words, the blood vessels grow into the myocardium only when the latter has need for more blood. Beck and Tichy believe, therefore, that these

experiments demonstrate that a collateral bed can become the major source of blood supply to the heart.

In an attempt to determine whether these experimental observations could be in any way applied to man, a study was made of ninety-four human hearts in which a major coronary artery had been occluded.² All were judged to have sustained a major trunk occlusion, either because the site was identified or because the infarct was so large, so uniform in character and so situated anatomically that, despite inability to determine the exact location of remote occlusion, it could be regarded with certainty to have occurred. Only fourteen of these died following the first occlusion. If they are truly representative, it would appear that the majority (86 per cent) survive the first coronary occlusion. Moreover, most of these (70 per cent of the entire group) had periods of cardiac competence varying greatly in duration after the primary occlusion. The significance in relation to the practicability of artificially inducing a collateral coronary circulation is obvious. Anatomically two types of collateral channels develop in the dog as a result of surgically induced pericardial adhesions and the same type of anastomoses might reasonably be expected to develop in man. The superficial anastomoses between the coronary arteries in the epicardium are increased, and the epicardial barrier between the coronary arteries and the arteries of the parietal pericardium and mediastinum is destroyed so that anastomoses between them occur. On anatomic grounds it would thus appear likely that such anastomoses would serve to protect the heart against the failure of collateral coronary circulation that usually determines death.

Moritz and Beck thus summarize the situation

On the assumption that thrombotic occlusion of a major coronary artery can be recognized clinically, it is probable that the diagnosis could have been made in life in eighty of these ninety-four patients. Only fourteen patients died as the direct result of the first major coronary occlusion. Of the eighty patients who survived the first occlusion, the question is whether or not they could have been protected against disastrous results from subsequent occlusions by the production of extra-cardiac coronary collateral circulation.

In thirty-seven of these eighty cases, concomitant disease or continued cardiac incompetence rendered the operative risk unjustifiable. The remaining forty-three patients might have been benefited by the production of the additional collateral circulation. With the exception of seven patients, who died of other causes, all died of subsequent attacks of coronary thrombosis.

Thus there was a period after the first coronary occlusion in the lives of forty-three individuals when the production of extracardiac coronary collateral circulation might have been feasible and beneficial.

While surgery of the human heart is in a relatively early stage, the studies here reported seem to offer a physiologic and anatomopathologic basis for discriminative operation in certain cases of coronary thrombosis. The actual application of these principles, however, remains for future action and analysis.

GOLD THERAPY IN ARTHRITIS

The use of gold as a remedy is not new. The value of the metal has always conferred upon it possibilities for symbolic and suggestive therapy. Recently, however, gold has been used seriously and extensively. The multitude of disorders treated by such preparations is evidenced by the numerous titles listed in the *Quarterly Cumulative Index Medicus* under "Gold Therapy." Major attention has been directed toward its use in tuberculosis of various forms, asthma, arthritis and certain skin diseases.

The precise way in which gold acts is not known. It seems improbable that, in vivo, gold has any direct action on organisms. It has been suggested that it may act by "stimulating some defense forces in the patient,"¹ most probably the cells of the reticulo-endothelial system. Such an action is similar to that of nonspecific proteins. Gold is excreted largely through the kidneys and to a lesser degree through the intestine and bronchial mucous membrane. In the experimental nephritis of rabbits given large amounts of gold, excretion takes place mainly through the convoluted tubules, the glomeruli taking little if any part. The glomeruli remain undamaged except for slight intraglomerular congestion observed in a few cases. The nephritis produced therefore seems to resemble that caused by mercury bichloride. The elimination, however, does not occur quantitatively or rapidly, and an unknown proportion of the gold is probably retained in various tissues for a considerable time.

Although scientific reports on gold therapy are infrequent in the domestic literature, several recent reports have appeared in continental and British journals, especially with reference to its use in rheumatoid arthritis. In one by Slot, Deville and others,² six cases of acute and subacute rheumatism and fourteen of rheumatoid arthritis were treated with different preparations of gold. The clinicians concluded that in acute and subacute rheumatism in children aurotherapy is of no great value and that it is contraindicated when severe carditis is present. In rheumatoid arthritis, on the other hand, the results of gold therapy seemed superior to other methods.

Forestier,³ who reported a great deal of work on the subject, discusses the actions and reactions of gold, the choice of salt and the results of treatment in some types of joint disease. He feels that gold salts in oil suspension given by the intramuscular route are the most satisfactory and that typical rheumatoid arthritis and perhaps early ankylosing spondylitis are the most promising clinical types. Several series of treatments were given successively at intervals of from six to eight weeks. The first sign of improvement, he says, was relief from pain, and the patient was able to perform

movements impossible before treatment. The second sign was reduction of swelling and its eventual disappearance. There was also improvement in the general health, appetite and weight. The laboratory tests (sedimentation rate and resorcin flocculation test) become normal gradually. He reports that he has treated more than 500 patients with various preparations and from 70 to 80 per cent have responded well. Of these, 50 per cent of recent cases and from 20 to 30 per cent of cases of more than two years' duration are reported to have been permanently cured by from two to five series and have remained cured without further treatment for from two to three years. Of course, similar results have been reported for other methods of treatment, including nonspecific proteins, vaccines and even physical therapy.

Recently Pemberton⁴ has reported the results of gold treatment of 100 cases of chronic arthritis. Three types of preparations were used, the most recent being sodium gold thiomalate. Up to 2 Gm was given intramuscularly in oily suspension in graduated doses over a period of six weeks or more. The results were somewhat clouded by the use of some other measures but were nevertheless more than suggestive. Twelve of the cases showed apparent cure, thirty-eight were much improved, thirty-eight were improved and twelve remained the same.

Hartfall and Garland⁵ reported another series of 100 cases observed and treated over a period of two years. They favored the intravenous method of administration, using gold sodium thiosulfate. Ten showed apparent cure, fifty-six showed marked improvement, five showed none and three patients died.

All reports are in agreement on the toxicity of gold compounds. Erythematous and even exfoliative dermatitis may be observed. Nephritis with albuminuria, edema and sometimes raised blood urea may occur. A tendency to bronchial irritation has been noted. Shock and collapse occurring immediately after an injection have been reported. Pyrexia has been reported more often by some observers than by others and is probably more frequent when an intravenous preparation is used. Stomatitis and diarrhea sometimes occur. Hartfall and Garland recorded toxic reactions in forty-five of their hundred cases. The most common was generalized pruritus, which occurred in thirty-six cases, erythema developed in twenty-eight of these and four went on to desquamation, in one case severe. Diarrhea developed in ten cases. Soreness of the mouth was complained of in nine cases and three went on to ulceration. In four cases vomiting occurred within a few hours of the injection and one patient had immediate nausea without vomiting. Isolated cases of hyperkeratosis of the soles, pustular dermatitis of the hands and feet, labial edema, herpes zoster, erythema nodosum, lichen

3 Forestier Jacques. *Rheumatoid Arthritis and Its Treatment by Gold Salts*. *Lancet* 2: 646 (Sept. 22) 1934.

4 Pemberton H S. *One Hundred Cases of Chronic Arthritis Treated by Gold*. *Lancet* 1:1037 (May 4) 1935.
5 Hartfall S J and Garland H G. *Gold Treatment of Rheumatoid Arthritis*. *Lancet* 2: 8 (July 6) 1935.

planus and purpura were noted. Three of their patients died. One of these developed agranulocytosis three months after the last injection. Two died of purpura, most likely due to the injections. Hudson⁶ has reviewed the cases of gold purpura. In eleven of the twenty-two cases under consideration a previous course of aurotherapy had been given, thus suggesting sensitization. The only efficient safeguard, he believes, is systematic platelet counts. In case purpura occurs, blood transfusion should be given without delay.

Thus there is now a considerable amount of independent work indicating the therapeutic effectiveness of gold salts in rheumatoid arthritis. The best preparation, mode of administration and dosage are not a matter of general agreement. The toxicity is marked. The conservative attitude that must still be taken is indicated by the fact that the Council on Pharmacy and Chemistry has not yet accepted any therapeutic gold preparation with claims of usefulness in arthritis. It seems that aurotherapy is promising in a restricted field when some of the doubtful factors become clear and the necessary precautions against toxic reactions standardized. At the present time no one who is not thoroughly familiar with the indications and dangers should attempt its use.

Current Comment

THE NATIONAL FORMULARY VI

When Congress created the Food and Drugs Act in 1906 it included as official standards for the purpose of the act not only the United States Pharmacopeia but also the National Formulary, a book published by the American Pharmaceutical Association. The first Formulary appeared in 1888. At that time the committee stated that "there is and shall be only *one* standard, as to quality and strength, to be followed for all official preparations, viz., the United States Pharmacopeia." The National Formulary—which is, at most, intended only as a stepping stone from and to that authority—was characterized as a standard only for those preparations which are not provided for by this official work. The book may be considered, then, as an interim depository for those drugs which do not merit therapeutic recognition by the U. S. Pharmacopeia. In some ways it seems unfortunate that the life of these drugs should be continued by finding recognition in the official compendium. There are those, however, who feel that since some of these drugs are prescribed by some physicians they should be standardized. The National Formulary is also continuing the policy of being what its name implies—a formulary of certain mixtures, many of which are simply dosage forms of the Pharmacopeial drug. The National Formulary Committee is appointed by the American Pharmaceutical Association. The present committee consists of fifteen pharmacists and one physician, the membership being confined to members of the association. The

chairman of the committee, who has worked indefatigably on this venture, is Prof. E. N. Gathercoal of the University of Illinois. The Sixth Revision,¹ which is now available, is superior to previous issues in that it follows the style of the Pharmacopeia rather than being divided into three sections. Eighty of the 119 articles omitted from the Pharmacopeia have been incorporated in this volume. There are 150 other admissions and 319 deletions. The largest single group addition is the Ampules, some containing certain new and old Pharmacopeial items. The National Formulary lists certain types of tablets but, unlike its predecessor, does not prescribe as rigorous standards for the preparations. Essentially, any size tablet of the preparation described in the National Formulary now becomes official. It is interesting to note also that glandular preparations have been included in the National Formulary, but it must be admitted that there is no evidence of the value of some of these preparations given orally. Among them are ovary, corpus luteum and anterior pituitary. The sincerity of the committee that has charge of this work is recognized, but the National Formulary still seems to be a superfluous publication. There should be only one book of official standards for medicinal preparations published in the United States.

THE TREND OF SYPHILIS AND GONORRHEA IN THE UNITED STATES

The report by Usilton,¹ on the trend of syphilis and gonorrhea in the United States provides evidence of the enormity of the venereal disease problem. Annually there are apparently four per thousand individuals in the United States with a fresh syphilitic infection and eight per thousand with acute gonorrhea. An additional four per thousand seek treatment for the first time after their syphilitic infection has become late, and another four per thousand present themselves to a physician for treatment of chronic gonorrhea. Thus, more than a million persons seek medical treatment for syphilis in the United States each year, while more than 1,500,000 persons are treated annually by physicians for gonococcal infection. Eighty-four per cent of patients treated for early syphilis in five of the large clinics devoted to syphilis failed to remain under treatment until the disease was rendered noninfectious. In fact, surveys conducted by the American Social Hygiene Association reveal that twice as many persons with venereal disease seek treatment across drug-store counters as come to a qualified medical source for treatment. If two thirds of patients with fresh syphilis who seek authorized medical treatment lapse from treatment before they become noninfectious to others, if more than 500,000 persons each year do not seek treatment until one or more years after acquiring syphilis, and if two thirds of those who acquire the disease seek "drug-store treatment" or receive no treatment, nearly two million persons in the United States are either inadequately treated or fail to receive treatment for syphilis every year. Usilton also makes the significant statement that approximately 186,000 of the potential

⁶ Hudson, E. H. Purpura Haemorrhagica Caused by Gold and Arsenical Compounds. *Lancet* 2: 74 (July 13) 1935.

¹ A comprehensive review of this book will be published in a later issue.
¹ Usilton, L. J. Trend of Syphilis and Gonorrhea in the United States. Based on Treated Cases. *Ven. Dis. Inform.* 10: 147 (May) 1935.

mothers of this country have active syphilis, with the likelihood of resultant loss of the child four times more often than among nonsyphilitic mothers. These figures provide emphasis to Usilton's statement that 'syphilis as a treatment problem ranks first among the contagious diseases of man'.

Association News

ABSTRACTS OF MINUTES OF BUSINESS MEETING HELD BY COUNCIL ON MEDICAL EDUCATION AND HOSPITALS IN CHICAGO, DECEMBER 8 AND 9

1 The meeting was called to order at 10 a. m. Those present included Drs Ray Lyman Wilbur (chairman) Merritte W Ireland Frederic A Washburn, J H Musser, Fred Moore Reginald Fitz, William D Cutter, Herman G Weiskotten, Carl M Peterson, Oswald N Andersen and Mr Homer F Sanger.

2 It was resolved that the minutes of the business meeting of Sept. 15, 1935, be approved.

3 It was voted to reconsider the resolution passed in September to the effect that after July 1, 1938, the Council would no longer list two year schools and it was further voted that such schools be considered individually.

4 It was voted that the nineteen sophomore students at present enrolled in the University of Mississippi School of Medicine may be accepted in approved schools without prejudice to the standing of the latter.

5 It was voted that the American Board of Dermatology and Syphilology be approved.

6 It was voted that the American Board of Radiology be approved.

7 It was voted that the list of pathologists as submitted be approved.

8. It was voted to approve the lists of hospitals and other institutions recommended by the staff.

WILLIAM D CUTTER M D, Secretary

RADIO BROADCASTS

The American Medical Association broadcasts over WEAf, the Red network instead of the Blue as formerly, and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health. The program is recognizable by a musical salutation through which the voice of the announcer offers a toast 'Ladies and gentlemen, your health!' The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

Red Network—The stations on the Red network of the National Broadcasting Company are WEAf, WEEI WTIC WJAR, WTAG, WCSH, WFI-WLIT WFBR WRC WGY, WBN WCAE WTAM, WWJ WSAI, WMAQ-WCFL KSD, WOC-WHO, WOW and WDAF.

Pacific Network—The stations on the Pacific network are KGO KFI, KGW, KOMO and KHQ.

The next three programs are as follows:

December 31 No broadcast
January 7 Infantile Paralysis Morris Fishbein M D
January 14 Diphtheria W W Bauer M D

This program is broadcast occasionally on the short waves through KDKA Pittsburgh over station W8YK, 11,870 and 12,210 kilocycles.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

University News—Dr John H Musser, professor of medicine Tulane University of Louisiana School of Medicine New Orleans gave a lecture at the University of Alabama School of Medicine recently, his address was entitled "The Life and Work of Sir William Osler, with Some Personal Reminiscences." The occasion was the observance by the Gorgas Medical Society of the university of the birthday of Gen. William Crawford Gorgas.

ARKANSAS

Society News—Dr George E Knappenberger Kansas City, Mo. discussed "Gastro-Intestinal Disorders" before the Benton County Medical Society, November 14.—Speakers before the Sebastian County Medical Society, November 12, were Drs Miles E Foster and Arthur F Hoge, Fort Smith, on "Thyroid Surgery" and "Surgery in Diabetes".—Among others Dr C W Rasco DeWitt presented a "Review of Recent Literature Regarding Undulant Fever" before the Arkansas County Medical Society in Stuttgart, November 12.

CALIFORNIA

Lectures by Dr Houssay—Dr Bernardo A Houssay, professor of physiology and director of the physiologic institute in Buenos Aires, Argentina lectured at Stanford University, December 7, and at the medical school December 9, on "The Hypophysis and Resistance to Infection, Intoxication and Cancer." Lectures were also presented before the University of California School of Medicine and the California Academy of Medicine, December 14.

Society News—Dr Curle Latimer Callander San Francisco, discussed "A New Amputation" before the San Diego County Medical Society, December 10.—At a meeting of the Alameda County Medical Association, December 16 speakers were August Vollmer on "The Problem of Crime as Related to Medicine," Paul L Kirk, Ph D Berkeley "Application of Scientific Principles in the Investigation of Crime," and Dr Hubert N Rowell Berkeley, "Medicopsychological Aspects of Crime."

Auxiliary Sponsors Health Meetings—The women's auxiliary of the Alameda County Medical Association sponsored a health institute at the Oakland Civic Auditorium November 4-5 'to present to the public the fundamental facts of modern scientific medicine for the purpose of building sound public opinion and knowledge relative to the questions of public and private health. Local medical organizations and civic agencies cooperated. Exhibits were included depicting important phases of personal and community health.

Survey of the Blind—In a survey in California, 3,512 blind persons responded to questionnaires issued to 6,960 blind persons who were recorded in the census. Of the group studied, 121 per cent were under 20 years of age while 54.4 per cent were more than 60. Only eighty-eight of the 3,512 persons surveyed reported that they make even a bare living, while about 95 per cent of the blind in California have no earned income at all and so are wholly dependent economically, either on relatives and friends or on society. The study was sponsored by the bureau of rehabilitation of the state department of education and carried out in cooperation with the state emergency relief administration and the state council for the blind. Its purpose was to ascertain the number of blind persons in the state who are self supporting, the number who are of employable age and in what occupation they have been successful and the number needing aid for economic or social adjustment.

COLORADO

Personal—Dr Robert W Gordon has been appointed deputy manager of health and charity of the health department of Denver, succeeding Dr Bertram B Jaffa.

Society News—The annual midwinter graduate clinics of the Colorado State Medical Society will be held in Denver, January 23-24.—Dr Ralph A Fenton Portland, Ore, discussed "Facts and Fallacies Regarding Accessory Sinuses" before the Colorado Oto Laryngological Society, November 16.

GEORGIA

New Society of Pathologists—The Georgia Association of Pathologists was organized recently with seventeen charter members. Atlanta will be the headquarters of the new society, and officers are Drs Everett L Bishop, president, Roy R Kracke, vice president, and Thomas F Sellers, secretary. Meetings will be held monthly.

Society News—Speakers before the Georgia Pediatric Society in Atlanta, December 12, included Dr Isaac A Abt, Chicago, on "Progress of Infant Feeding" and "A Child's Heart in Avitaminosis", Charles E Bills, Ph D, Evansville, Ind, "Medicinal Fish Oils" and "Multiple Nature of Vitamin D", Dr John A Kolmer, Philadelphia, "Infection, Immunity and Vaccination in Anterior Poliomyelitis," and Dr John L Morse, Boston, "The Thymus Delusions" and "Diagnosis and Prognosis in Pediatrics".—Dr William F Reavis read a paper entitled "Cancer in the Lower Urogenital Tract" before the Ware County Medical Society, Waycross, November 6.—An official bulletin for the Georgia Medical Society made its appearance with the October issue. The society was founded in 1804 and since 1908 has been the official medical society of Chatham County. Dr Michael J Egan is president, Dr Cornelius F Holton president-elect, Dr Harry M Kandel vice president, and Dr Otto W Schwalb secretary. All are from Savannah.

INDIANA

Portrait Presented to University—A portrait of the physician immortalized by James Whitcomb Riley in his poem "The Doctor" has been presented to the Indiana University Medical Center, Indianapolis, and hung in the reading room of the medical library, according to the state medical journal. Dr William B Fletcher, subject of the painting by Theodore C Steele, served as a scout during the Civil War. Captured near Big Spring, Va, he succeeded in destroying his notes and maps by lighting his pipe with them while seated near a camp fire, but he was condemned to be shot. After he made two unsuccessful attempts to escape, his identity as a condemned prisoner was lost and by mistake he was sent to Libby prison and was later paroled. Dr Fletcher served more than forty years as a teacher in the old Indiana Medical College and the College of Physicians and Surgeons in Indianapolis. He died in 1907.

IOWA

Typhoid Outbreak—Twenty-four cases of typhoid with one death in Polk County during the week ended November 30 were attributed to a contaminated water supply, according to the state health department. The outbreak involved with one exception persons residing, working or visiting at the county farm or attending an adjacent school. The investigation revealed the water supply to be the only factor common to the farm and the school.

Society News—A symposium on rare fevers was presented before the Decatur County Medical Society, Decatur, November 12, by Drs John C Parsons, Creston, Ernest E Shaw, Indianola, and Herbert E Stroy, Osceola.—Dr Elwood P Russell, Iowa City, discussed "Fractures of the Hip, Thigh and Knee" before the Louisa County Medical Society, November 14.—At a meeting of the Scott County Medical Society in Davenport, December 3, Dr Charles Hugh Neilson, St Louis, discussed "Effect of Weather on Human Conduct and Disease".—At a meeting of the Woodbury County Medical Society in Sioux City, November 21, Dr Edgar V Allen, Rochester, Minn, spoke on "Peripheral Vascular Disease".—A symposium on inflammatory lesions of the bowel was presented before the Northwest Iowa Medical Society in Sheldon, November 5, by Drs Harry M Weber and Philip W Brown, Rochester, Minn.

KANSAS

Changes in Health Officers—Dr James B Ungles, Satanta, has been appointed health officer of Haskell County, succeeding the late Dr Loring V Miner. Dr William J Scott, Ottawa, was recently placed in charge of the Franklin County health unit.

Society News—The Wyandotte County Medical Society was addressed, November 29, by Drs La Verne B Spake, Kansas City, on "Indications for Surgery of the Mastoid Process" and Oscar W Davidson, Kansas City, "Visceroarenal Reflexes".—Speakers before the Rush-Ness Medical Association recently in La Crosse were Drs John A Dillon, Larned, on psychosis, Albert C Armitage, Kinsley, the state medical society, and Otto A L Hennerich, Hays, otitis media.—At the annual meeting of the Kansas Hospital Association recently at Emporia, Rev J E Lander, Wichita, was chosen president.

LOUISIANA

Personal—Dr Paul T Thibodaux, secretary of the Lafourche Levee Board and coroner of the Ascension Parish for many years, has been appointed health officer of Donaldsonville, he was also postmaster of Donaldsonville for three terms, resigning this position several months ago, it was stated.

Chaillé Memorial Oration—The tenth Stanford E Chaillé Memorial Oration was delivered at the memorial meeting of the Orleans Parish Medical Society December 7. Dr Joseph A Danna gave the lecture entitled "Dr Chaillé, Dean, Teacher and Friend." Other speakers at this meeting were Drs William H Slaughter on "Present Status of Fever Therapy," and Roscoe R Spencer, "An Explanation of the U S Public Health Survey."

MARYLAND

A Year in Baltimore Without a Diphtheria Death—Not one death was reported from diphtheria in Baltimore during the year and sixteen day period ended October 13, according to the health department. Four deaths occurred in children brought into Baltimore from county homes for treatment at Sydenham Hospital, but these are classified as "nonresident" deaths. The death of a little girl occurred October 13.

Changes in Faculty at University of Maryland—Dr James Dawson Reeder, clinical professor of diseases of the colon and rectum, University of Maryland School of Medicine, Baltimore, has been promoted to the rank of professor. The promotion of Dr John Mason Hundley Jr from associate in gynecology to professor of clinical gynecology is also announced. New appointments include that of Magnus Greger sen, Ph D, as professor of physiology.

Personal—Dr John A Skladowsky was promoted, October 23, to be full time medical health officer in the Baltimore health department and was assigned to the Western Health District, he has been connected with the department since 1920.—Dr Harry Garland Timbres has been appointed assistant in biostatistics at Johns Hopkins University School of Hygiene and Public Health, Baltimore.—The work of the late Dr Joseph C Bloodgood at St Agnes Hospital, Baltimore, will be continued under the direction of Drs George A Stewart and Leopold Clarence Cohn. They will also continue his clinic at 3301 North Charles Street. These physicians had long been associated with Dr Bloodgood.

MASSACHUSETTS

Changes in Medical Examiners—Dr John L O'Toole, Haverhill, was appointed in November medical examiner of the fourth Essex district. Dr John P Creed Haverhill, was named associate medical examiner of the district, and Dr Charles R Abbott, Clinton, associate medical examiner of the fourth Worcester district.

Society News—Dr Burgess L Gordon, Philadelphia, discussed "The Mechanism and Effects of Abdominal Compression in the Treatment of Pulmonary Tuberculosis" before the Harvard Medical Society, Boston, November 26.—Speakers before the Norfolk District Medical Society in Norwood, November 26, included Dr Valmore A Pelletier, on "Metastasis in Cancer of the Breast."

MICHIGAN

Personal—Dr Kenneth W Dick, Carsonville, has been appointed medical adviser in the Michigan Home and Training School at Lapeer.—Dr Harold W Jacox has resigned as assistant professor of roentgenology at the University of Michigan Medical School, Ann Arbor, to become director of the department of radiation therapy for the Western Pennsylvania Hospital at Pittsburgh.

Society News—Dr Archibald L Hoyne, Chicago, addressed the Detroit Pediatric Society, December 4, on "Treatment of Meningococcal Infections".—Dr Clark D Brooks, Detroit, discussed "Malignancy of the Gastro-Intestinal Tract, Diagnosis and Treatment" before the Jackson Medical Society in Jackson, November 19.—A symposium on management of the more common skin diseases was presented before the medical section of the Wayne County Medical Society, December 9, the program was arranged by the Detroit Dermatological Society.

State Survey of Goiter—The state medical society and the state department of health are cooperating in a survey now being conducted in the state to determine whether the depressed income of the average family has brought about an increase of goiter cases. Questionnaires are being given to school children in which they are asked whether the use of iodized salt prevails in their families and whether it ever was used. The children

are questioned about their own diet and given a superficial examination for goiter. Samples sold by all salt manufacturers in Michigan have been collected to be tested in the state agricultural laboratory to determine whether packages sold as iodized salt contain the proper amount of sodium iodide. The results of the survey will be tabulated by the state health department in Lansing, and the conclusions drawn by the state medical society will be presented to the state emergency relief commission.

MINNESOTA

Society News—Dr Irving S. Cutter, dean, Northwestern University Medical School, Chicago, discussed "The Physician and the Public" before the St. Louis County Medical Society in Duluth, December 12. Speakers before the Medical Society of Blue Earth in November included Dr. Charles N. Hensel, St. Paul, on internal medicine; Dr. Neil Hamilton Fairley, London, gave a Mayo Foundation lecture in Rochester, November 25, on "Tropical Diseases as They Affect the Practice of Medicine in the Temperate Zone." Dr. Leo G. Rieger, Minneapolis, discussed "Development of the Use of Opaque Media in Roentgen Diagnosis" before the Rice County Medical Society at Faribault recently. At a meeting of the Upper Mississippi Medical Society in Wadena, recently, Dr. Charles B. Wright, Minneapolis, read a paper entitled "Abdominal Symptoms of Heart Disease," and Dr. Theodore H. Sweetser, Minneapolis, spoke on diagnosis and treatment of hydronephrosis. Dr. Henry E. Binger, St. Paul, was recently elected president of the Minnesota Academy of Ophthalmology and Oto-Laryngology. Vice presidents are Drs. George E. McGary and Anderson C. Hilding, Duluth, and the secretary is Dr. Walter E. Camp, Minneapolis. Speakers before the Minnesota Academy of Medicine in St. Paul, December 11, were Drs. Hendrie W. Grant, St. Paul, on "Visual Field Contractions after Head Injury," and Herbert Z. Giffin, Rochester, "Hemorrhagic Purpura."

MISSISSIPPI

Physical Examinations of Health Workers—Every health worker in the state had had a physical examination by his family physician, December 15. In addition each worker had had a dental examination, including x-ray and all corrections, typhoid and smallpox vaccination, Schick test and toxoid if positive, and roentgenogram of the chest.

MISSOURI

Society News—Dr. Carliss Malone Stroud discussed vitamins before the St. Louis Medical Society, December 10, and Dr. Cyril M. MacBryde, "Functional Changes in Liver Heart and Muscles and Loss of Glucose Tolerance Resulting from Dinitrophenol." At a meeting of the society, December 3, Dr. Ellis Fischel discussed "Cancer of the Rectum" and Dr. Millard F. Arbuckle, "Cancer of the Larynx."

Cancer Program—The cancer committee of the state medical society sponsored a meeting with the Pettis County Medical Society as host at Sedalia, November 12-14. A clinic was conducted at the Bothwell Hospital in the morning and a public meeting was held in the afternoon. Dr. Ferdinand C. Helwig, Kansas City, discussed "Causes of Cancer," Dr. Ernest Kip Robinson, Kansas City, "Prevention of Cancer of the Mouth," and Dr. David S. Dann, Kansas City, "Cancer Control." In the evening, Dr. Helwig spoke on "Reaction of Tumors to Radiation," Dr. Robinson, "Treatment of Metastatic Glands in the Neck," and Dr. Dann, "Management of Cancer of the Lip."

NEBRASKA

Society News—Dr. Arthur T. Henrici, Minneapolis, was guest speaker at the meeting of the Omaha-Douglas County Medical Society, December 10, on "Fungi in Disease." Drs. Claude T. Uren and William H. Stokes, Omaha, addressed the Platte County Medical Society, Columbus, November 14, on "Acute Infection of the Middle Ear and Mastoid" and "Treatment of Some of the More Common External Diseases of the Eye," respectively.

NEW JERSEY

"Washington Plan" Adopted—The Essex County Medical Society has established a medical-dental service bureau in the pattern of the "Washington Plan" for distribution of medical service to low income groups in Washington, D. C. It was expected that the bureau which is incorporated as a nonprofit organization, would be in operation by December 15.

Society News—Dr. Alfred F. Hocker, New York, addressed the Monmouth County Medical Society, Asbury Park, recently, on "Tumors of the Head and Neck," and Dr. Frank C. Parker, Norristown, Pa., presented a motion picture of ophthalmic operations. Dr. Paul R. Correll, Easton, Pa., addressed the Warren County Medical Society, Belvidere, recently, on "Traumatic Ruptures of the Liver and Spleen and Ruptures of Gastric and Duodenal Ulcers." Dr. Murray H. Bass, New York, addressed the Hudson County Medical Society, Jersey City, November 6, on "Unusual Forms of Rheumatic Infection in Children."

Health at Camden—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended December 14 indicate that the highest mortality rate (20.5) appears for Camden and the rate for the group of cities as a whole was 12.1. The rate for Camden for the corresponding week of last year was 15.3 and for the group of cities, 11.7. The annual rate for the eighty-six cities for the fifty weeks of 1935 was 11.3 and the same rate appeared for the corresponding period of 1934. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for large areas outside the city limits or that it has a large Negro population may tend to increase the death rate.

NEW YORK

The Will Rogers Tuberculosis Hospital—The name of the National Variety Artists' Lodge, a tuberculosis hospital at Saranac Lake for members of the theatrical professions, has been renamed the Will Rogers Memorial Hospital. The directors of the National Variety Artists' Association turned over the deed to the hospital to the Will Rogers Memorial Fund at a meeting November 21.

Society News—Dr. David L. Engelsher, Bronx, addressed the Westchester Village Medical Society, November 26, on "Allergy and the General Practitioner." Dr. Abraham Kaplan, New York, addressed the Dutchess-Putnam Counties Medical Society, Poughkeepsie, November 13, on "Diagnosis of Operable Intracranial Lesions." Dr. Bret Ratner, New York, addressed the society, December 11, on "The Allergy Problem in Childhood." Dr. Murray B. Gordon, Brooklyn, addressed the Rockaway County Medical Society, November 21, on "Endocrinology in Children."

New York City

Hospital News—A new research laboratory has been completed at St. Clare's Hospital in connection with the Tumor Institute recently established at the hospital. The laboratory is entirely separate from the laboratory for pathology. The department of hydrotherapy at the Hospital for Joint Diseases has been reorganized under the direction of Drs. Jerome Weiss attending physical therapist, and Hans Behrend, formerly of the hydrotherapeutic institute of the University of Berlin.

Scholarships at Post-Graduate School—Scholarships for qualified graduates in medicine who wish to do graduate study are available at New York Post-Graduate Medical School under the Oliver-Rea endowment. Under the terms of the agreement, applicants from Allegheny County, Pa., other circumstances being equal, will be given preference. Application should be made to the director of the school, 303 East Twentieth Street.

Society News—Speakers before the Medical Society of the County of New York, December 16, were Drs. Bernard S. Oppenheimer, on "The Era of Chronic Diseases in Medicine," James C. White, Boston, "Neurosurgery in Cardiovascular Diseases," and Richard Kovacs, "Thermal Therapy in Chronic Disease." Dr. Beverly C. Smith addressed the New York Surgical Society, December 11, on "Peripheral Nerve Block in Arterial Disease of the Lower Extremity." Dr. Nathaniel G. Alcock, Iowa City, addressed the New York Society of the American Urological Association, December 13, on "Operations on Transurethral Resections of the Prostate." Drs. James S. McLester, Birmingham, Ala., and James Tate Mason, Seattle, President and President-Elect respectively of the American Medical Association, addressed the Bronx County Medical Society at a special meeting November 25, on the activities of the Association and Dr. Frederic E. Sondern, president of the Medical Society of the State of New York, spoke on the state society's work. The International Spanish Speaking Association of Physicians, Dentists and Pharmacists, at the first meeting of the fall, November 22, held a symposium on the gallbladder with the following speakers: Drs. Henry L. Bockus and William Wayne Babcock, Philadelphia, Walter G. Crump, New York, Jose Arce, Buenos Aires, Argentin-

tina, and Eugenio Cienfuegos, Santiago, Chile. Dr Jacob M Gershberg, president of the society, gave an account of a recent European trip, where he addressed various medical societies on 'Metchnikoff's Theory of Longevity and the Colon'—Drs Lay Martin, Baltimore, and Harlow Brooks addressed the National Society for the Advancement of Gastro-Enterology December 18, on "Clinical Interpretation of Jaundice" and "Abdominal Symptoms and Signs of Thoracic Disease," respectively

OKLAHOMA

Penitentiary Quarantined—The Oklahoma state penitentiary at McAlester was placed under quarantine by the state health commissioner, December 21, when a case of cerebrospinal meningitis was diagnosed in a convict. Parts of four counties were reported to be under quarantine, December 18 when three deaths were announced in addition to one previously attributed definitely to meningitis and nine others believed the result of the disease (THE JOURNAL December 21, p 2079). Canadian, Cleveland, Kiowa and Tillman are the counties affected.

PENNSYLVANIA

Personal—Dr William Moore Guilford Lebanon, celebrated his one hundred and third birthday, November 26—Dr Lorne T MacDougall, Tunkhannock, has been appointed medical director of Wyoming County, succeeding Dr Frank J Austin, Laceyville

Philadelphia

Colleagues Honor Dr Coates—Members of the staffs of the University of Pennsylvania, Graduate, Presbyterian and Abington Memorial hospitals gave a testimonial dinner, November 16, in honor of Dr George M Coates, professor of otolaryngology, University of Pennsylvania School of Medicine, and professor of otorhinology in the Graduate School of Medicine of the university. A feature of the dinner was the presentation to Dr Coates of a portrait of himself to be hung in the school of medicine. Dr Benjamin H Shuster made the presentation

Pittsburgh

Society News—Speakers at a meeting of the Allegheny County Medical Society December 17, were Drs Eben W Fiske on 'Therapy of Rest and Motion', John W Fredette, 'Treatment of Hand Infections', Wilton H Robinson, 'Injuries of the Shoulder Girdle, with Particular Reference to the Prevention of Deformity', and Rutherford T Johnstone 'Interpretation of the Electrocardiogram for the General Practitioner'

RHODE ISLAND

Society News—Speakers at a meeting of the Providence Medical Association, December 2 were Drs Kalei K Gregory, on "Some Clinical Aspects of the 1935 Epidemic of Anterior Poliomyelitis", George M Retan Syracuse, N Y, "Treatment of Poliomyelitis by Forced Perivascular Drainage" and Maurice Brodie New York, "Present Problems of Poliomyelitis Diagnosis, Treatment and Prevention"

VIRGINIA

Society News—William T Sanger LL D, president, Medical College of Virginia, Richmond, was guest speaker before the Southwestern Virginia Medical Society in Roanoke, recently, on "Trends in Medical Education"—Drs Frank S Johns and Emmette T Gatewood, Richmond, addressed the Mid-Tidewater Medical Society at a meeting at Millers Tavern in October on "Cancer of the Colon" and "Foreign Bodies in the Trachea," respectively—Dr Martillus H Todd, Norfolk, addressed the Northampton County Medical Society, Eastville, recently, on emergency surgery—The Culpeper County Medical Society was organized recently at a meeting in Culpeper, with Dr David W Kelly Jr, Culpeper, as president, John E Parks Jr, Brandy, vice president, and Otway K. Burnette, Culpeper, secretary—Dr Charles R Austrian, Baltimore, addressed the Virginia Peninsula Academy of Medicine, November 18, on "Differential Diagnosis of Pulmonary Tuberculosis"—The quarterly session of the Southside Virginia Medical Association was held in Petersburg, December 10, with the following speakers: Drs Wyndham B Blanton, Richmond, "Medical Economics", William M Bickers, Richmond, "Ectopic Pregnancy", Herbert C Jones Petersburg, "Intravenous Pyelography", Leta J White and George H Reese, Petersburg, "Congenital Pyloric Stenosis", Henry M Snead, William B McIlwaine III Petersburg, and Thomas F Wheelton, Richmond, "Unusual Cases of Paralysis"—Dr W Ambrose McGee, Richmond opened the discussion

GENERAL

News of Epidemics—Three cases of epidemic meningitis were reported in Lawrence County, Ark., December 5. Two cases were discovered in Washington, D C in November—An outbreak of twenty-three cases of diphtheria was reported from Fort Wayne, Ind., December 4—A Civilian Conservation Corps camp at Red House, N Y, was quarantined for several days early in December when a case of scarlet fever was discovered. Schools were closed in Waukesha, Wis., to combat an outbreak of scarlet fever during November—An epidemic of 497 cases of mumps was reported in Fargo, N D, in November—Thirty-four cases of typhoid in the vicinity of Saylorville, Iowa, were attributed to contaminated water on the Polk County farm, December 4

Changes in Status of Licensure—The New Mexico Board of Medical Examiners recently reported the following actions:

Dr John L Kirby, Clovis license revoked because of his conviction on a narcotic charge

Dr James Monroe Wattam Carlsbad license revoked because of alcoholism

Dr George Frear Johnston formerly of Clayton license revoked on the ground that he is an impostor using the license of a physician of the same name who died several years ago

The Massachusetts Department of Registration recently reported the following action:

Dr John F Cummings Brockton license revoked November 15 for conviction in court on a charge of abortion

The Arizona State Board of Medical Examiners reports the following:

Dr Claude E. Duvall Tucson license revoked December 3 for violation of the Harrison Narcotic Act

Medical Section of Science Association.—At the mid winter meeting of the American Association for the Advancement of Science in St Louis, December 30-January 3, Section N (Medical Sciences) will have a program each morning. Two sessions, those of Thursday and Friday, will be devoted to symposiums on the sex hormones. Among speakers will be Dr George W Corner, Rochester, N Y, Edward A Doisy, PhD, St Louis, G F Marrian Toronto, Dr Carleton J Marinus, Detroit, Dr Willard M Allen, Rochester, N Y, Dr Howard F Kane Washington, D C., and Charles W Turner, PhD, Columbia, Mo. Dr Stanhope Bayne-Jones New Haven, Conn, vice president for the section, will present his official address, January 1, in the afternoon on 'Bacterial Poisons and Their Antidotes'. The preceding afternoon Dr Bernardo A Houssay, Buenos Aires Argentina, will speak on "The Pituitary Gland and the Metabolism of the Body."

Orthopedic Surgeons to Meet.—The fourth annual convention of the American Academy of Orthopedic Surgeons will be held in St Louis, January 13-16, with headquarters at the Hotel Jefferson. The program includes two symposiums. Drs. Richard H Jaffe, Chicago, Robert I Harris and Arthur C Singleton, Toronto, and Henry W Mejerding, Rochester, Minn., will present a symposium on bone tumors, the other on "Fractures About the Elbow," will be presented by Drs William Darrach, Clay Ray Murray and Philip D Wilson, New York. H Earle Conwell, Fairfield, Ala., James S Speed Memphis, Tenn., and Alfred R Shands Jr, Durham, N C. Other speakers announced include:

Dr Donald E King San Francisco The Question of Healing and Regeneration of the Internal Semilunar Meniscus

Dr Edward L Compere Chicago Indications for and Against the Leg Lengthening Operation

Dr Alexander Gibson Winnipeg Manit A Method of Spinal Fusion

Dr Mather Cleveland New York Lateral Curvature of the Spine

Following Thoracoplasty in Children

Dr Arthur Bruce Gill Philadelphia An Evaluation of Present Day Methods of Dealing with Congenital Dislocation of the Hip

Dr William B Carrell Dallas Texas Use of Fascia in Unstable Knees

Dr John Albert Key St Louis Metabolic Factors in the Diagnosis and Treatment of Hypertrophic Arthritis

Dr Joseph Kite Decatur Ga Treatment of Congenital Clubfoot

Dr Frank D Dickson, Kansas City, Mo., is president of the academy, Dr Melvin S Henderson, Rochester, Minn., president-elect, and Dr Philip Lewin, Chicago, secretary

Deaths in Other Countries

Charles Richet, professor of physiology, University of Paris, winner of the Nobel Prize in Medicine in 1913 died December 3, aged 85—**Griffith Evans**, Bangor, Wales, December 3, aged 85—**Griffith Evans**, Bangor, Wales, pioneer veterinary surgeon, who discovered Trypanosoma Evansi to be the cause of surra, a disease of horses and cattle, died December 7, aged 100

The Birth Control Controversy

At present there is a controversy on the subject of birth control. On the whole the medical profession is in favor of birth control under certain circumstances, while it is opposed by certain ecclesiastics, on religious or moral grounds and is entirely condemned by the Roman church. At the Hunterian Society a debate was opened by the bishop of St Albans who entirely opposed birth control by artificial means. He had a strong intuitive sense that the whole thing was wrong and degrading, and in all esthetic and moral judgments the intuitive sense was not to be disregarded. Birth control was a deliberate frustration of the biologic ends of nature. Self control he exalted as the thing which differentiated man from the animal.

Dr C P Blacker, secretary of the Eugenics Society, said that the central question was whether it was possible for the married to regulate an appropriate number of births by the method of abstinence. He had been impressed lately by a number of books from Catholic sources advocating the so called safe period. It was clear that Catholic physicians and priests were finding difficulties with their patients and penitents in this regard.

Sir Walter Langdon Brown, emeritus professor of physics in the University of Cambridge, said that the world was overshadowed by war, the aggressor being a country trying to find room for its teeming population and yet in the criminal code of the same country birth control was ranked side by side with banditry. Birth control was directed to life and health, so that a woman would be able to space her family at the proper intervals and give each member a chance of being properly brought up. He believed that celibacy was possible to many and that marriage was the crown of human happiness but that married celibacy was the worst thing possible. He preferred birth control as an alternative to those things which in the old days were regarded as of divine ordinance—war, pestilence and famine.

In the general discussion a young physician said that if physicians did not believe in birth control because it was an interference with nature, logically they ought not to try to prevent or postpone death, for this also was an interference with nature.

Road Accidents and Lighting

To what extent motor accidents are due to poor road lighting is not easily ascertained but statistics suggesting that it is the cause of many injuries were given in an address by Mr E C Lemov, vice president of the Association of Public Lighting Engineers, at the Public Works, Roads and Transport Congress, held in London. The density of traffic on the roads, he said, was not only steadily increasing but steadily increasing during the hours of darkness. Heavy goods traffic was being carried to an ever greater extent on the roads at night, and this with the enormous development of omnibus service, has contributed to make us 'an eighteen hour nation.' Statistics showed that the accident hazard at night was several times greater than by day. He estimated that if the main roads were efficiently lighted, making the use of motor headlights unnecessary, accidents would be reduced by 10 per cent and the increased cost would be counterbalanced by the reduced cost of what the community paid for accidents through insurance companies alone. More than 46 per cent of accidents occurred during the winter months, although traffic was then less heavy than in the summer. In the winter 52 per cent of accidents occurred during the dark hours and in summer more than 20 per cent, when there

was least traffic. In a whole year one third of the accidents happened during the dark hours. During the two hours of the session of the congress on the average two persons would be killed and sixty-two injured. If the session had been between the hours of 5 and 7 in the evening, in the dark when traffic would be less, the figures would have been 43 killed and 132 injured. These figures could easily be reduced by better public lighting.

In the discussion that followed it was stated that experience at Lewisham (South London) showed that better lighting led to greater speed of motorists and that it was a question how far improved lighting tended toward safety. A county surveyor said that the present system of lighting was detrimental to good driving because lights placed up in the air, particularly on a gradient, had a dazzling effect on drivers. It might be possible to floodlight the highways in such a way that the light itself would not be visible.

Discovery of a New Blue Dye

The discovery of a new blue dye possessing all the qualities demanded of a pigment is announced by Imperial Chemical Industries Ltd. It is named Monastral Fast Blue BS and is the first discovery of a blue pigment in more than a hundred years. The two blues at present most used are ultramarine, discovered as long ago as 1704 and prussian blue, discovered in 1826. Until now blue has been the most difficult color in the spectrum, and no blue has given complete satisfaction. There are seven criteria by which a pigment is judged, and even the most efficient blues fail in at least two of these. Thus ultramarine, among other faults, is destroyed by dilute acids and prussian blue by alkalis. Monastral blue fulfils all the qualifications demanded of a pigment. These are fastness to light, heat, acids and alkalis, chemical inertia, high tinctorial value and brilliance of shade. Efficient pigments representing all the colors of the spectrum have been discovered. It is thought that the new pigment will be of particular value in the making of printing ink and particularly for three-color printing. Being chemically inert it may be used in oil painting without risk of detrimental effects. Possibly it may be useful in histology.

International Congress of Physical Medicine

The sixth International Congress of Physical Medicine will be held in London, May 12-16, 1936. This will be the first occasion on which the congress has met in Great Britain. The following will be the principal officers: president, Lord Horder, chairman of executive committee, Sir Robert Stanton Woods, chairman of general committee, Sir Henry Gauvain, honorary secretary, Dr Albert Eidenow, honorary assistant secretary, Dr Alexander Cawadias. Those who wish to attend the congress are requested to communicate with the honorary secretary, Dr Albert Eidenow, 4 Upper Wimpole Street, London, W. 1. The fee for membership is \$10.

A Device for the Protection of Radium Operators

The resumption of the use of a 4-Gm bomb of radium at the Westminster Hospital, reported in a previous letter, has raised the question of the safety of the operators who will be near this powerful source of radiation, and precautions are being taken. While the bomb will be continuously used for the whole twenty-four hours of the day, no operator will work longer than eight hours. During this time he has to spend an average of two minutes each hour in adjusting the bomb to the patient. It is the cumulative effect of these small exposures over a period of months or years that causes concern. In addition to the usual precautions of periodic blood examinations, rest and vacations, and screening of the radium, a new telltale has been devised by the physicist of the hospital. When going on duty the operator will take from a cabinet a small tube of elektron metal and at the same time operate a clocking-in apparatus which indicates the time he starts work. He places this telltale

in his pocket. When he comes off duty he replaces it in the cabinet and at the same time clocks out. The telltale contains a thin rod of insulated elektron charged to about 400 volts. The radiation which the operator encounters in the course of his work causes leakage of the discharge, and this is a measure of the dose of radiation which he receives. Thus a daily record is kept of his exposures. If this is found to be too great, immediate steps can be taken.

Red Cross Airplane for Abyssinia

In response to a request from Lady Barton, wife of the British minister to Abyssinia, an airplane for Red Cross work is about to be sent by the Woman's Advisory Council of the League of Nations. How much it is needed is shown by Lady Barton's statement that while the Ethiopian Women's Work Association (which she helped to form) is supplementing the Red Cross in every possible way, it will take the Unit for the North five weeks to get to the front from Addis Ababa. An experienced airman has offered to fly the airplane without payment from England and will take a pilot, who will remain in the employment of the Ethiopian Red Cross Society.

Nov. 15, 1935

The French Orthopedic Congress

The seventeenth annual meeting of the French Orthopedic Society was held October 4. M. Meyer of Strasbourg presented a paper on "Mycotic Infections of Bones and Joints." A good clinical classification of these infections is as follows: the Aspergilloses, the Blastomycoses, the Actinomycoses or Oosporoses, the Sporotrichoses and the Hemisporoses. The history of the clinical discovery of each of these five varieties of mycotic infections was discussed. The portal of entry is most commonly at some point in the alimentary tract, rarely by way of the respiratory organs or as the result of injury. The infection involves the bony structures by invasion either from an adjacent focus in the soft tissues or by the hematogenous route. When the bone infection appears to be primary, a search should always be made for an atrium elsewhere that has been overlooked and probably healed at the time the bone focus appears. A primary mycotic throat infection is a possible atrium. The bone lesions due to the different forms of mycotic infection do not differ in any respect from those due to the ordinary pyogenic organisms. Aside from the yellow granules seen in actinomycosis there is nothing that enables one on gross examination to distinguish one form of mycotic infection from another. Meyer believes that the most characteristic feature is the tendency for the various mycoses to give rise to a localized infection with rarefaction of bone and a well marked "shell" of osteosclerosis. Certain forms give rise to tumor-like formations. Microscopically, each type of infection gives rise to characteristic pictures as a rule, but there are often such protean changes that the diagnosis of a particular mycosis cannot be made until a typical histologic picture and the organism are found in the sections of tissue.

Clinically there are no pathognomonic symptoms. The predilection for involvement of the spine, metatarsal and metacarpal bones and phalanges makes a differentiation from tuberculosis difficult. Localization in the bones of the forearm, tibia and skull resembles syphilitic infection. A mycotic periostitis without suppuration simulates a syphilitic periostitis and, when there is pus formation, a suppurative pyogenic periostitis. In some cases there is acute bone involvement with such high fever, chills and severe pain that it is difficult to distinguish a mycotic from an acute pyogenic osteomyelitis. The same is true of the more chronic cases. There is a fulminating form the patient dying with symptoms of an acute septicemia.

When the bone is invaded from an adjacent focus, it is seen on roentgen examination to be eroded without any periosteal reaction. In the hematogenous types, roentgen examination reveals one of three changes: a sclerosing osteitis with periosteal thickening, an osteomyelitis with necrosis or an intraosseous gumma in the form of a central abscess surrounded by an osteosclerotic shell.

A differential diagnosis on examination of the films is not difficult from tuberculosis or the polycystic forms of hereditary syphilis or chronic bone abscess. Although there is nothing pathognomonic about the roentgenographic appearance of mycotic bone involvement, one should always be on the lookout for such an infection.

In general, unless the pus from the sinus leading to a bone or joint focus is examined for mycotic infection there is nothing to distinguish such a type of infection from that due to ordinary pyogenic organisms. Early infiltration and a peculiar purplish discoloration of the overlying skin and the presence of multiple fistulas should lead one to look for a mycosis. To detect the latter in the laboratory requires a good deal of experience. If no fistulas exist, an effort should be made after making a small skin incision to obtain some of the secretion with the aid of a pipet. When fistulas exist, the mycotic agents of infection often disappear because of the presence of secondary invaders. The pus should be examined in smears, by hanging drop, by inoculation on culture mediums and into animals.

Mycotic infection of the vertebrae simulates closely that due to tubercle bacilli. The diagnosis is often made only at necropsy. On roentgen examination the only distinctive features of a mycotic infection are the superficial erosion of the bodies of the vertebrae, intervertebral disks and the transverse and articular processes, the last three being seldom involved in tuberculosis. As to joint involvement, this most commonly affects the knee either primarily or as a part of a generalized infection. The inflammatory tumor-like forms of mycotic infection termed mycetomas are rare in Europe but have been observed in America and in Africa. "Madura foot" is the most familiar example of a mycetoma.

In treatment, potassium iodide is to be preferred to all other drugs. One begins with 2 Gm. a day and increases the dose gradually until from 6 to 8 Gm. is given in twenty-four hours over a prolonged period, with intervals of from eight to ten days. Intravenous injection of aqueous solution of iodine has also been employed. Potassium iodide is especially efficacious in infections due to *Actinomyces* and *Sporothrix*. Local treatment must never be overlooked. This includes dilute solution of sodium hypochlorite, methylthionine chloride, aqueous solution of iodine, ultraviolet rays and roentgen treatment. In all bone cases, thorough eradication of the foci by operative measures should be carried out and supplemented by general treatment.

In the discussion, Allenbach reported nine personal cases observed during a period of five years. In all, the bone localization was the first clinical evidence of infection. The diagnosis could be made only as the result of the roentgen examination.

Lombard of Algiers had seen only four cases in twenty-five years. He was inclined to doubt the etiologic role of the various forms of mycoses and believed they were often only of a secondary character.

VOLKMANN'S CONTRACTURE

Massart of Paris read a paper on Volkmann's contracture. He maintained that such an ischemic contracture followed supracondylar fracture of the humerus more frequently than fracture of one or both bones of the forearm. It was formerly believed that interference with the circulation as the result of too tight a dressing was the chief factor in the etiology. Frequently such a cause is not to be found. At present the principal part is played by a extensive hemorrhagic infiltration of the involved muscles, which interferes with the return circula-

tion. This has been proved by the rapid relief of incipient symptoms of a Volkmann contracture in a case reported by Moulouguet and Senegaux, following incision of the aponeurosis. Intramuscular hemorrhages without fractures have been observed in hemophilic patients which gave rise to typical Volkmann contracture symptoms. The circulatory disturbances observed at the onset of this clinical entity, such as modification of the radial pulse and difference in the oscillometric curves of the two extremities, also verify this hypothesis. The sub-aponeurotic intramuscular serosanguinolent effusion is due to a blocked circulation and resembles the hemorrhagic infarcts observed in the lungs. The muscular changes are really circumscribed aseptic necroses of ischemic origin rather than a retractile myositis.

As to treatment, surgical measures should be applied as early as possible. They include incision of the aponeurosis and at the same time reduction of the fracture and inspection of the nerve trunks, peribrachial sympathectomy, in early cases only, and ligation of the brachial artery if the latter has been injured or is thrombosed. The early period having passed, extension methods give perhaps the best results. Other not generally accepted methods are resection of the radius and ulna, and disinsertion of the flexors and pronators from their attachments to the humerus, radius and ulna.

Lombard of Algiers reported a case in which sympathectomy of the brachial artery had been followed by complete disappearance of the Volkmann contracture symptoms in a boy of 12. The child could use his hand well, but the muscular force of the forearm was still below normal and atrophy persisted.

Froehlich of Nancy maintained that a plaster or splint dressing too tightly applied still must be considered as the principal cause of Volkmann's contracture in cases of fractures of the forearm and lower end of the humerus. He had reexamined seventeen patients and found this to be true of fifteen. The only surgical treatment was a resection of the radius and ulna.

Tavernier believed that the prognosis of the more advanced cases was not very promising. In late cases, resection of the wrist is indicated rather than that of the bones of the forearm.

Billet of Lille reported a case of immediate but only transitory (five days) improvement following a peribrachial sympathectomy. In a typical case without fracture occurring in a hemophilic patient the Volkmann contracture had disappeared spontaneously. It is advisable in general in cases of fracture of the elbow and forearm, to wait several days before attempting a reduction.

Meeting of the Therapeutic Union

A large number of foreign and French members of the Therapeutic Union met at Paris October 9. The president is Prof. M. Loeper of Paris. The first paper was on the "Quinine Salts in Cardiac Disease" by Professor Pelzi of Milan, who has found that quinidine is the only drug which can establish a normal rhythm in complete arrhythmia due to auricular fibrillation. Quinine is preferable to quinidine in the treatment of extrasystole and in paroxysmal tachycardia. In the former, quinine ought to be given orally but in paroxysmal tachycardia neither quinine or quinidine is efficacious if given orally. Quinine is especially indicated in cardiac conditions in nervous individuals without organic lesions in whom the vegetative nervous system functions so badly that there is a resultant disturbance of the cardiac rhythm. These are the individuals to whom the cardiologist has applied the terms "unstable with palpitation, irritable or hyperkemic hearts" like those seen following the World War. Professor Clerc and also Professor Pende have demonstrated the sedative action of quinine on the vagus in paralyzing the bulbar center and its action as a regulator. It acts also on the sympathetic nervous system hence its great value in neuropathic conditions of the heart.

Pende of Genoa, Bürgi of Brussels, Decourt of Paris and Delherm of Paris took part in a symposium on viscerospasm. Pende stated that a large number of conditions might give rise to viscerospasm. He mentioned hyperalkalosis, hypocalcemia, hyperphosphatemia, hyperpotassemia, parasympathetic predominance, predominance of parasympathicotonic hormones (acetylcholine, insulin, thymic and splenic hormones, solution of pituitary) or insufficiency of the sympathicotonic hormones (epinephrine, parathyroid extract).

The treatment of all viscerospasm symptoms should be to raise the calcium ion content of the blood, to diminish the alkaline phosphates of the blood and alkalosis in general, especially if one is able to demonstrate a diminished hydrogen ion concentration and an increase in the alkali reserve. The diet should include, as a base, foods with little potassium (oatmeal, milk, meats, fish, eggs, fats and cheese, all of which contain much calcium). As drugs, hydrochloride or phosphoric acid and ammonium, potassium or calcium chloride can be ordered. Among the endocrine products, epinephrine or parathyroid extract is to be preferred. Care must be used in attempting to correct the neurovegetative atonicity with such drugs as atropine or belladonna, which have a direct action on the neurovegetative system.

Bürgi read a paper on the spasmogenic substances and their antagonists. Pilocarpine, acetylcholine, physostigmine and the choline group can, through the agency of the parasympathetic system, give rise to spasms in the nonstriated muscle fibers of the stomach, intestine, uterus and bronchi. The choline derivatives dilate the blood vessels. Especially acetylcholine and its derivatives combat intestinal atony and blood vessel spasm. Lead has a spasmogenic action on the intestine, and barium chloride excites its muscle fibers. Epinephrine and ephedrine derivatives increase the tonus of the sympathetic nervous system and diminish intestinal spasm, but they contract the arteries of the uterus. Atropine and papaverine paralyze the nonstriated muscle fibers. Morphine is spasmogenic for the stomach but paralyzes intestinal peristalsis. The medical treatment of viscerospasm was discussed by Decourt. Every case requires special study before medication is begun. The available drugs can be placed in three groups: (1) those which are physiologic, such as calcium, magnesium, acids and the hormones, (2) the antispasmodic alkaloids, and (3) those acting reflexly or on the psychic centers. A local irritation in the viscus itself acts on the sensory nerve endings and by means of a reflex arc of variable length stimulates the motor element of the visceral spasm. One should always attempt to determine the underlying cause (sensory) of such a reflex arc. At times the spasm seems out of all proportion to the sensory cause, thus indicating an abnormal reactivity of the nervous system, as in asthma and spasmodic colitis. One is forced in some cases to ascribe the spasm to a veritable "diathesis" for which a sort of desensitization is necessary.

Ectopic Spleen with Torsion of Pedicle

At the July 10 meeting of the Société de chirurgie, Desplas reported the case of a woman aged 23, with a negative previous history, who had sudden severe colicky abdominal pain accompanied by metrorrhagia. Bimanual vaginal examination revealed an oval tender, mobile mass in the culdesac of Douglas to the left of the median line. A diagnosis of twisted pedicle of an ovarian cyst was made and a laparotomy was performed. This revealed that the mass was a large spleen presenting a threefold torsion of its long pedicle. On removal, section of the spleen disclosed little evidence of interference with its blood supply. Just before this attack the patient had passed through an apparently normal pregnancy, but a slow engagement of the head had been noted during the first stage of labor. The torsion of the splenic pedicle began

six days before the operation. In spite of this prolonged anemia, no very marked changes were to be found in the parenchyma. In the discussion, a similar case was cited in which Pean had operated in 1867. Gregoire reported a case similar to the case of Desplas. Faure also added a case in a man, the spleen being found in the rectovesical pouch. In his case there was no torsion of the pedicle. Mondor stated that he had been able to find reports of six cases like that of Desplas. It was easy to make such a mistake in diagnosis, especially when the ectopic spleen was an accessory one.

The Discovery of Syphilis

A short time ago, Haberling, professor of the history of medicine in Dusseldorf, discussed the question of the discovery of syphilis. In the last decade of the fifteenth century, which is replete with significant historical events as is scarcely another decade in the world's history, syphilis as a distinct disease entity first attracted attention. Astrologic interpretations having called attention to a sexual plague that would spring up in this decade, all Germany, through the blasphemy edict that was promulgated at Worms Aug. 7, 1495, became acquainted with the fact that a previously unknown disease called "die bosen Blattern," or virulent smallpox, had been sent down to earth as a punishment from heaven. In reality, as Haberling demonstrated, the disease was not new at that time but had been known for many years among the so-called wundärzte, by whom it was treated with mercury. Haberling also pointed out that in spite of the comprehensive research of Sudhoff, the fable of the American origin of syphilis still hobbles up even in studies apparently undertaken seriously. In Haberling's opinion this fable is connected with the then growing trade in guaiacum wood from which huge profits were realized. To strengthen the public faith in the efficacy of this wood, the absolutely groundless tales of the transmission of syphilis by the natives of Haiti to the sailors of Columbus were invented, a full generation after the discovery of America. Likewise the account of a devastating epidemic of syphilis in the vicinity of Naples and in German regions was a pure fabrication. Haberling pointed out also that, according to the researches of Sticker, along with the term "lepra vera," again and again one finds in the writings of the physicians of the middle ages the expression "lepra spuria" which, in contradistinction to lepra vera did not require isolation and was curable. This lepra spuria to which, in course of time, many other names were assigned, was doubtless syphilis, which, simultaneously with leprosy, was brought in from the Orient by persons returning from the crusades.

Sterile Marriages

In view of the attitude of the present German government in promoting an increase of the population, the question of sterile marriages is fraught with interest. Professor Eymmer, ordinarius in gynecology at the University of Munich, who discussed this subject before the Munich Medical Society, stressed most emphatically that any attempt to discover the cause in a given case presupposes a careful examination of both partners even though the wife should present pronounced abnormalities.

Causes of marital sterility traceable to the wife may be based on anomalies of any of the many portions of the genital canal. In addition, there are general, and even psychic, causes of sterility. Of less importance are inflammations of the vulva, tumor formations of the labia majora and the labia minora, and a rigid hymen. Vaginism as a psychic reflex requires mental treatment. There is no doubt that retroflexion of the

uterus may cause sterility. Considerable importance attaches to the observation that after long continued use of inserts and anticonceptional lavages, and also after induced abortion, sterility often intervenes. Nonpatency of the fallopian tube is an important factor from a purely numerical point of view. In bilateral closure of the tubes the prospects of successful treatment are very poor. Roentgen stimulative treatment is absolutely rejected by reason of the undesired effects often observed and because of possible injury to the germinal plasma. Sterility associated with disturbances of other endosecretory glands is always traceable to ovarian dysfunction accompanying these glandular disturbances. Of especial importance in this connection are the hypophyseal disorders. It is the opinion of Professor Eymmer that occasionally the causes of sterility lie in the general mode of living or in the misuse of medicines and luxury articles (tobacco).

Reduction in Industrial Accidents

According to investigations instituted by Oberregierungsrat Wicke, a general reduction in the number of accidents to German workmen is observed. According to the figures published by the industrial unions, conditions over the period 1929-1934 were as shown in the adjacent table. This obser-

Industrial Accidents in Germany 1929-1934

| Year | Number of Registered Full Time Workmen | Total Number of Workmen Compensated the First Time for Accident | Number of Compensated Accidents per Thousand Full Time Workmen | Number of Fatal Accidents | |
|------|--|---|--|---------------------------|--------------------------------|
| | | | | Totals | Per Thousand Full Time Workmen |
| 1929 | 10,770,361 | 66,404 | 6.17 | 4,913 | 0.46 |
| 1930 | 9,984,123 | 61,965 | 6.21 | 4,476 | 0.45 |
| 1931 | 8,394,347 | 47,369 | 5.64 | 3,221 | 0.38 |
| 1932 | 7,153,270 | 27,672 | 3.87 | 2,311 | 0.32 |
| 1933 | 7,738,697 | 24,139 | 3.12 | 2,402 | 0.31 |
| 1934 | 9,413,493 | 24,394 | 2.59 | 2,317 | 0.25 |

vation is the more surprising when one considers how many among those workmen recently put to work have, through enforced idleness, become disaccustomed to work. Wicke holds that this reduction in the number of accidents is ascribable particularly to the indefatigable accident prevention campaign that has been waged in recent years. In the building trades it has been established that, in 1932, 7.87 per thousand full time workmen suffered their first compensated accident and that 0.55 of these accidents (per thousand workmen) proved fatal. In 1933 the corresponding figures were 5.19 and 0.43, in 1934 4.80 and 0.45. In 1932 in underground operations 15.48 per thousand full-time workmen suffered their first compensated accident and 0.92 of these accidents (per thousand workmen) proved fatal. The corresponding figures for 1934 were 5.75 and 0.66. During the first seven months of 1935 there was a still further decrease in the number of accidents.

Seventy-Fifth Anniversary of the Founding of the Berlin Medical Society

On October 31 the Berliner Medizinische Gesellschaft will celebrate its seventy-fifth anniversary. The society at its founding was an amalgamation of two societies, the Gesellschaft für wissenschaftliche Medizin and the Verein Berliner Aerzte. Its first president was the surgeon Langenbeck, who was succeeded by Graefe, Virchow, von Bergmann and many others whose names are well known. Since 1915 the society, in affiliation with the Deutsche Gesellschaft für Chirurgie, has had a new building of its own—the Langenbeck-Virchow Haus. For many years the Berliner Medizinische Gesellschaft exerted an important influence over medicine in general, which was far beyond its local significance. In recent years, because of the disturbing political events, the attendance has fallen off considerably.

BUDAPEST

(From Our Regular Correspondent)

Nov 1, 1935

The International Dermatologic Congress at Budapest

The work of Prof Louis Nékam and the Hungarian organization committee stimulated great interest in the ninth International Dermatologic Congress, held in Budapest September 13-21. Of more than a thousand members assembled here, about eight hundred were foreigners. Official representatives were present from twenty-seven countries. Fifty-seven universities and more than sixty scientific societies and institutions sent delegates. The European universities two universities of Argentina, three universities of the United States, and universities of Egypt, Japan and China sent official representatives.

The opening of the congress took place in the magnificent cupola hall of the parliament building in the presence of a huge audience including representatives of the Hungarian government. The opening address was made by Professor Nékam. Professor Zieler of Würzburg greeted the congress on behalf of all nations. After the opening speeches the board of the Budapest Pázmány Peter University of Sciences awarded to Prof Jean Darier of Paris, president of the International Dermatologic League, an honorary diploma. M. Horthy regent of Hungary, received the members of the congress at 5 o'clock tea in the royal castle, while in the evening the government received the members in the gala hall of the ministry of internal affairs.

The scientific work began next day. The international permanent committee of eleven met under the presidency of Professor Darier and resolved to reduce the membership fee of the International Dermatologic League to 25 Swiss centimes annually. The permanent committee has been supplemented by new members: Lesczinsky of Lemberg, Arzt of Vienna, Zieler of Würzburg and Harold N. Cole of Cleveland. The committee reported that the Spanish government had sent an invitation to hold the next congress in Madrid, which the congress unanimously accepted.

Under the presidency of Rille of Leipzig the terminology committee resolved to preserve the old classic etiologic denominations and if this is not feasible, the pathogenesis should be reflected in the terms used.

The classification committee under the presidency of Howard Fox of New York set as an aim a grouping of diseases on an etiologic and pathologic basis. The committee agreed to observe three points of view in the matter of classification: clinical symptoms, tissue anomalies and etiology.

Under the presidency of Gougerot of Paris the reform of teaching was discussed. It was agreed that dermatology should be given at the universities four hours a week while specialty training should require three years of special study, with at least one of the years spent in a university clinic. The exchange of assistants and special dermatologic graduate courses for qualified dermatologists were suggested.

Under the presidency of Graham Little of London a committee discussed questions of practice. It objected to further socialization of medicine. The committee considered the compulsory notification of venereal diseases and professional secrecy, which, it decided, should be defended unless its breach is required by the law.

A committee under the presidency of Tomassi of Palermo resolved that a new institution, the international exchange center should be established. For five years the seat of this will be the dermatologic clinic of Budapest. The purpose of this exchange center is to supply institutes and also private physicians with scientific and analytical material the acquisition of which is difficult. There will be exchange of microscopic preparations, bacterial cultures, vaccines, photographs and reprints. The center will forward leaflets on scientific subjects to its members.

The idea was received with enthusiastic approval. The scientific subjects discussed concerned venereal diseases, skin tuberculosis, diseases conveyed to men from animals, medical examination before marriage, sex education and antivenereal institutes. Also therapeutic methods and preventive measures were discussed, and the compulsory examination of grammar school children, suggested by Professor Neuber of Debreczin, was approved.

At the conference on skin tuberculosis, under the presidency of Lomholt of Hague, it was resolved to collect statistics on lupus patients and to establish lupus homes, and to study the social conditions of lupus patients and methods by which poor patients can be adequately treated and placed in institutes where they can carry on some occupation. It was deemed desirable that an international lupus home should be organized. To carry out this plan a special committee was appointed.

The president of the conference dealing with industrial skin diseases was Oppenheim of Vienna. The conference dealt with the compilation of a list of poisons, clinical instruction on industrial diseases, and the problems of insurance and indemnity.

The conference on comparative dermatology, cooperated with veterinary surgeons under the presidency of Marel of Budapest, discussing diseases of animal origin—erysipeloid, bird tuberculosis, foot and mouth disease, anthrax, malleus, brucellosis, tularemia, and fungous diseases of animal origin. Gottron of Berlin read a paper on the bacteriology and epidemiology of erysipeloid. Balogh exhibited histologic slides of eight cases of glanders observed by him.

The scientific papers were presented in four spacious halls of the Redout. Professor Darier outlined the fifty years of the development of dermatology, through the morphologic etiologic and biologic development stages. Sabouraud of Paris summarized the development of mycology. Riecke of Göttingen discussed the relation of dermatology to the general medical sciences. In the symposium on the functions of the skin, the speaker dwelt on the skin as a defensive organ. Darier, Civatte and Tzank of Paris stated that in case of external influences the skin reacts either defensively or passively: it takes up the entering substance and assimilates it (immunity) or defends itself with an inflammation (intolerance). Pasini of Milan discussed the temperature of the skin, abnormal dermographism and the influence of hemoglobin and porphyrin on skin processes. Milian of Paris discussed the dermatoses produced in connection with the defensive action of the skin. Hegler of Hamburg explained the connection between the skin and the internal organs in infectious diseases. Lesczinsky of Lemberg interpreted the connection between the skin and the sexual organs. Desaux of Paris called attention to the connection between the skin and the gastro-intestinal system. Brack of Basle emphasized the role of the vegetative system in the origin of itching.

In the symposium on allergy, Stühmer of Freiburg dealt with allergy in syphilitic cases. W. Jadassohn of Zurich made known the mechanism of allergic testing. Geber of Budapest described a method of desensitization. Mouriquand Gate of Lyons discussed the importance of metabolic disturbances in the causation of skin diseases. Spillmann of Nancy explained the role of the endocrine glands in the origin of skin diseases.

In the symposium on skin diseases produced by external causes, Sir Graham Little sketched the English conditions, reading statistics on chemical and other substances causing skin disorders. Brill of Rostock called attention to the importance of climate, race and geographic position.

In the symposium on filtrable viruses variola, varicella, tuberculosis, herpes and papilloma were discussed. Balogh of Budapest reported the results of extensive investigations of cases of varicella and found pathologic changes in the spinal ganglions, which he regards as histologic group reactions. Lavre-Gate of Lyons stated that it is probable that the bacillus of tuberculosis possesses also an ultravirus form. Baló of Budapest discussed the etiology of senile warts and papillomas, which he believes

are caused by filtrable viruses Urbach of Vienna gave an account of his experiments on pemphigus, which he believes is caused by a filtrable virus Several members of the congress took a different view

In the symposium on the pathology of tuberculosis, Lange of Berlin pointed out that the theories with regard to the developmental cycles and filtrable forms of the tubercle bacillus have not been sufficiently confirmed. Gougerot of Paris read a paper on the local action of the tubercle bacillus, the tuberculi, the local defenses of the skin and the role of antibodies formed in the skin

In the symposium on syphilis, Mulzer of Hamburg read a paper on the nonspecific treatment of syphilis Cole of Cleveland and his fellow dermatologists reported experiences gained in five American clinics An examination of 6,253 cases of late syphilis was made to ascertain how far antisyphilitic treatment is apt to check the evolution of cardiovascular and central nervous system manifestations Pinard of Paris reviewed the literature on malaria and fever therapy The same topic was the subject of a paper by Arzt of Vienna. Hilgermann read a treatise on the treatment of syphilis with vaccine prepared from inactivated spirochetes The results as yet are not encouraging Zieler of Würzburg summarized the criteria that determine the cure of syphilis

Many papers were read on miscellaneous subjects Von Berde of Szegedin stated that rat pellagra is not identical with human pellagra and that the latter is not caused by the lack of vitamin B but is a genuine infectious disease, which occurs only in association with some nutritional and digestive disturbance Nicolau of Bucharest spoke on inguinal lymphogranulomatosis Reiss of Shanghai read a paper on the tubercloid form of lepra as observed in China Pearce of New York made known his experiences with experimental syphilis The number of papers presented in this group exceeded 400 of which fifty-six were read by Hungarians

An interesting part of the scientific meetings was the demonstration of slides of microscopic preparations Jame of Paris projected a film illustrating the treatment of gonorrhea in the French army Györkovacs of the French Congo presented a film on tropical skin diseases and the public health institutions of the Congo region Schereschewsky of Paris demonstrated the morphology and motion of *Spirochaeta pallida* in experimental and human syphilis, together with its response to chemotherapy

The scientific work was supplemented by a scientific exhibition The historical section comprised the valuable library of the Budapest dermatologic clinic, including a great number of incunabula, codexes and collected edicts Faludy's precious collection of medical plaquettes had many admirers, likewise the ancient atlases of the Parisian St Louis Hospital, a collection of the photographs of prominent dermatologists, and old medical prescriptions The Hungarian National Museum lent many objects, among them a collection of faience pots used in pharmacists' shops in the sixteenth, seventeenth and eighteenth centuries Another section comprised the wax models of parasites causing skin diseases, moulages, several hundred histologic figures, insects, plants, wood substances causing skin disorders, cultures of bacteria pathogenic to the skin, and charts displaying the frequency of various skin diseases Much interest was shown in the exhibition of fungi, compiled by Ballagi, the first to collect almost all varieties of fungi causing skin diseases Cultures were exhibited from all parts of the globe, and keeping them alive was the duty of the Budapest dermatologic clinic. The transinoculated stocks stood at the disposal of all members of the congress In fact, this was the first function of the central exchange On the last day, 140 patients were exhibited

During the congress a gala performance was given at the Royal Opera members were entertained at an evening party in the Alpine village at a Budapest park, and a banquet was given at the Hotel Gellert

Marriages

HOWARD Q L LITTLE, Gibsonville, N C., to Miss Elizabeth Jordan of Smithfield at Kernersville, in September

WILLIAM HUSTON TANKSLEY JR., Nashville, Tenn., to Miss Billie Barringer of Sumter, S C., October 2

FRANK KIMZEY JUSTICE, Clayton, Ga., to Miss Katherine S Miller of Murphy, N C., October 19

SAMUEL WEISSROSS, Pocatello, Idaho, to Miss Evelyn Vera Maver of Los Angeles, December 8

WILLIAM H KRAUSE, Windsor Vt., to Miss Madeline Kel liher in Amenia, N Y, October 10

HAROLD T LARSEN, Fort Dodge, Iowa, to Miss Katherine Kumpf of Los Angeles, October 7

LOUIS SCHNEIDER, New York, to Miss Lilian Blass of Mount Vernon, N Y, November 28

MARTIN PATMOS, Kalamazoo, Mich., to Miss Alice Eleanor Brown of Detroit, June 7

HAROLD E O'NEAL, Tipton, Iowa, to Miss Elsie Maddox of Sedalia, Mo., October 13

HOWARD G BEATTY, Creston, Iowa, to Miss Helen Maneely of Afton, October 17

Deaths

William Perry Northrup, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1878, an Affiliate Fellow of the American Medical Association, instructor of Greek, Knox College, Galesburg, Ill., 1872-1876, adjunct professor of pediatrics, 1893-1896, professor, 1896-1919, and since 1919 emeritus professor of pediatrics, University and Bellevue Hospital Medical College a founder and past president of the American Pediatric Society, for many years on the staff of the Presbyterian Hospital, New York Foundling Hospital, Willard Parker Hospital and the hospitals of the New York Health Department, the Babies' Hospital, Newark, N J, and the State Orthopedic Hospital, West Haverstraw, N Y, also played an important part in Dr O'Dwyer's development of the treatment of diphtheria by intubation, American editor of "Ashley and Wright's Diseases of Children" in 1900, and "Nothnagel's Encyclopedia of Practical Medicine," American edition, volume 4, in 1902, aged 84, died, November 20

Charles Percy Noble, Radnor, Pa., University of Maryland School of Medicine, Baltimore, 1884, at one time clinical professor of gynecology, Woman's Medical College of Pennsylvania, Philadelphia, at various times on the staffs of the Chester County Hospital, West Chester, Kensington Hospital for Women, Stetson Hospital, Philadelphia Lying-in Charity Hospital and the Woman's Hospital, Philadelphia, co-editor with Howard A Kelly and one of the authors of the "Kelly Noble Gynecology and Abdominal Surgery" in two volumes, corresponding member of Die Gynäkologische Gesellschaft in München, aged 72, died, November 21

Hugo Albert Kiefer of Los Angeles University of Pennsylvania Department of Medicine, Philadelphia, 1897, formerly adjunct professor and assistant professor in ophthalmology, University of California Los Angeles Medical Department, member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society, fellow of the American College of Surgeons, on the visiting staff of the Hollywood Clara Barton Memorial Hospital, aged 65, died, October 26, in Cedars of Lebanon Hospital

Thomas Herbert Bell, Winnipeg, Manit., Canada, Trinity Medical College, Toronto, Ont., 1896, M R C S., England, and L R C P., London, 1897, professor of ophthalmology, University of Manitoba Faculty of Medicine, fellow of the American College of Surgeons, aged 63, on the staff of the Winnipeg General Hospital, where he died, November 28, of cerebral embolism and thrombosis of the right leg

Douglas Bissell of New York, University of Maryland School of Medicine, Baltimore, 1888 member of the American Gynecological Society, one of the founders and fellow of the American College of Surgeons, past president of the New York Obstetrical Society, surgeon to the Woman's Hospital, 1910-1929, aged 71, died, December 3, of cerebral hemorrhage

Joseph Albert McGuire, Norton Va., University of Virginia Department of Medicine, Charlottesville, 1900 member of the Medical Society of Virginia, past president of the Wise

County Medical Society, member of the state board of health, formerly medical director of the Norton Hospital, aged 59, died October 25, of cerebral hemorrhage.

William Burdick Wells ♂ Riverside, Calif., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901, formerly health officer of Riverside City and Riverside County and secretary of the Health Officers' Section of the League of California Municipalities, aged 60, died, November 1

Richard Root Rupert, South Bend, Ind., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912, member of the American Association of Anatomists, ship surgeon to the steamship *American Trader* aged 53, died, October 16, of cerebral hemorrhage, while in England

Warren Lynnford Duffield ♂ Brooklyn, Long Island College Hospital, Brooklyn, 1898 fellow of the American College of Surgeons, senior surgeon to St John's Hospital consulting surgeon to the Methodist Episcopal Church Home, Brooklyn, and the Southside Hospital, Bayshore, aged 60, died, November 21

Emmett Patrick Whalen, Indiana, Pa. St Louis University School of Medicine, 1932, member of the Medical Society of the State of Pennsylvania aged 28, on the staff of the Indiana Hospital, where he died, November 8, of peritonitis, following a perforated gastric ulcer

Daniel Thompson Boger, Monroe, N. C., North Carolina Medical College, Davidson, 1906 member of the Medical Society of the State of North Carolina president of the Union County Medical Society, aged 67, died, December 2, in a hospital at Charlotte

Samuel Mitchell Wagaman, Hagerstown Md., University of Pennsylvania Department of Medicine, Philadelphia 1901 formerly county health officer, at one time on the staff of the Washington County Hospital, aged 62 died, November 8, of heart disease.

Ida Mary F. Alexander, Lansing Mich. University of Minnesota Medical School, Minneapolis 1908, lecturer for the state health department on child and maternal hygiene, aged 58 was found dead in her automobile near Lake City, October 23

James Joseph King ♂ New York, University of Louisville (Ky.) Medical Department, 1907 member of the American Academy of Ophthalmology and Oto-Laryngology, formerly on the staff of the French Hospital, aged 53 died, November 29

William Franklin Keller ♂ Sioux Falls S. D., University of Nashville (Tenn.) Medical Department, 1897, served during the World War for twenty years president of the city health department, state prison physician, aged 71, died in October

Norvel William Jarvis, Festus, Mo. St. Louis University School of Medicine, 1904 member of the Missouri State Medical Association, past president of the Jefferson County Medical Society, aged 55, died, October 23, of cerebral hemorrhage

Charles Felice Tommasi, Newark, N. J. Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy 1899, member of the Medical Society of New Jersey aged 67 died October 29, of coronary thrombosis and bilateral pyonephrosis

Ogilvia Curtis Ricksecker ♂ Wilmot Ohio, Ohio Medical University, Columbus 1897, also a druggist past president of the Stark County Medical Society formerly county health officer, aged 60 died, October 22, of cerebral hemorrhage

Harry Albert Bennett, Battle Creek, Mich. Eclectic Medical College, Cincinnati, 1915, on the staff of the American Legion Hospital aged 52 died, October 26 in the Leila Memorial Hospital of teratoma of the testicle

Oscar Edwin McHenry, Blue Creek Ohio Medical College of Ohio Cincinnati 1903 member of the Ohio State Medical Association, for many years member of the board of education aged 68 died, October 26

Archibald Carlton Weaver, Santa Monica, Calif. Western Reserve University Medical Department Cleveland, 1911, member of the California Medical Association formerly police surgeon aged 49 died, October 23

George B. Gesner ♂ Marshall Mich. Trinity Medical College Toronto Ont. Canada, 1899 for many years member of the board of education on the staff of the Oaklawn Hospital aged 64, died October 27

Joseph Leslie Pyle, Chester W. Va. Keokuk (Iowa) Medical College, 1896 formerly mayor of Chester at one time president of the Public Health Council, aged 68 died suddenly, October 23 of heart disease

Henry Finlay Hyndman ♂ Wichita, Kan., University of Kansas School of Medicine Kansas City 1910 past president

of the Sedgwick County Medical Society, aged 49, died, October 31, of diabetes mellitus

Paul Williams Sweet ♂ Centralia, Wash. Jefferson Medical College of Philadelphia, 1908, medical director of St Luke's Hospital and Sweet Clinic, aged 56, died, October 22, of cerebral hemorrhage.

Cortes Holiday Wheeler, Portland, Ore., Medical College of Ohio, Cincinnati, 1875, member of the Oregon State Medical Society formerly health officer of Portland, aged 86, died, October 31

Horace Clinton Whisler, Smithfield, W. Va., University of the South Medical Department Sewanee, Tenn. 1898, aged 76 died, October 14, in a hospital at Laurel, Md., of heart disease

John Gordon McGuire, Chicago, Chicago College of Medicine and Surgery, 1911, also a minister, aged 62, died, November 30, in the Cook County Hospital, of cerebral hemorrhage

Edward F. Beall, San Marcos, Texas, University of Louisiana Medical Department, New Orleans, 1883, member of the State Medical Association of Texas, aged 71, died, October 6

William Abraham Berendsohn, Brooklyn, Long Island College Hospital, Brooklyn, 1889, member of the Medical Society of the State of New York aged 67, died, October 7

Thomas A. Cahill, Chicago, Chicago College of Medicine and Surgery, Medical Department of Valparaiso University, 1904 aged 56 died, September 8, of carcinoma of the lung

Samuel Melvin Harpe, Calhoun, Ga., University of Georgia Medical Department, Augusta, 1884, member of the Medical Association of Georgia, aged 72, died, October 27

William Alexander Thomson Robertson, Ponca City, Okla. McGill University Faculty of Medicine, Montreal, Que., Canada 1896, aged 66, died, October 26

James Thomas Moon, Miami Okla., Eclectic Medical College, Cincinnati, 1922, member of the Oklahoma State Medical Association, aged 49, died, October 20

John Edler Knipfel, Barkerville, B. C., Canada, University of Toronto Faculty of Medicine, 1905, aged 59, died, September 30, in Wells, of acute myocarditis

John C. Swan, Marietta, Ohio, Jefferson Medical College of Philadelphia, 1876, aged 81, died, October 20, in the Marietta Memorial Hospital, of pneumonia

Donald James Strohm, Audubon, N. J., University of Pennsylvania School of Medicine, Philadelphia, 1931, aged 30, died December 3, of encephalitis

Harrison Morgan Brown ♂ Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1904, aged 61, died, October 25, of cerebral hemorrhage

Charles Henry Glidden, Fort Pierce, Fla., Hahnemann Medical College of Philadelphia, 1876, aged 82, died, November 21, of cardiorenal disease

Orange H. Thomas, Fremont, Ohio, Medical College of Ohio, Cincinnati, 1882, for many years county health officer, aged 76 died October 19

Charles Edward Wingfield Jr., Athens, Ga. Meharry Medical College Nashville, Tenn. 1929, aged 31, died, October 28, in a local hospital

Robert Clarke Boyle, Vancouver, B. C., Canada, Manitoba Medical College, Winnipeg 1892, aged 66, died, November 18 of angina pectoris

David Douglas Steiner, Quincy, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1886, aged 75, died, September 27, of cerebral hemorrhage

Orizabor Burnett Fritch, Detroit, Michigan College of Medicine and Surgery, Detroit, 1904, aged 60, died, October 27, of heart disease

Crawford Le Roi Thompson, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1896, aged 60, died, October 14

John MacRae, Los Angeles, University of Pennsylvania Department of Medicine, Philadelphia, 1884, aged 73, died, October 15

Jefferson D. Magee, Abilene, Texas Louisville (Ky.) Medical College, 1886, aged 74, died October 11, of lobar pneumonia

Jennie Baker, Chicago College of Medicine and Surgery, Chicago, 1908, aged 72, died, September 28 of cerebral hemorrhage

Augustus Baton Kehrner, Philadelphia, Hahnemann Medical College of Philadelphia, 1880, aged 79 died, October 25

James Beard, San Francisco California Medical College, San Francisco, 1899, aged 77, died, October 1

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner,* (3) the composition, (4) the type of nostrum (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Warm Springs Crystal Compound—Warm Springs Crystal Sales Co. Warm Springs Ga. Composition Essentially Glauber's salt. For stomach disorders. Fraudulent therapeutic claims.—[N J 22613 February 1935]

Hayward's Preparation—Hayward Remedy Co. Inc. New York. Composition Essentially an iodide with alcohol and water. For asthma, hay fever and bronchial catarrh. Fraudulent therapeutic claims.—[N J 22621 February 1935]

Leonard's Mexico Barbed Wire Liniment—Mrs. Harry Leonard Hutchinson Kan. Composition Essentially kerosene, linseed oil and tar oil. For lung troubles, diphtheria, bronchitis, tonsillitis, etc. Fraudulent therapeutic claims.—[N J 22633 February 1935]

Pneumoseptin—Virginia Carolina Medical Co. Roanoke Va. Composition Essentially camphor, wintergreen, eucalyptol and lard. For congestion, inflammation, etc. Fraudulent therapeutic claims.—[N J 22634 February 1935]

Husbands' Calcined Magnesia—Husbands' Magnesia Co. Inc. Philadelphia. Composition Essentially magnesium oxide. For indigestion, dyspepsia, rheumatism, etc. Fraudulent therapeutic claims.—[N J 22636 February 1935]

Germol—Paris Chemical Co. Huntingdon Tenn. Composition A dilute solution of hydrochloric acid in water, colored red. For stomach, liver and kidney troubles, etc. Fraudulent therapeutic claims.—[N J 22637 February 1935]

Georgia Crystal Compound—Warm Springs Crystal Co. Warm Springs Ga. Composition Essentially Glauber's salt. For sour stomach, heartburn, hyperacidity, etc. Fraudulent therapeutic claims.—[N J 22638 February 1935]

Truth Brand White Pine Cough Syrup—Blackstone Mfg. Co. Newark N. J. Composition Essentially chloroform, tar, sugar and water with a small amount of inorganic salts. Fraudulent therapeutic claims.—[N J 22641 February 1935]

Echlone—Strong Cobb & Co. Cleveland. Composition Essentially plant drug extracts, alcohol, sugar and water. For chronic eczema, ulcers, boils, etc. Fraudulent therapeutic claims.—[N J 22642 February 1935]

Cysto Sedative—Strong Cobb & Co. Cleveland. Composition Essentially plant drug extracts, alcohol, sugar and water. For genito-urinary diseases. Fraudulent therapeutic claims.—[N J 22642 February 1935]

Kuhn's Ep Sum Pill—H. Dale Kuhn Laboratory, Shelby Ohio. Composition In each pill aloin, phenolphthalein (about ½ grain) and epsom salt (about 3 grains). For regulating bowels for headaches, neuralgia, etc. Fraudulent therapeutic claims.—[N J 22646 February 1935]

Epsaline Tablets—Cold Seal Products Co. Columbus Ohio. Composition In each tablet aloin, phenolphthalein (about ½ grain) and epsom salt (7½ grains). Alleged tasteless and concentrated substitute for epsom salt. False therapeutic claims.—[N J 22648 February 1935]

Katrolpine Antiseptic Nasal Jelly—Phoenix Drug Co. Newark N. J. Composition Chiefly benzocaine (3 per cent) and essential oils including menthol and camphor incorporated in fat. For hay fever, catarrh, sinus infections, etc. Fraudulent therapeutic claims.—[N J 22648 February 1935]

Parker's Treatment for Indigestion and Constipation—Parker Medicine Co. Cincinnati. Composition Essentially baking soda (42 per cent), starch and ginger, peppermint flavored. The Liver Tablets which were part of the treatment contained plant drug extracts including aloin and nuxvomica. Fraudulent therapeutic claims.—[N J 22653 February 1935]

Female Re Lax Lozenges—H. Will Elders, St. Joseph Mo. Composition Plant drug extracts including a laxative, ginger and belladonna, podophyllin and a strychnine compound coated with sugar and calcium carbonate and colored red. For laxative and tonic purposes. Fraudulent therapeutic claims.—[N J 22655 February 1935]

Sterillone—H. Will Elders, St. Joseph Mo. Composition Essentially plant drug extracts including hydrastis and a laxative with ferrous sulphate and arsenic trioxide. For sterility, etc. Fraudulent therapeutic claims.—[N J 22655 February 1935]

Servu Vaporizing Rub—Service Laboratories, St. Louis. Composition Essentially volatile oils such as wintergreen, camphor, menthol and eucalyptus with turpentine incorporated in petroleum and fat. For coughs, rheumatism, stiff neck, etc. Fraudulent therapeutic claims.—[N J 22661 February 1935]

Po Da Cro Bak Ake Kidney and Bladder Pills—Podacro Co. Inc. Morristown Tenn. Composition Juniper oil and methylene blue, coated with calcium carbonate. Fraudulent therapeutic claims.—[N J 22667 February 1935]

Buno Hair Medicine—Buno Co. Inc. Philadelphia. Composition Resorcin, brucine, perfume oils including bay with alcohol, water, a small amount of a fatty oil and yellow coloring. For dandruff, falling hair, eczema, etc. Fraudulent therapeutic claims.—[N J 22664 February 1935]

X E Ma—X E Ma Co. Milwaukee. Composition Essentially mercuric chloride, glycerin and water, colored red. For skin disorders including eczema, psoriasis, itch, dandruff, etc. Fraudulent therapeutic claims.—[N J 22666 February 1935]

Pioneer Crystals—Pioneer Crystal Co. Mineral Wells Texas. Composition Essentially dehydrated Glauber's salt (99.1 per cent) and a small amount of common salt. For Bright's disease, high blood pressure, arthritis, neuritis, etc. Fraudulent therapeutic claims.—[N J 22668 February 1935]

Dieto—Kent Drug Co. Brooklyn. Composition Partly dehydrated epsom salt, potassium sulphate and common salt. For reducing weight, maintaining youth and preventing various diseases induced by overweight. Fraudulent therapeutic claims.—[N J 22669 February 1935]

Clifton's Brazillian Oil—Clifton Drug Co. Girard Ill. Composition Essentially nitrobenzene and extract of red pepper dissolved in gasoline. For toothache, rheumatism, deafness, swollen glands and limbs, etc. Fraudulent therapeutic claims.—[N J 22670 February 1935]

Clifton's Brazillian Herb Tablets—Clifton Drug Co. Girard Ill. Composition Essentially ground plant drugs such as aloin, cascara sagrada, uva ursi, damiana and a pungent drug. For stomach, kidney and joint disorders, etc. Fraudulent therapeutic claims.—[N J 22670 February 1935]

Bon Vino Health Restorer—Bon Vino Products Inc. Buffalo. Composition Essentially plant drug extracts including a laxative with alcohol (about 20 per cent by volume) and water, mint flavored. Misbranded because not made in Poland as represented and because alcohol content was incorrectly declared misbranded further because of fraudulent therapeutic claims as a tonic, etc.—[N J 22674 February 1935]

Sanmetto—Od. Peacock, Sultan Co. St. Louis. Composition Plant drug extracts, alcohol and water. For genito-urinary disorders. Fraudulent therapeutic claims.—[N J 22955 April 1935]

R M B Powders—R M B Laboratories Inc. Seattle. Composition Essentially bismuth subnitrate and sugar. For stomach disorders including ulcers. Fraudulent therapeutic claims.—[N J 22957 April 1935]

Dismuke's Famous Mineral Crystals—Famous Mineral Water Co., Mineral Wells Texas. Composition Essentially Glauber's salt with small amounts of chlorides and magnesium compounds such as epsom salt. For stomach trouble, rheumatism, auto-intoxication, etc. Fraudulent therapeutic claims.—[N J 22956 April 1935]

Peerless Crystals—Peerless Mineral Water & Crystal Co. Mineral Wells Texas. Composition Essentially Glauber's salt with small amounts of common salt and epsom salt. For rheumatism, gout, stomach, kidney and bowel troubles, etc. Fraudulent therapeutic claims.—[N J 22958 April 1935]

Nuxferrone—John L. O'Bannon, Marissa Ill. Composition Essentially compounds of iron, manganese, calcium and potassium hypophosphites, quinine, peptone, extracts of plant drugs including nuxvomica and a laxative with alcohol, water and aromatics. For debility, anemia, etc. Fraudulent therapeutic claims.—[N J 22959 April 1935]

Re Cu Ma—Robinson Drug Co. Blytheville Ark. Composition Epsom salt, potassium iodide, plant drug extracts including licorice, aloin and podophyllin with glycerin, alcohol (8.6 per cent by volume) and water, flavored with anise and sweetened with saccharin. System purifier and tonic. Fraudulent therapeutic claims.—[N J 22980 April 1935]

Puratone—John L. O'Bannon, Milan Tenn. Composition Essentially plant drug extracts including licorice and a laxative such as cascara sagrada with alcohol (7.9 per cent by volume), glycerin and water. For stomach, liver, kidney, bowel and blood disorders. Fraudulent therapeutic claims.—[N J 22961 April 1935]

Kal—Makera of Kal, Los Angeles. Composition Essentially powdered rice, cocoa and dicalcium phosphate. For mineral deficiencies in diet. Fraudulent therapeutic claims.—[N J 22963 April 1935]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

ARTERIAL TENSION AND CARDIAC RESERVE

To the Editor.—What reliable and dependable authoritative part does blood pressure take in cardiac insufficiency? When the pulse pressure exceeds the diastolic pressure unless in aortic regurgitation is it not evident that the cardiac reserve is low and that myocardial safety is at stake? Is it not proper to warn such a patient of his weakness and advise against taxing his heart muscle by any strain—even a physician's duty to urge complete rest until the patient's physical condition improves? Is not myocardial weakness the stepping stone to cardiac failure and often overlooked until conditions become so bad that prolonged rest—even heroic measures—must be resorted to in order that normality may be regained? Are not dyspnea on slight exertion sleeping with the head elevated or even the stage of orthopnea edema of the extremities and hypertension with or without valvular murmur or pain all evidences of deficient cardiac reserve or a weak heart? There are many tests for myocardial deficiency listed in the literature but my experience has been that the Barach rule and Strassburger's rule both obtained by blood pressure readings prove valuable adjuncts in diagnosis the former to give the systolic diastolic rate index and the latter showing the efficiency of the heart as a pump or the blood pressure coefficient. The latter is shown in the example cited at the beginning of this letter wherein I refer to the high pulse pressure exceeding the diastolic pressure which would give over 50 per cent which normally should be between 20 and 40 per cent. Below 20 or over 40 per cent is considered myocardial inefficiency. As some may not be familiar with the Strassburger rule allow me to say that it is obtained by dividing the pulse pressure with two ciphers added by the systolic pressure and the result gives a percentage which should be within the limits mentioned (from 20 to 40 per cent). Posture and exercise tests also are coordinating proofs of heart efficiency all of which taken with the general history aided of course by the cardiogram when available confirms the fact of normal or weak heart muscle. May I ask your valuable experience as to the foregoing being reliable in drawing conclusions about the condition of the heart muscle?

M D District of Columbia

ANSWER.—The arterial tension is often a valuable guide to the status of the cardiac reserve. After all, it is primarily the cardiac force that maintains the arterial tension. Briefly, it may be said that the diastolic pressure is equivalent to the peripheral resistance to the circulation and that the systolic tension represents the cardiac force overcoming this resistance and propelling the blood. Therefore ignoring for the time being such factors as pulse volume and circulatory velocity one may consider the pulse pressure as an indirect index to the useful propulsive force of the heart. The arterial tension alone however does not tell the whole story and the pulse rate is of the greatest significance in evaluating the cardiac reserve as well as the results of physical examination.

The relationship of the pulse pressure to the diastolic pressure is not a fixed one and it is altered by a number of factors. For example as the diastolic tension rises in hypertensive arterial disease the pulse pressure increases more rapidly, with a competent heart. Maintenance of the diastolic pressure is certainly dependent on competence of the aortic valves in aortic regurgitation the pulse pressure is often extreme. Thyrotoxicosis, by increasing the cardiac output without much, if any, change in the peripheral resistance often results in a greatly increased pulse pressure. In these instances the diastolic tension is usually normal or slightly elevated whereas in the former example of aortic regurgitation it is almost invariably much reduced. In thyrotoxic tachycardia the rise in pulse pressure is proportionate to the elevation of the basal metabolic rate and increased cardiac volume output. In acute myocardial failure it is usual that the systolic tension and pulse pressure are reduced, and such reduction is of ominous prognostic import. The pulse pressure may be considered a rough measure of the stroke volume, which is ordinarily reduced in cardiac exhaustion. However, myocardial inadequacy may be associated with dilatation of the ventricle of such a degree that relative aortic regurgitation results with a consequent great increase in the pulse pressure. This increase is associated with a reduced diastolic tension. This exception to the general rule that with reduced myocardial strength the pulse pressure falls occurs most frequently in cases in which silent and asymptomatic calcification of the aortic valves has occurred, as described by Henry A. Christian (*Aortic Stenosis with Calcification of the Cusps* THE JOURNAL, July 18 1931 p 158) and by H M Margolis F O Ziellessen and A R Barnes (*Am Heart J* 6 349 [Feb] 1931).

The complaints and symptoms mentioned in the query are certainly evidences of reduced cardiac reserve and warrant the induction of rest. This is particularly the case if the pulse is

rapid. Hypertension is mentioned as one of the evidences of cardiac disease. This is really putting the cart before the horse cardiac disease is a consequence of hypertensive arterial disease and not vice versa. To evaluate fully the significance of the hypertension in such an instance, it is important to know not only the present levels but what the blood pressure was before the appearance of signs of myocardial inadequacy. The cardiac changes in hypertensive disease are divisible into three phases (1) the sthenic stage, in which the heart is amply compensated, the pulse is slow and the pulse pressure is increased proportionately more than the diastolic tension, with a good response to exertion, (2) the asthenic stage, which appears insidiously in an almost imperceptible transition from the sthenic phases and which is characterized by an increasingly rapid pulse a diminishing pulse pressure due to a fall in the systolic levels and the induction of dyspnea by lesser degrees of effort and (3) frank myocardial decompensation with its attendant fall in the systolic tension and the other well known signs of failure.

The two rules mentioned in the query are most useful as far as rules go. Clinical interpretation and correlation of all the facts available is essential. Rules and specific test procedures are not infrequently fallacious and misleading. MacKenzie emphasized years ago that the best criteria of the patient's cardiac reserve and cardiac efficiency were the data derived from careful study of a detailed history. Rather than rely on some one or two test procedures or formulas it is wiser to evaluate the situation from as many sources of information as possible. Perhaps the most significant single observation is the ease with which dyspnea is induced by effort as compensation and reserve strength diminish dyspnea appears with less and less exertion. The degree of dyspnea per se is less important than the extent of effort required to induce it. This aspect of the situation is best illuminated by careful inquiry into the history the patient can thus report the effect of changes in weather (such as a cold wind), the effects of digestion, and other occurrences on his circulatory efficiency.

One must not ignore the fact that all evidences of circulatory embarrassment are considerably aggravated by coincident anemia. In fact most of the phenomena associated with reduction of the cardiac reserve can be brought about by profound anemia even relatively minor depression of the oxygen carrying capacity of the blood enhances the intensity of symptoms. In the present instance, examination of the blood and of the renal functional reserve and determination of the basal metabolic rate are indicated before final conclusions regarding the extent of purely cardiac damage are warranted.

USE OF WHOOPING COUGH VACCINE

To the Editor.—In the October issue of *Parents Magazine* page 80 Dr Emelyn Lincoln Coolidge in an article entitled *Safety via Vaccines and Serums* states that the Sauer vaccine for protection from whooping cough must not be used for at least four months after any other vaccine or serum has been given. Is this correct? Why? Please omit name.

M D New York

ANSWER.—Because whooping cough is more prevalent than diphtheria smallpox or scarlet fever and is serious only during the first few years of life it is advisable to immunize early. As the earliest age at which infants can develop immunity from the injection of the authorized vaccine has not yet been determined, it is best to give the injections during the second half year of life—preferably at about 7 or 8 months. Because a period of several months must elapse before the resulting immunity is complete other immunization or vaccinations should not be attempted within that time.

It is rarely if ever necessary to crowd the various immunization procedures. A recent three year summary of results with a total of 8 cc of the authorized vaccine for immunization shows that about 90 per cent of the children less than 3 years of age at the time of injection were protected when exposed to the disease from four months to three years after injection. Because failures occurred somewhat more often in children over 3 years of age at the time of injection, a total of 10 cc is now recommended for all children beyond that age. If another immunization has already been performed, sufficient time for immunity to develop from it should elapse before the pertussis vaccine is given.

A practical immunization schedule used by some physicians for several years, is to vaccinate first against whooping cough at 7 to 8 months then a single diphtheria toxoid alum precipitated injection against diphtheria at 11 to 12 months, when the Schick test reading is made from four to six months later and found negative the smallpox vaccination or scarlet fever immunization may be performed. By this plan all four immunizations can be completed relatively early in life without one conflicting with the other.

ROUTINE VISUAL TESTS IN SCHOOLS

To the Editor—During the routine examination of the eyes in school examinations what standard or test should be followed in rural schools? What percentage of defect should be present to demand correction immediately or soon? It doesn't seem practical to go through a complicated and detailed ophthalmologic examination in rural communities. Various eye charts for vision test are confusing some having distances and percentages on the same chart. What would you suggest as a brief reliable test for rural use? Omit name, please

M D, New York

ANSWER.—The only satisfactory routine measurement of visual acuity in school examinations is by means of the standard Snellen chart. For this, a testing distance of 20 feet is essential. Illumination must be adequate, at least 7 to 10 foot candles and preferably artificial illumination. Probably the most satisfactory chart is the Snellen chart, published by the American Medical Association containing notations of visual acuity and percentages of visual efficiency.

It is difficult to state empirically exactly what decrease in visual acuity necessitates further examination. That depends on the age of the child and the character and extent of the error of refraction that is present. When the error is small, visual acuity of 20/30 or even 20/40 may not necessitate correction. But if the error of refraction is great, particularly in a case of high hyperopia, even 20/25 requires further investigation. For routine purposes, one may say that visual acuity of 20/30 or worse in either eye should be the basis for refraction under mydriasis.

RELATIONSHIP BETWEEN LEUKEMIA AND CARCINOMA

To the Editor—Are the lymphocytes seen about carcinomatous infiltrations an irritative or an inadequate defense mechanism? Has blood taken from a patient or animal with lymphatic leukemia ever been transfused into a normal person or animal to determine what effect it might have? In other words could it possibly be transmissible in this manner? Likewise has blood from a patient with lymphatic leukemia ever been used in a patient suffering from carcinoma? It has seemed to me logical to assume on a theoretical basis that, if the lymphatic infiltration so frequently seen about carcinomatous tissue is an inadequate defense, an added number of lymphocytes a good source of which would be from a patient suffering from lymphatic leukemia might be of value. I understand that many of the cells (lymphocytes) when found in large numbers are immature and for this reason may not possess the antitoxic properties.

M D, Michigan

ANSWER.—It is assumed, at least by some that the accumulation of lymphocytes by carcinomatous infiltration may have defensive effects. In animals notably fowls and mice, various forms of leukemia are readily transmissible by injection of blood or cells. So far as known there is no recorded instance of the injection of blood from a patient with lymphatic leukemia into a patient suffering from carcinoma. Naturally, one would hesitate to make such an injection because of the possibility of thereby transferring leukemia.

UTERINE FIBROIDS NOT RELATED TO THICKENING OF SKULL

To the Editor—A married woman has a thickening of the inner table of the skull associated with uterine fibroids. So far her mentality is normal but she has some headaches and dysfunction of the right arm and both legs. May I ask for a frank discussion of the treatment you would advocate and the prognosis?

M D, Illinois

ANSWER.—The uterine fibroids are not responsible for the thickening of the skull, the headaches, or disturbed function of the right arm. Pressure, or venous engorgement associated with fibroids, might produce disturbances of the lower extremities, although it is uncommon in the absence of a complicating malignant condition or pelvic infection.

TONIC EFFECTS OF EMETINE

To the Editor—I have been using emetine in standard 6 cc ampules for the relief of stomach ulcer or duodenal ulcer. Recently one patient complained of weakness of the limbs resulting from this medication. As this is the first complaint I wondered what you might know about the toxic effect of emetine.

M D, New Mexico

ANSWER.—Muscular weakness is a prominent symptom of emetine poisoning. Such weakness may be due to direct action of the emetine on the muscles, to depression of the heart muscle, to collapse from excessive loss of fluid to neuritis, or to combinations of these. Excessively rapid intravenous injection may result in direct depression or paralyzes of the heart with no other symptoms than sudden weakness, fainting and even fatal collapse. In more slowly developing cases the vomiting and purging contribute to the collapse by inducing dehydration. It is a peculiarity of poisoning by emetine

that, even following a single dose, severe symptoms and even death may be delayed a long time. It may occur as long as a week later. When peripheral neuritis sets in it may prove fatal, especially in children and weak persons, in spite of interruption of the treatment at the onset of the neuritis.

BLEEDING AFTER INCISION OF VULVA IN PREGNANCY

To the Editor—I was recently called to see an 18 year old primipara within a few weeks of term. There was a tender and painful swelling of the left labium majus slightly fluctuating and rather edematous. I made an incision low down, about 1 cm broad and nearly 2 cm deep. There was a discharge of pus with a good deal of blood which had ceased by the time I left. An hour later she began to bleed in spurts and was taken to a hospital. The bleeding was checked and a day or so later another incision was made. The discharge has stopped by this time. What did I do that was wrong?

M D, California

ANSWER.—The painful swelling was probably a Bartholin gland abscess. The vulva is often highly vascular in the advanced months of pregnancy and a transverse incision might cause free bleeding. The usual practice is to incise longitudinally, not transversely, thereupon spreading the wound with forceps to insure good drainage.

GLOMUS TUMORS

To the Editor—In THE JOURNAL September 7, Dean Lewis reported a series of glomus tumors that had come under his observation. In view of the fact that I am unable to find a definition of the glomus in any medical dictionary I have will you please define the word and specifically locate it? Dr. Lewis mentions removal of these tumors. Will you kindly outline the technic, stressing necessary points of danger or trouble in their removal?

M D, Florida

ANSWER.—Glomus is derived from the Latin meaning ball and usually refers to a plexus of vessels. The word glomerulus used in the histology of the kidney is a diminutive of glomus and refers to a coil of blood vessels. Luschka in 1860 applied the term glomus coccyeum to a small organ situated near the tip of the coccyx. In applying the term glomus to the arterial angioneuromas, the resemblance of these tumors histologically to the glomus coccyeum of Luschka is emphasized.

Webster's dictionary gives the definition and use of glomus. These tumors can be removed under local anesthesia without any difficulty, and no danger or trouble should be experienced in their removal.

CONSTITUENTS OF THE NEURON

To the Editor—I should like to know the chemical constitution of the fluid contained within the cell body of the neuron.

R F. SUEETS, M D, Carthage, Ill.

ANSWER.—The "cell body" of the neuron consists of the semi fluid sticky gel called protoplasm. This is fundamentally the same in all cells. Since nerve cells have not been separated from other elements of nervous tissue for chemical study, it is not known specifically how their protoplasm differs from that of other cells. There are evidences that they are exceptionally rich in nucleoproteins. For a consideration of the great number of substances that have been separated from dead protoplasm, a textbook of physiologic chemistry must be consulted. The characteristic activities of any type of cell are the results of the cooperation of the various "organs" within the cell. These differ from one another both physically and chemically.

VEHICLE FOR PRESCRIBING BROMIDES

To the Editor—I have been trying in vain to prescribe bromides in U. S. P. and N. F. vehicles that would be as pleasant as the proprietary preparations put out by various pharmaceutical houses. I shall appreciate it if you will inform me of a vehicle that will compare favorably.

WILLIAM STEINBERG, M D, Philadelphia

ANSWER.—A comparative study of vehicles has shown that the syrup of glycyrrhiza is one of the best disguising vehicles for bromides. Its colloidal nature suppresses the salty taste to a considerable degree. The immediately perceived sweetness of the sucrose and the lingering sweetness of the glycyrrhizin add further disguising value. Flavoring the syrup with anise or an anise bouquet is advisable. This may be done by using anise water as the solvent for the bromide, since the syrup is too concentrated to dissolve a full dose of this salt. The following prescription may serve as an example.

| | |
|----------------------|--|
| R Sodium bromide | 30.0 Gm. |
| Anise water | 30.0 cc. |
| Syrup of Glycyrrhiza | to make 120.0 cc. |
| Mix and Label | Teaspoonful in glassful of milk after meals and at bedtime |

GLYCOSURIA

To the Editor—In Queries and Minor Notes in THE JOURNAL, October 12 page 1210 the following statement appears Glycosuria excreting 20 mg per hundred cubic centimeters of urine should cause rejection for employment or at least comprehensive study In Quantitative Clinical Chemistry by Peters and Van Slyke 1932, page 131 the excretion of dextrose in normal urine is said to occur in concentrations of from 0.02 to 0.10 per cent What method for dextrose determination was considered in presenting your figure?

E S WILLIAMS MD Richmond Va

ANSWER—The statement should read "Glycosuria exceeding 200 mg (or 0.2 per cent) per hundred cubic centimeters of urine should cause rejection for employment or at least, comprehensive study" The statement that 20 mg per hundred cubic centimeters of urine should so disqualify an applicant is incorrect, owing to clerical or stenographic error The method of dextrose determination employed is the trinitrophenol method of Benedict.

ISOTONIC SALT SOLUTIONS BY HYPODERMOCLYSIS

To the Editor—I am interested in learning about the effect of giving physiologic solution of sodium chloride and 5 per cent salt solution by hypodermoclysis I have been unable to find any literature pertaining to this Should 5 per cent sodium chloride ever be given subcutaneously? What factors other than injection too rapid flow and too warm solution might account for a slough of the soft tissues if physiologic solution of sodium chloride should be administered?

JOSEPH O HAWKINS MD San Rafael, Calif

ANSWER—Only isotonic solutions should be used for subcutaneous injection A solution containing 5 per cent of sodium chloride is too concentrated It produces inflammatory reaction and may even cause a slough In addition to excessive heat of solution, excessive distention of tissues and infection either carried in from without or brought to the tissues through the circulation, extremely poor circulatory activity in the part injected may favor production of a slough

BLOOD GROUPS IN TWINS

To the Editor—One of male twins was murdered The twin sister attempted to throw guilt on a third party by means of a cloth on which she put some of her own blood The age of the twins was about 40 Is there enough similarity in blood typing at that age to make it appear that the blood may have come from the murdered twin brother?

MD Pennsylvania

ANSWER—In monovular (or identical) twins the blood groups are invariably the same The twins described are of different sexes and are therefore biovular Biovular twins resemble each other neither more nor less than ordinary siblings Hence they may or may not have the same blood group though they are more likely to have identical groups than two unrelated individuals The age makes no difference since the blood group properties are demonstrable at birth and remain unchanged throughout life

TELEGONY

To the Editor—A dog breeder informs me that, if a thoroughbred bitch is raped by a mongrel the bitch is ruined as far as further breeding of thoroughbred pups is concerned Pups following this even though the bitch is covered by a thoroughbred will show characteristics of the mongrel If this is true, would the same apply to human beings? That is if a Negro raped a white woman who gave birth to a mulatto, and later she marries a white man would their children be liable to have Negro characteristics? Please explain

MD Idaho

ANSWER—There is no scientific evidence for and considerable evidence against telegony, which is defined as an influence of a previous sire on offspring of a later sire

ROENTGEN TREATMENT OF SINUSITIS

To the Editor—Has roentgen treatment of frontal sinus disease been successful? How many treatments are given and for what length exposure are they employed? Are there any contraindications to the treatment? At what stage is treatment most efficacious? What is the efficacy of autogenous vaccine treatment in frontal sinus disease? Please omit name

MD Ohio

ANSWER—Although some writers have reported favorably on roentgen treatment in sinusitis its use has not been generally accepted Details regarding roentgen treatment in chronic cases are given in the following articles

Butler F E. and Woolley I M. Roentgen Therapy in Chronic Sinusitis *Bent J Surg* 40: 379 (July) 1932
Butler F E. and Woolley I M. Roentgen Therapy in Chronic Sinusitis A Further Report *Radiology* 23: 328 (Nov) 1934

GONORRHEAL ARTHRITIS AND INFECTED PROSTATE

To the Editor—Kindly inform me as to whether or not the existence of gonorrheal arthritis implies necessarily an infected prostate.

M.D., California.

ANSWER—Gonorrheal arthritis occurs not infrequently as a complication of acute gonorrheal urethritis without any demonstrable prostatic involvement Occasionally gonorrheal arthritis may be diagnosed conclusively by demonstrating the organisms in fluid aspirated from the joint, although careful examination does not reveal any local genital, urethral or prostatic infection Gonorrheal arthritis is much more common secondary to gonorrhea in the male than in the female, but it may follow simple vulvovaginitis or ophthalmia neonatorum

EFFECT OF SYPHILIS ON HEALING OF FRACTURES

To the Editor—I would appreciate information concerning the role of syphilis in the healing of fractures Is it the modern belief that secondary or tertiary syphilis retards the healing or union of fractures? I have to appear in court next week so would appreciate an early reply Please omit name

MD, Pennsylvania

ANSWER—The modern belief is that syphilis does not retard the uniting of fractures Nonunion is seen most frequently in fractures of the neck of the femur, in the humerus and in the tibia The records of the larger clinics show few cases of coexisting syphilis

Council on Medical Education and Hospitals

ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in THE JOURNAL, July 6

Hospitals Approved for Intern Training

Wesson Memorial Hospital Springfield, Mass
St Joseph Mercy Hospital Pontiac, Mich
St Agnes Hospital White Plains, N Y
Evangelical Lutheran Hospital, Cleveland
Good Samaritan Hospital Dayton, Ohio
St Joseph's Hospital Lancaster Pa

Hospitals Reinstated to Approved Internship List

St Mary's Hospital San Francisco
St Elizabeth Hospital, Chicago
St Anthony's Hospital Rockford Ill
St Luke's Methodist Hospital Cedar Rapids, Iowa
Flushing Hospital and Dispensary Flushing N Y
St Mary's Hospital Cincinnati
Mount Carmel Hospital, Columbus Ohio
St Luke's Hospital, Milwaukee

Hospitals Approved for Residencies in Specialties

California Babies Hospital Los Angeles Pediatrics
San Diego County General Hospital San Diego Calif Medicine
ophthalmology-otology and surgery
Peoria Municipal Tuberculosis Sanitarium Peoria Ill Tuberculosis
James Lawrence Kernan Hospital Baltimore, Orthopedics
St Mary's Hospital Kansas City Mo Surgery
Mary Hitchcock Memorial Hospital Hanover N H Pathology
United States Marine Hospital Fort Stanton N M Tuberculosis
Beth Israel Hospital New York City Radiology
Longview State Hospital Cincinnati Psychiatry
St Vincent's Hospital Portland Ore Pathology
Abington Memorial Hospital Abington Pa Medicine pathology and surgery
Germantown Dispensary and Hospital Philadelphia Medicine and surgery
Skin and Cancer Hospital Philadelphia Dermatology

Hospitals Approved for Additional Residencies

Children's Hospital Los Angeles Pathology
San Francisco Hospital San Francisco Orthopedics thoracic surgery, tuberculosis and urology
Stanford University Hospitals, San Francisco Physical therapy
University of California Hospital San Francisco Neurosurgery and urology
Research and Educational Hospital Chicago Ophthalmology and radiology
University of Chicago Clinics Chicago Anesthesia neurology and psychiatry
Evanston Hospital Evanston Ill Surgery
Methodist Episcopal Hospital Indianapolis Radiology
St Mary's Group of Hospitals St Louis Ophthalmology and otology
Jewish Hospital Brooklyn Pathology
Millard Fillmore Hospital Buffalo Pathology
Metropolitan Hospital New York City Pathology
New York Post-Graduate Medical School and Hospital New York City Dermatology
Jewish Hospital Cincinnati Radiology
Memphis General Hospital Memphis Tenn Pediatrics

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Written examination for Group B applicants will be held in various cities throughout the country, March 14. Oral examination for Group A and B applicants will be held in Kansas City Mo. May 11-12. Applications for written examination should be filed with the secretary before Jan. 15. Sec. Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, March 28. Applications must be filed not later than February 28. Oral clinical and pathological examination of all candidates will be held in Kansas City Mo. May 11-12. Applications must be received not later than April 1. Sec. Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY Kansas City Mo. May 11 and New York Oct. All applications and case reports must be filed sixty days before date of examination. Asst. Sec. Dr. Thomas D. Allen, 122 S. Michigan Ave., Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis Jan. 11. Sec. Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY Kansas City, Mo. May 9. Sec. Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS Kansas City, Mo. May 9. Sec. Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York Dec. 30. Sec. Dr. Walter Freeman, 1726 Eye St. N. W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY Kansas City, Mo. May 8-10. Sec. Dr. B. R. Kirklin, Mayo Clinic, Rochester, Minn.

CALIFORNIA Reciprocity, San Francisco Jan. 15. Sec. Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO Denver Jan. 7. Sec. Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT Basic Science, New Haven Feb. 8. Prerequisite to license examination. Address: State Board of Healing Arts, 1895 Yale Station, New Haven.

DISTRICT OF COLUMBIA Washington Jan. 13-14. Sec. Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

HAWAII Honolulu Jan. 13-16. Sec. Dr. James A. Morgan, 48 Young Bldg., Honolulu.

ILLINOIS Chicago Jan. 28-30. Superintendent of Registration Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

MINNESOTA Basic Science, Minneapolis Jan. 7-8. Sec. Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. Medical, Minneapolis Jan. 21-23. Sec. Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

NATIONAL BOARD OF MEDICAL EXAMINERS Parts I and II, Feb. 12-14; May 6-8; June 22-24 and Sept. 14-16. Part III tentatively scheduled as follows: Chicago Jan. 7-9 and New York Jan. 13-15. Ex. Sec. Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

NEBRASKA Basic Science, Omaha Jan. 14-15. Dir. Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA Reciprocity, Carson City Feb. 3. Sec. Dr. Edward E. Hamer, Carson City.

NEW YORK Albany Buffalo New York and Syracuse Jan. 27-30. Chief Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH DAKOTA Grand Forks Jan. 7-10. Sec. Dr. G. M. Williams, 44 S. 3d St., Grand Forks.

OREGON Portland Jan. 7-9. Sec. Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

RHODE ISLAND Providence Jan. 23. Dir. Department of Public Health, Dr. Edward A. McLaughlin, 319 State Office Bldg., Providence.

SOUTH DAKOTA Pierre Jan. 21-22. Dir. Division of Medical Licensure, Dr. Park B. Jenkins, Pierre.

VERMONT Burlington Feb. 12. Sec. Board of Medical Registration, Dr. W. Scott Nay, Underhill.

WASHINGTON Basic Science, Seattle Jan. 9-10. Medical, Seattle Jan. 13-15. Dir. Department of Licensure, Mr. Harry C. Huse, Olympia.

WISCONSIN Madison Jan. 14-16. Sec. Dr. Robert E. Flynn, 410 Main St., La Crosse.

Oregon June Examination

Dr. Joseph F. Wood, secretary, Oregon State Board of Medical Examiners, reports the written examination held in Portland, June 18-20, 1935. The examination covered 11 subjects. An average of 75 per cent was required to pass. Thirty-eight candidates were examined, all of whom passed. The following schools were represented:

| School | PASSED | Year Grad. | Per Cent |
|--|--------|------------|----------|
| College of Medical Evangelists | | (1935) | 92 |
| Northwestern University Medical School | | (1935) | 87.2* |
| Creighton University School of Medicine | | (1934) | 88.5 |
| University of Nebraska College of Medicine | | (1933) | 86.9 |
| University of Oregon Medical School | | (1934) | 84.2 |
| 84.8 85.1 85.2 85.4 85.8 86.8 87.2 87.8 88.4 | | | |

Georgia October Examination

Mr. R. C. Coleman, joint-secretary, State Examining Board, reports the written examination held by the State Board of Medical Examiners in Atlanta, Oct. 8-9, 1935. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. One candidate was examined and passed. The following school was represented:

| School | PASSED | Year Grad. | Per Cent |

Book Notices

Doctors and Juries The Essentials of Medical Jurisprudence. By Humphreys Springston. Fabrikold. Price \$2. Pp. 150. Philadelphia: P. Blakiston's Son & Co. Inc. 1935.

The title of this volume is a misnomer. The book contains little information concerning juries and does not cover the essentials of medical jurisprudence. But its language is simple and its style easy; it is divided into numerous short chapters, it is printed in easily legible type, is bound in a flexible cover, is almost small enough to go into the coat pocket, and may well serve to aid a physician to pass away a few idle moments while waiting for something to turn up. Even so the reader, unless he is already versed in legal medicine, must be on his guard lest he be misled. A lawyer or a physician seriously in need of aid will hardly find it in this volume because the author has given no citations to support his statements.

The author's comments on the attire to be worn on the witness stand are novel, but they are practical and, corresponding as they do so closely with comment on the same subject by an English author (Kerr, D. A. J. *Forensic Medicine*, A New Text-Book for Students and a Guide for the Practitioner, New York, Macmillan Company, 1935, p. 29) seem to be of sufficient interest to justify setting them out at length (pp. 94-95).

Clothes may not make the man but they sometimes undo him. Most men—that is most jurors—resent duds and tailors' dummies but they also dislike ostentatious raggedness. Showiness of apparel whether of either extreme is likely to militate against its wearer. At the same time there is a universal approval of being well dressed as opposed to seeming either over-dressed or too slovenly. Ideal courtroom clothes are usually dark of conservative weave and cut and without ornamentation by way of accessories of haberdashery. Plain ties, plain shirts, inconspicuous appointments and appointments are least likely to arouse antagonism and the general rule is that all articles of dress should be such that they have to be looked at twice before being seen or noted. In some communities spats, wing collars, stick pins, wrist watches, gloves, canes, stiff hats and lodge or fraternal emblems create no distrust and are unnoticed in others they are as red flags to a bull, especially in regard to lodge buttons, emblems, rings and watch charms for with the many divisions of race, religion and affiliations existing in most towns it is unwise to display affiliation with any particular group and risk antagonizing an opposing group.

The author seems to be an earnest advocate of a policy advocated at times by physicians, under which a physician is not to testify against a fellow physician in support of a claim based on malpractice, even though the facts of the case are within

his own professional knowledge and he knows that the claim is just. The author contends (p 136) that

It is far better that a negligent and careless physician escape liability for damages than that a whole community or locality should suffer because strict justice in such case is enforced. Confidence of patients in physicians is invaluable and when this confidence is sapped by the publicity attendant upon malpractice suits and at the same time the physicians in that district are made timorous thereby the effect upon the public at large can be nothing but evil.

In support of his contention the author points out that indemnity companies have in some instances withdrawn from localities in which physicians have testified against fellow physicians and he alleges (pp 134-135) that, because of such withdrawal, the doctors tend to become overly cautious their nerve is sapped and their judgment warped by fear, and the result is that the general public fails to receive the medical care and attention in that sort of locality that it receives in other localities where such unfortunate conditions do not exist.

Unfortunately the author does not state the facts on which he bases this allegation or the lines of demarcation that he draws between a physician's being normally cautious and "overly" cautious, or between a physician's "nerve" being normal and his "nerve" being "sapped" and his judgment being sound or being "warped by fear." In the absence of such basic information a critic might suggest that the relative freedom from personal liability that a physician experiences when he carries malpractice indemnity insurance leads to carelessness, undue boldness and unsound judgment on his part and that the withdrawal of such insurance is not a detriment to either patient or physician but restores normal standards of care, courage and judgment.

A physician who has been regularly summoned as a witness in a malpractice suit cannot refuse to testify to facts within his own knowledge—unless by so doing he will incriminate himself—or to opinions based on those facts. But even if the rule were otherwise, physicians it is believed, should hardly engage in a conspiracy to deprive patients who are in fact injured by the malpractice of their physicians, of the medical testimony necessary to support their claims and to obtain justice. Such a policy hardly appeals to one's sense of fair play, and if enforced it would tend to deprive physicians of a proper sense of responsibility and drive juries to appraise damages on the basis of the evidence of irregular practitioners and of laymen.

The protection of the public, the author seems to believe, does not depend on the existence of financial liability on the part of the physician for the consequences of his own carelessness, ignorance, unskilfulness and bad judgment but on the revocation of the licenses of physicians found deficient in professional care, knowledge, skill or judgment. Dishonorable and incompetent physicians should be deprived of their licenses of course, but it is notoriously difficult to obtain evidence sufficient to accomplish that end, and but few patients would be likely to institute proceedings looking toward the revocation of their physicians' licenses, even though the law permitted them to do so, so long as such patients could obtain no personal advantage by such action. This book is hardly one to be commended as a guide to medical students, physicians or lawyers.

Hormone des Ovariums und des Hypophysenvorderlappens. Untersuchungen zur Biologie und Klinik der weiblichen Genitalfunktion. Von Dr. Bernhard Zondek, Professor an der Hebräischen Universität Jerusalem. Mit einem Anhang: Hormonale Schwangerschaftsreaktion. Hormone des Hypophysenhinterlappens. Second edition. Paper. Price 58 marks. Pp 638 with 177 illustrations. Vienna: Julius Springer 1935.

The second edition of this work which first appeared in 1931 and has already become a classic has been enlarged by the addition of fifteen chapters. It includes extensive discussions not only of experimental work but of technical methods and clinical applications, representing a synthesis of knowledge in one of the most fascinating fields of medical research in which the author has played a significant part. Important information not available elsewhere and much that would be accessible only by diligent search of the literature appears in this volume. The typography is excellent and the many illustrations, a number of which are in color are almost without exception well chosen, well executed and reproduced with unusual clarity. Extensive appendixes on pregnancy tests and on the chromatophorotropic hormone of the pars intermedia of the hypophysis are included.

Professor Zondek proposes in this edition a new nomenclature for the gonadotropic principles, taking into account differences in the effects of products from various sources not established at the time the original terms were suggested. Thus the gonadotropic principle of pregnancy urine remains "prolan," and the follicle stimulating and luteinizing factors, prolan A and B respectively, but the "synergistic" pituitary factor of Evans becomes "synprolan" and the gonadotropic complex of the pituitary (prolan plus synprolan) is designated "prosylin." This somewhat complicated terminology may be confusing to those not intimately acquainted with the work in this field, however until chemically pure fractions are available the nomenclature will inevitably remain in a state of flux.

One minor flaw in an otherwise excellent book is the lack of uniformity in the bibliographic references, necessitating in many cases more searching than should be necessary.

The author who is both a noted investigator and a practicing gynecologist is co-discoverer with Aschheim, of phenomena which they utilized as the almost infallible pregnancy test that bears their name. Their discoveries also led to the isolation from the urine of pregnant women of pure estrogenic compounds by Doisy, Butenandt, Marrian and others. The author and Aschheim share honors with Smith and Engle in this country for the discovery of the role of the hypophysis in the control of the genital system. These and numerous other important contributions provide an unusually sound and critical background for the material in this book, which will be an indispensable acquisition to the reference library both of investigators and of clinicians.

Dermatology and Syphilology for Nurses including Social Hygiene. By John H. Stokes M.D. Duhring Professor of Dermatology and Syphilology, the School of Medicine University of Pennsylvania. Second edition. Cloth. Price \$2.75. Pp 308 with illustrations. Philadelphia & London: W. B. Saunders Company 1935.

This is a thoroughgoing revision of the well known textbook for nurses. General consideration of skin diseases, including all the common ones and some of the less common, comprises the first ninety-seven pages. Seventy-one pages are devoted to treatment of skin diseases, with detailed instructions in nursing care. Thirteen pages are devoted to gonorrhea for the purpose of emphasizing the differences between gonorrhea and syphilis. The next ninety-two pages consider syphilis and its treatment, with minute details for the nurse who assists in the treatment. The last forty-two pages are devoted to social hygiene, social service follow up, and the normal ideals of sex life. A three-page appendix gives pertinent bibliographic references, and a glossary occupies thirteen pages, giving accurate easily understood definitions of the terms used throughout the book. A complete index is appended. One could scarcely hope in a small book for a more excellent exposition of dermatology and syphilology for nurses.

Lehrbuch der Gastroskopie. Von Dr. med. Norbert Henning, Privatdozent an der Universität Leipzig. Boards. Price 7.20 marks. Pp 88 with 45 illustrations. Leipzig: Johann Ambrosius Barth 1935.

According to Henning, a new textbook on gastroscopy became indispensable after the rapid spread of gastroscopy resulting from the invention of the flexible gastroscope. This instrument is now used in almost every large German hospital. The technical parts of former books on the subject had become obsolete. The work is based on several thousand gastroscopies, it is written only for gastroscopists. In spite of its brevity, one feels in each sentence the authority of an expert. Morawitz, director of the Medical University Clinic of Leipzig and now editor of the *Archiv für Verdauungs-Krankheiten* has written the preface in which he says: "A certain reserve toward gastroscopy seemed to be comprehensible as long as there were only rigid instruments, but since gastroscopy has become safe today this hesitation is not justifiable any longer."

If it is known that in my hospital several thousands of gastroscopies have been carried out during the past eight years, frequently with valuable diagnostic results, it will be understood why I will not do without gastroscopy any longer. It probably will become a procedure which the gastro-enterologist must master just as the urologist must know cystoscopy." After remarks on the anatomy and physiology of the stomach and after a discussion of the development of the flexible gastro-

scope, Henning describes the modern instruments. He begins with the old rigid instrument of Schindler because he believes that the experienced examiner will often prefer it and because it allows photography by the use of Henning's gastrophotographic camera. The wisdom of discussing rigid instruments is questionable, since they have become obsolete following the invention of the flexible gastroscope. "Blind" gastrophotography is considered of no value. The flexible gastroscope is described in detail. The contraindications and especially the indications are discussed. Henning believes that soon treatment of stomach diseases without exact morphologic diagnosis by roentgen examination and especially by gastroscopy will be stigmatized as a serious mistake if not malpractice. The preparation of the patient and the introduction of the instrument are well described. Henning's opinion that the orientation in the stomach is easy will not be shared by expert teachers in gastroscopy. It is certainly significant that the description of gastroscopic pictures of gastritis takes twelve pages but of ulcer and tumor pictures only three pages. The importance of gastroscopy in the diagnosis of chronic gastritis is emphasized and reference is made to the author's more extensive monograph on the subject. The importance of gastroscopy in cases of ulcer and carcinoma is also pointed out. The comparison of gastroscopic observations with those of the x-ray relief method is of the greatest value. It is regrettable that only a few colored pictures are included in this most commendable book. Henning thinks that the variety of observations is too great to be shown in colored pictures. The beginner will miss nevertheless the multitude of pictures as shown in the old obsolete book of Schindler and in the new work of Moutier. The seven pictures of the three different types of gastritis, however, are excellent. This book should be read carefully by every gastroscopist.

Elementary Zoology for Medical Students. By L. A. Borradaile Sc.D. Fellow and Tutor of Selwyn College Cambridge. Third edition. Cloth. Price \$3.50. Pp. 420 with 285 illustrations. New York & London: Oxford University Press, 1935.

This edition contains additional material on the protozoa and on embryology. The book as a whole contains an account of invertebrates and vertebrates adapted to the needs of the pre-medical or medical student interested in acquiring a basic background in zoology. Aside from embryology and evolution, the principles of biology are touched on only in the accounts of the animals selected as representative types. The illustrations are numerous and carefully selected to augment the text. The work as a whole is a compact and condensed account of a few type animals selected because of their medical or evolutionary significance.

Sex Behavior in Marriage. By Charles A. Clinton M.D. Cloth. Price \$2. Pp. 150 with 8 illustrations. New York: Pioneer Publications, Inc. 1935.

Here is another contribution to the innumerable books now available in this field. It is a brief, simple statement, not nearly so technical or even as well written as many of the other books now available. However, it will no doubt find a certain number of purchasers, as have all the other volumes now available in this field.

The Determination of Iodine in Biological Substances. By C. O. Harvey. Medical Research Council Special Report Series No. 201. Paper. Price 1s. Pp. 43 with 3 illustrations. London: His Majesty's Stationery Office, 1935.

The significance of biologic iodine is widely appreciated. Consequently numerous analytic methods have been developed for its quantitative detection. Since it is usually minute in amount, these have long given varying results in the hands of different investigators. A standard method, so that data may be carefully compared, is certainly desirable. In this monograph the British Medical Research Council, after extensive investigations, presents its choice of an adequate micro-method. This is based on Hurlley's modification of the von Fellenberg procedure. The principles of this fundamental procedure, which has also been extensively developed in certain American laboratories, consist of (1) basic ashing in nickel crucibles, (2) alcoholic extraction of the iodide, and (3) titrimetric or colorimetric determination of the iodine. The author has thoroughly subjected the details of these principles to critical

chemical analysis. As a result he presents a standardized von Fellenberg technic. This is still tedious and hardly yet adapted to the clinical laboratory. Nevertheless, it has yielded gratifying comparative results in the hands of competent analysts. It represents a more accurate research instrument for the investigation of iodine metabolism.

Medicolegal

Malpractice Liability of Physicians for Anesthetizing a Minor Without Consent of Parents.—The plaintiff, 20 years of age, injured his ankle. He was taken to the defendant, a physician, for treatment, neither parent accompanying him. Without obtaining the consent of either parent, but with the minor's consent, the defendant anesthetized him with ether and proceeded to "set the ankle" and apply a cast. The plaintiff and his father subsequently sued the defendant in the city court of New York, Bronx County, to recover damages for alleged malpractice and for an assault predicated on the theory that the defendant anesthetized the plaintiff without obtaining the consent of his parents.

Where there is an emergency which endangers the life or health of a patient, or where suffering may be alleviated, said the court, it is a physician's duty to do that which the occasion demands within the usual and customary practice among physicians in the same locality. To hold that a physician must wait until he has obtained the consent of a minor's parents, who may not be available, before administering an anesthetic or before giving to an injured minor the benefit of his skill and learning to alleviate pain and suffering, might result in the loss of many lives and in much pain and suffering that might otherwise be prevented. Under the circumstances in the present case, the court thought that it would be altogether too harsh a rule to hold the defendant liable because he did not obtain the consent of the father to the administration of the anesthetic. Since the defendant was confronted with an emergency, and since he obtained the consent of his patient, the consent of the father was not necessary. The court could find no evidence of malpractice and consequently dismissed the complaint.—*Sullivan v. Montgomery* (N. Y.), 279 N. Y. S. 575.

Malpractice Death During Administration of Ethylene and Ether Anesthesia.—The physician defendant administered an anesthetic, consisting of a mixture of ethylene, ether, carbon dioxide and oxygen, while another physician removed the patient's appendix and drained her gallbladder. The operating physician in order to facilitate the closing of the incision requested a deeper anesthesia. As the oxygen supply was becoming rapidly depleted, a full tank of oxygen had to be installed, which required about five minutes, during which time the physician-defendant continued to administer the anesthetic. At about the time he began to administer the fresh supply of oxygen, the patient ceased to breathe and died. The plaintiffs, the husband and daughter of the deceased patient, sued the physician defendant. From a judgment in favor of the plaintiffs the physician appealed to the district court of appeal, second district, division 1, California.

The plaintiffs contended that the patient's death was caused by suffocation due to the physician-defendant's negligence in failing to administer a sufficient supply of oxygen in the anesthetic mixture. The physician-defendant contended that death resulted from heart failure and surgical shock unrelated to the anesthesia. The medical experts agreed that the symptoms of an overdose of ethylene gas are cyanosis appearing before death, labored, rapid and shallow breathing, and a drop in blood pressure following cessation of respiration, but that a drop in blood pressure prior to cessation of respiration would indicate a death caused by heart failure. The evidence showed that the symptoms preceding the patient's death were cyanosis following cessation of respiration, normal breathing up until cessation of respiration, and a drop in the systolic blood pressure five minutes preceding death from 135 to 105. The plaintiffs' only expert witness, an osteopath, in answer to a hypothetical question which assumed a normal blood pressure

during the anesthesia and omitted the last blood pressure reading, and which did not assume normal respiration up until cessation of respiration, testified that in his opinion death resulted from asphyxiation. The district court of appeals held that the hypothetical question was palpably deficient in that it omitted to state the last blood pressure reading and contained false hypotheses in assuming normal blood pressure during the anesthesia and in assuming normal respiration up until its cessation. The opinions of expert witnesses, said the court, based on hypothetical questions, are admissible if they are honest opinions predicated on facts established by the evidence. They are inadmissible if based on essential facts which are not given in evidence on facts which are directly contrary to the evidence, or on statements omitting important facts. A hypothetical question need not include all the facts testified to and it may assume facts most favorable to the theory of the party propounding it. There may be an allowable variation between the facts assumed and the actual facts proved, but the material facts assumed must be substantially true. Where the material facts on which the opinion is based are untrue the opinion itself becomes false, misleading and incompetent. The court held that the opinion of the plaintiffs' expert witness as to the cause of death was worthless, because it was based on false hypotheses and its admission was reversible error because it prejudiced the physician-defendant's case.

Accordingly, the judgment of the trial court was reversed.—*Forbis v. Holzman (Calif.)*, 45 P (2d) 215

Corporate Practice of Dentistry Illegal in Illinois—The Dr Allison, Dentist, Inc., the plaintiff in this action, entered into a contract with the defendant dentist wherein the latter agreed, according to the record, "that he would not practice operative dentistry for a period of three years at any place within two miles of the corporate location. Shortly thereafter the dentist opened a dental office directly across the street from the corporate dental parlors and the corporation sought to enjoin the violation of the agreement. The trial court, in denying the injunction, held that the plaintiff corporation was illegally practicing dentistry, that the corporation's only damage would arise out of competition in a line of business which it could not lawfully follow, and that therefore the petition of the corporation for an injunction did not appeal to the conscience of a court of equity. The corporation appealed to the Supreme Court of Illinois, contending that section 18a of the dental practice act which prohibits corporations from practicing dentistry, was unconstitutional.

The Supreme Court, however, considered it to be unnecessary to pass on the constitutional question. The gist of the corporation's complaint, and its claim to equitable relief, was based on damages alleged to be feared through the defendant's competition in practicing dentistry. The practice of a profession said the court, is everywhere held to be subject to licensing and regulation under the police power and not subject to commercialization or exploitation. To practice a profession requires something more than the financial ability to hire competent persons to do the actual work. It can be done only by a duly qualified human being and something more than mere knowledge or skill is essential to qualify. The qualifications include personal characteristics, such as honesty, guided by an upright conscience and a sense of loyalty to clients or patients even to the extent of sacrificing pecuniary profit if necessary. These requirements are spoken of generically as that good moral character which is a prerequisite to the licensing of any professional man. No corporation can qualify. It can have neither honesty nor conscience and its loyalty must in the very nature of its being be yielded to its managing officers, its directors and its stockholders. Its employees must owe their first allegiance to their corporate employer and cannot give the patient anything better than a secondary or divided loyalty.

The corporation in its complaint, stated that the dentist had acquired secrets and confidential information in regard to the patrons of the corporation. It might be well inquired said the court in whom are these personal secrets imposed when a corporation attempts to practice? Can it be in the president alone or is he under the corporate duty of disclosing them to his directors? And are the directors under

the further corporate duty of disclosing them to stockholders? This very allegation of the corporation clearly demonstrates, the court said the inappropriateness of any corporate attempt to practice one of the learned professions involving personal and confidential relations, and most clearly demonstrates that such practice is not and cannot be open to commercial exploitation. The corporate charter of the corporation, the court said did not and could not authorize it to practice dentistry, and the trial court quite properly dismissed the complaint.—*Dr Allison Dentist Inc v Allison (Ill.)* 196 N E 790

Malpractice Sponge Left in Patient—The appellant, a physician, performed an appendectomy on the appellee, June 19, 1931. During the course of the operation the physician discovered that the patient had gallstones, and a second incision several inches above the first was made and the gallstones were removed. The second incision healed quickly and normally. The lower wound continued to discharge pus and did not heal. About six months later, the physician removed from the appendectomy wound a gauze sponge. Thereafter the wound healed in about two weeks. The patient sued the physician and obtained judgment for \$9,896, from which the physician appealed to the Supreme Court of Oklahoma.

The physician argued that if he adopted and used the recognized and customary method of keeping track of sponges, he could not be considered negligent even if a sponge was left in the patient's body. While there is substantial authority, said the court to the effect that the leaving of a sponge in the body of a patient constitutes negligence per se the better rule is that a physician, like other persons is bound to exercise ordinary care to avoid injuring any one with whom he comes in contact. The fact that a physician adopts and uses the recognized and customary method of keeping count of sponges will not afford a complete shield from liability, if in fact a sponge is left in the patient's body. The real test is whether the physician, and the nurses acting under his authority, exercise ordinary care in keeping track of the sponges and seeing to it that they are all removed before the incision is closed. The fact that in the present case one of the nurses who was assigned the task of keeping count of the sponges might have made a miscount would not alter the situation. The physician admitted that the nurses were employed and directed by him and he would therefore be liable for their acts of negligence in connection with the operation.

The physician further contended that an instruction given by the trial court imposed on the jury the duty to segregate the injuries suffered by the patient due to the negligence of the physician in leaving a sponge in her body from her injuries due to the operation itself, and that there was no evidence to support such segregation. It was admitted, said the Supreme Court, that the incision made for the removal of the gallstones, where no sponge was involved healed promptly and completely, and that the other wound drained pus and caused the patient pain and suffering continuously until the sponge was removed. Under these circumstances the court said it would be unreasonable to say that there was no evidence of extra suffering on account of the sponge.

After reviewing all the evidence, it was the opinion of the Supreme Court that the question of the physician's negligence was properly submitted to the jury. There was, however no evidence either lay or expert, to support the plaintiff's allegation that her injuries were permanent. Up to the time the appendectomy wound healed there was objective evidence of suffering a part of which at least, could be attributed to the presence of the sponge. After the wound healed, her sufferings were largely subjective and both the continuance of such sufferings and their connection with the sponge would be matters to be established by expert testimony. There was no such testimony offered and whatever suffering the patient may have endured after the wound healed could not be charged to the fact that a sponge had been left in the body, except as a pure surmise. In the opinion of the court, it clearly appeared from the size of the verdict that the jury must have taken into consideration probable future suffering. There being no competent evidence to support a finding of future suffering, the verdict was excessive. The court ordered, therefore, that if the patient consented to a reduction of the verdict to \$5,000

the judgment of the trial court, as thus modified, would be affirmed. Otherwise the judgment would be reversed and the cause remanded for a new trial.

The patient's husband filed a separate suit against the physician to recover damages for expenses and loss of services of his wife due to the alleged negligence of the physician. The trial court gave judgment for the husband in the amount of \$734, and this judgment was affirmed by the Supreme Court of Oklahoma—*Aderhold v Stewart (Okla.)*, 46 P (2d) 340, *Aderhold v Stewart (Okla.)*, 46 P (2d) 346.

Workmen's Compensation Acts Physician as an Employee or Independent Contractor—The Goodman Medical Association, composed largely of the employees of the Goodman Lumber Company, was organized for the primary purpose of furnishing medical and hospital services to its members. Dr. Jacob Gomber entered into a written contract with the association to perform such services as a physician and surgeon as were required to be furnished by the Goodman Lumber Company and another company under the workmen's compensation act of Wisconsin, to testify in any case arising out of industrial accidents to be superintendent of a hospital maintained by the association, and generally to render medical care to members of the Goodman Medical Association. On Aug. 2, 1932, he was requested by the Goodman Lumber Company and the association to testify before the industrial commission. On the way to the hearing, he injured two fingers of his right hand when his automobile door closed on them. Infection set in, necessitating first an amputation of the middle finger and later on the amputation of his arm. He sought compensation under the workmen's compensation act, and from a judgment of the circuit court confirming the order of the commission denying compensation, he appealed to the Supreme Court of Wisconsin. Pending the appeal, he died and his administrator was substituted as plaintiff.

It is obvious, said the Supreme Court, that the examiner, the commission and the circuit court regarded the contract between the association and Dr. Gomber as requiring the latter to render only professional services. It has been generally held that the relation between a hospital and a physician employed by it is not that of master and servant. Physicians and surgeons employed by hospitals to minister to the sick and the infirm continue to be professional men who practice their profession according to their best judgment and discretion. While so practicing they are in no sense of the word subject to the orders or control of their hospital employers or bound in treating the sick to follow their directions. In a note in 19 A. L. R. 1183 it is stated:

The decisions of which the rationale is that physicians and surgeons are not the servants of their employers are referable to the conception that they are professional men who are engaged on the understanding that they are to exercise their profession to the best of their abilities according to their own discretion but in exercising it they are in no way under his (their) orders or bound to obey his (their) directions. This theory as to the nature of their position necessarily implies that they are independent contractors—a designation which has sometimes been specifically applied to them.

In this case, however, Dr. Gomber was employed to perform many duties that were not professional in character. He served as superintendent of the hospital. While so acting, his status was that of a servant. *Schloendorff v Society of New York Hospital*, 211 N. Y. 125, 105 N. E. 92, 52 L. R. A. (N. S.) 505, Ann. Cas. 1915C, 581. He also managed the hospital pharmacy and in that capacity bought and sold drugs for the association. He was required to attend hearings of the industrial commission in which employees of either the Goodman Lumber Company or another company were interested. His attendance on such hearings was clearly under the control of the association. The association had the authority to direct him where and when to go. The workmen's compensation act of Wisconsin defines employee to include " (4) Every person in the service of another under any contract of hire, express or implied. " This language, in the opinion of the court, was sufficiently broad to bring the facts of the present case within it and to impel the conclusion that Dr. Gomber's status at the time he was injured was that of an employee.

The judgment of the circuit court was reversed, with directions to reverse the order of the industrial commission and to return the record to the commission for further proceedings.—*Gomber v Industrial Commission (Wis.)*, 261 N. W. 409.

Accident Insurance Sunstroke an Accidental Injury, Delayed Demand for Autopsy—The insurance company promised to pay certain benefits under a policy insuring "against the effects resulting directly and exclusively of all other causes, from bodily injuries sustained solely through external, violent and accidental means." The insured, during the usual course of his employment, suffered a sunstroke and died. The company, contending that the death was not accidental, denied liability. The beneficiary obtained judgment in the trial court, and the company appealed to the Supreme Court of Oklahoma.

The Supreme Court, in denying the company's contention that a sunstroke does not constitute an accidental injury, said it was not inclined to depart from the holding in the case of *Continental Cas. Co. v. Clark*, 70 Okla. 187, 173 P. 453, wherein it was said:

That accidental means is used to denote accidental cause and in case of sunstroke, if the same was suffered while the insured was engaged in his usual avocation or going about his affairs in an ordinary manner as any other person might have been under like or similar circumstances and did not intentionally and voluntarily subject himself to an intense heat calculated to produce sunstroke with the knowledge that it would probably occur then the sunstroke was suffered from accidental means or accidental cause within the meaning of the policy.

The insurance policy in the present case contained a provision entitling the insurer to an autopsy in case of death where such procedure was not forbidden by law. The insurance company contended that it was denied the right to make the autopsy. The insured died on July 27, and notice of the death was received by the company August 2. The body was buried in Mississippi July 30. Nothing was said by the company with respect to an autopsy until September 10, when demand was first made. Coupled with this demand was a further request for permission to remove any specimen or specimens for chemical, microscopic, pathologic, laboratory or other examination. The request was refused as not being in accord with the terms of the policy and for the further reason that the request was not made within a reasonable time. No claim was made that an autopsy would have disclosed that the insured died of or from any cause other than sunstroke. There was, therefore, no showing whatever that the company was prejudiced by the refusal of the request for an autopsy. In fact, the beneficiary never did refuse an autopsy within the terms of the policy, because no request limited to such terms was ever made. No explanation was offered for the delay of some five or six weeks in requesting an autopsy. The court held that there was no merit in this contention by the company.

Finding no substantial error in the record, the judgment of the trial court for the beneficiary was affirmed.—*Provident Life & Accident Ins. Co. v. Green (Okla.)* 46 P (2d) 372.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Lead 4 in Carditis in Rheumatic Fever.—Levy and Bruenn state that if successive electrocardiograms are taken in rheumatic fever, lead 4 may furnish evidence of active carditis when changes indicating active myocardial involvement are not observed in the standard three leads. Frequently gross variations in the contour of lead 4 indicate the significance of minor alterations in the three standard leads which might otherwise be regarded as of doubtful importance. This statement applies particularly to slight changes in the T wave in lead 3. On occasion, changes denoting rheumatic lesions in the cardiac muscle are present in the first three leads when no change is apparent in lead 4. In ambulatory patients with rheumatic heart disease, a single electrocardiogram may reveal evidence of myocardial damage only in lead 4. On the basis of a single record however it is not possible to establish the presence of rheumatic activity in the heart. Changes in the electrocardiogram characteristic of myocardial involvement were found in five patients whose hearts at necropsy showed lesions of active rheumatism. In two patients in whom active rheumatic carditis was suspected during life but was not found at necropsy, the electrocardiograms were normal. In rheumatic fever the use of lead 4 is of clinical value as an aid in the recognition of active myocardial involvement and in following its course.

Electrocardiographic Changes in Arterial Hypertension.—Rykert and Hepburn point out that in the course of an investigation into the serial electrocardiographic changes following acute coronary occlusion one of them found cases showing abnormalities of the ventricular complexes (QRST) of an unusual type. In certain respects the abnormalities observed in the records of these cases simulated and in other respects differed from the typical electrocardiographic changes found in myocardial infarction. Without exception these atypical records showed an identical type of electrocardiographic abnormality. A diagnosis of coronary thrombosis had been made largely on this electrocardiographic abnormality. The clinical histories while in some cases suggestive in practically all gave only inconclusive support to that diagnosis. Of 143 patients in the series, 124 had arterial hypertension at the time

the electrocardiographic records were obtained. The patient who had a systolic blood pressure of 160 mm of mercury or higher was considered to have arterial hypertension. Eighty-three had a systolic pressure of 200 mm of mercury or more, and in forty-one cases the systolic pressure varied between 160 and 200 mm of mercury. The diastolic pressure readings were correspondingly high. In the other nineteen cases the systolic pressure was found to be less than 160 mm of mercury. A diagnosis of myocardial disease was made in all cases. Of the 143 patients 126 had chronic degenerative heart disease. The size of the heart was determined accurately in eighty-three cases by means of orthodiagrams and in the remainder by percussion. Moderate to marked cardiac enlargement was present in seventy-three and enlargement of slight degree was present in the other ten. Objective evidence of cardiac insufficiency, i. e., rales at the base of the lung, enlargement of the liver and dependent edema was found in eighty-two cases and was more often of moderate than of marked degree. In the remainder congestive failure occurred with a normal heart rhythm. A diagnosis of endocardial disease was made in twenty-nine of the 143 cases. It was found in eleven of the nineteen cases in which the systolic blood pressure was less than 160 mm of mercury and in only eighteen of 124 cases in which hypertension was present. Aortic valve disease, either alone or combined with mitral lesions, occurred in twenty-seven of the twenty-nine patients who were found to have endocardial disease, and two had mitral stenosis.

Removal of Left Cerebral Hemisphere. Report of Case. R. Zollinger, Boston—p. 1055.

Lead Intoxication and Multiple Sclerosis.—Boshes analyzed specimens of cerebrospinal fluid from twenty-eight patients for lead by the Fairhall hexanitrite method. In one of sixteen cases of multiple sclerosis the fluid showed a positive result. The patient had been given sodium iodide, and the urine also showed lead. Of twelve other cases of various conditions in which one case of lead intoxication were abundant crystals found in the cerebrospinal fluid. In this case there was 0.2 mg. of lead per liter of urine. Taking all three studies into consideration there is no adequate proof for and ample evidence against the theory that lead is an etiologic agent in cases of multiple sclerosis.

Removal of Left Cerebral Hemisphere—Zollinger removed the left cerebral hemisphere because of extensive infiltration by a tumor in a right-handed woman. During the seventeen days that she survived, an elementary vocabulary was retained, which was partially increased by training in speech. It was difficult to evaluate the mental capacity of the patient. She was more calm after operation but was less willing to perform coordinated movements. She did experience emotional reactions, but they were not marked. The functions of the cranial nerves were well preserved except for slight weakness of the right side of the face and absence of the corneal reflex on the left. The spastic paralysis on the right side was replaced by flaccid paralysis. The presence of acute pain with motion of the joints or compression of the deep muscles demonstrated the existence of a center of sensation below the cortex. Studies of the vasomotor responses of the extremities by determinations of skin temperature did not show measurable alterations in peripheral temperature regulation on either the ipsilateral or the contralateral side.

Sympathetic Ophthalmia in New York State—Joy points out that sympathetic ophthalmia occurs less frequently than its diagnosis, since uveitis due to other causes, especially that due to tuberculosis, may give a similar clinical picture. A routine microscopic examination of the enucleated exciting eye is indicated if only for its statistical value. In 151 cases in which the clinical features of sympathetic ophthalmia were present, 126 exciting eyes were enucleated, forty-eight of which were examined microscopically in all but seven the diagnosis was confirmed. The forty-one cases in which the diagnosis was established showed a higher percentage of final visual defects than did the cases in which no microscopic examination was made. Pathologic examination would eliminate the question of correct diagnosis. Analysis of the forty-one confirmed cases indicates that: 1 The frequency of sympathetic ophthalmia is not decreasing. 2 Nonpenetrating trauma may not be a rare exciting cause. 3 Sympathetic ophthalmia due to cataract extraction is unusually violent and the prognosis grave. 4 The interval between injury to the exciting eye and the onset of sympathetic inflammation may vary from nine days to twenty-four years or possibly to forty-eight years. 5 Sympathetic ophthalmia may be feared for at least two months after enucleation of the exciting eye. 6 Removal of the exciting eye before the onset of sympathetic inflammation does not favorably influence the ultimate outcome if the enucleation is delayed twenty-six days or more after the injury. 7 Sympathetic ophthalmia in children is unusually severe and the outcome unfavorable. 8 Removal of the exciting eye favorably influences the ultimate outcome in the sympathizing eye.

Stream Pollution—Howe speaks of a triple threat in stream pollution: it is a direct menace to health by rendering water supplies dangerous and unfit to drink, it threatens many recreation spots on the shores of lakes and streams by making bathing dangerous, and streams may become periodically so offensive that property values in the vicinity are depreciated. Natural cleansing processes are effective to only a limited extent. Typhoid dysentery and infectious diarrhea are filth diseases transmitted through human excreta. Water contaminated by sewage carries the bacteria of these diseases. Edibles that have been irrigated with this contaminated water are a means by which these diseases may be transmitted. The importance of cleaning up streams cannot be overestimated. Dwellers near streams have the fundamental right to receive the water coming to them in its natural purity, and their obligation is to pass it on to their neighbors unimpaired in quality.

Pneumonectomy for Malignant Disease of Lung—Within the last eighteen months, Overholt operated on thirteen patients for carcinoma of the lung. Metastatic involvement was found on exploration in seven patients, and pneumonectomy was carried out in six patients with three recoveries. Two additional successful pneumonectomies have been performed on patients with suppurative disease of the lung, giving a total of five successful operations. In the patients with suggestive symptoms or a suspected primary malignant condition of the lung he employs chest roentgenograms, bronchoscopy, a search for metastasis including roentgenograms of the long bones, skull and spine, evaluation of the operative risk, preliminary pneumothorax and intrapleural thoracoscopy to determine, if possible, the presence or absence of pleural or mediastinal metastasis. It has been his policy (1) to explore all cases of proved carcinoma of the lung if an extension beyond the lung cannot be

demonstrated by the foregoing methods, provided the general condition is fair, and (2) to explore in the face of a negative bronchoscopic report if the history and roentgenograms suggest a peripheral neoplasm

Diagnostic Significance and Treatment of Hematemesis—Gardner groups the causes of hematemesis under the three headings of intrinsic gastroduodenal or jejunal lesions, varices and infrequent causes, and he states that 90 per cent of all cases of hematemesis are due to intragastric lesions. Moderate hemorrhage late in the course of chronic dyspepsia suggests gastric ulcer. Severe hemorrhage early in the course of chronic dyspepsia suggests duodenal ulcer. Slight hemorrhage in the course of chronic dyspepsia in a patient in the cancer age suggests carcinoma of the stomach. Profuse or fatal hemorrhage without any history of indigestion or illness suggests cirrhosis of the liver. Profuse hemorrhage with obvious splenic enlargement suggests splenic anemia. If the hemorrhage is not due to any of the conditions enumerated, less frequent and more obscure causes must be sought. The treatment of hematemesis, particularly that from peptic ulcers, is medical. Transfusions should be employed as indicated.

Pulmonary Tuberculosis and Valvular Heart Lesions—Buckingham and Hoffman state that recent observations have shown that the view of Rokitsansky that tuberculosis of the lung and heart disease do not occur together is untenable and that association of phthisis with primary heart disease is probably more common than is usually suspected. Lawason Brown in 7,115 necropsies on tuberculous patients found 0.9 per cent of valvular heart disease. Norris in 8,154 necropsies found 3.5 per cent. Anders reports six cases of mitral disease with pulmonary tuberculosis, and Bronfin and Simon on the clinical examination of 2,100 tuberculous patients found approximately 6 per cent with valvular lesions chiefly mitral insufficiency and stenosis, with varying degrees of cardiac symptoms. However the views of Rokitsansky are held by many competent observers. Five cases of pulmonary tuberculosis are presented three of rheumatic heart disease with mitral involvement and two with congenital heart disease which occurred in a series of 522 cases of adult pulmonary tuberculosis treated at the Kansas City Tuberculosis Hospital during the last two years.

Control of Typhoid—Galloway points out that typhoid vaccine given in adequate dosage to groups of people at an effective rate of 25,000 cc per hundred thousand persons annually or more will influence the typhoid case rate and, if given to more than 90 per cent of the population will control it. Sanitation alone will greatly reduce typhoid and in conjunction with other aids will control it. The carrier is the source of infection in an increasing proportion of the total cases as control measures become effective, case to case infection is relatively easy to prevent. Mass typhoid immunization should be abandoned and selective immunization used as soon as a stable low case rate is attained. Selective immunization is aimed to protect those known to be in especial danger from cases or carriers or from environmental factors. Complete epidemiologic study of cases is difficult while the case rate is high, but records of such a study may be prepared as soon as the case rate is reduced by vaccination or other factors. Final reliance for typhoid control in an area should rest on intensive case and carrier work and sanitation, meaning sanitation in its broadest aspects of ensuring good personal hygiene. Lauderdale County has apparently reached a low stable incidence of typhoid and is ready to reduce mass immunization in favor of selective immunization, sanitation and intensive case and carrier control. Mississippi is probably ready to reduce mass immunization gradually as a policy in counties with full time service, as a low stable typhoid case rate has been attained. However, this can be done only if intensive epidemiologic study and control of cases and carriers is instituted and maintained and a high degree of sanitation is reached.

*New Treatment for Chronic Ulcers of Leg and Foot C H Verovitz Cleveland—p 850

Treatment for Chronic Ulcers of Leg—It occurred to Verovitz that breaking up of the fibrotic ring or sclerosed tissue surrounding ulcers (lifting the ulcer from its bed) and injecting a fresh supply of nourishing material, as blood, are needed for the healing of these ulcers. This he accomplishes by injecting patient's whole blood in the margin near the ulcer. In giving the injections, the ulcer and the edges surrounding the area are

cleansed with alcohol. A 2 per cent solution of iodine is painted over the area where the injection is given. A 10 cc Luer syringe, with a 23 or 24 gage needle from 1 to 1½ inches in length, is employed. About 10 cc of blood is taken from any of the veins at the bend of the elbow and is immediately injected in the ulcer. The injection is started one-fourth inch from the edge of the ulcer. The needle is inserted until it passes the resistant fibrotic area. The blood is slowly injected while the needle is gradually withdrawn. Sometimes one injection is given at a sitting, or multiple injections up to four have been given from one-fourth to one-half inch apart, depending on the size of the ulcer. In the first treatment the injections are started near the edges, and in the next treatment one-fourth inch nearer the center of the ulcer and so on. In some cases the entire circumference was injected. In the beginning this procedure is frequently painful, and it is advisable to anesthetize the ulcer with a 2 per cent solution of procaine hydrochloride near the edges. Considerable force will be found necessary in order to penetrate through the sclerosed area. In the beginning of the treatment little bleeding is noticed from the needle puncture, but when new blood vessels and granulations begin to form bleeding becomes free. The treatment is repeated once a week until the ulcers show signs of healing, and then the injections are discontinued. The number of injections varies with the size and chronicity of the ulcer and with the extent of fibrosis in the surrounding area. Every two days the ulcer is cleansed with alcohol and dried and 2 per cent mercuriochrome is applied the latter having some astringent properties. The ointment giving the best results is enough 10 per cent gentian violet applied on gauze to cover the ulcer. The clinical course of the healing of the ulcer appears as follows. The edges soften, bleeding from the needle puncture is free, and pink and healthy granulations appear at the base and edges. A seam of epithelium grows from the periphery toward the center of the ulcerated area. Sections taken from the healing ulcer show the base clean and free from necrotic material the infiltration diminished and rete pegs spreading over the edge. Normal vessels with a single row of endothelial lining appear instead of the thrombosed infiltrated capillaries.

Treatment of Hemorrhage by Injection of Blood Substitutes.—Hoitink compared several artificial blood substitutes to determine their action in acute dangerous hemorrhages. For that purpose fatal hemorrhages that were biologically equivalent were produced in dogs to discover whether the dog's life could be saved by the injection of blood substitutes into the blood stream. In addition a study was made of the influence of the infusion fluids on the blood, and of the hemorrhage and sub-

sequent infusion of substitutes on the urine and sodium chloride excretion. It was found that none of the infusion liquids gave better results than the sodium chloride solution. The injection into a vein of a 0.9 per cent solution of sodium chloride after an acute dangerous hemorrhage is preferable to the use of other artificial substitutes and to blood transfusion.

The Hypertonic Wet Dressing.—Taylor shows that the amount of fluid that can be withdrawn by a hypertonic solution from 1 square inch of wound surface is from 12 to 15 cc an hour. This amount varies between these figures regardless of the hypertonicity or nature of the solution. In general the more concentrated solutions gave the higher figure, but to all practical purposes they were identical. This at least held true for solutions with a hypertonicity between 3 and 23 (2.5 and 20 per cent sodium chloride). The values given are maximal for the animals used. They represent figures for new wounds with vascular muscle bases. In older wounds that had started to granulate, with surfaces partly covered by fibrin, the values varied to a considerable extent in different animals and were found to be lower. The fluid withdrawn by a hypertonic solution is water and not serum similar to that seen in burns. It contains only the amount of protein material that would normally diffuse from the wound. There is no increment of this caused by the hypertonic solutions. The value of this withdrawal seems to the author to be debatable for after the initial dehydration of the surface tissues, the continued outpouring comes from the blood vessels themselves and is dependent on the vascularity of the area. In the light of the author's experiments on wet dressings, an effective hypertonic solution reaches only the superficial tissue. That the deeper tissues containing the active infection cannot possibly be reached by the solution is evident. The chief benefit derived from this type of dressing is its poulticing action. This keeps the skin soft and pliable. It prevents crusting and allows drainage. Above all, it soon becomes warmed by the body and this markedly increases the flow of capillary blood, thus improving the defense mechanism against infection. Bearing out this contention is the fact that isotonic saline and even hypotonic solutions (1:5,000 mercury bichloride) have been seen to give the same beneficial effects noted in hypertonic solutions.

Kraurosis Vulvae and Circumscribed Scleroderma.—Ketron and Ellis state that kraurosis vulvae (leukoplakia of the vulva) shows in a considerable percentage of cases peculiar degenerative changes in the connective tissue identical in appearance with those characteristic of white spot scleroderma. They believe that some cases at least which are diagnosed leukoplakia are examples of white spot scleroderma of the vulva. Here the characteristic degenerated collagenous bundles may be entirely replaced by secondary inflammatory and sclerotic tissue owing to various local irritants. It is possible also that the vulvar tissue is peculiarly susceptible to degenerative processes in the connective tissue and that, in some cases, these changes may be only incidental to various inflammatory processes in this location. Leukoplakia of the vulva (clinically whitish patches) may be produced either by degenerative processes in the connective tissue, maceration of a hyperkeratotic epidermis, or a combination of the two. Leukoplakia of the vulva (histologically acanthosis and hyperkeratosis) probably is frequently superimposed on various pathologic processes of the vulva whether primarily of a degenerative or an inflammatory nature.

Treatment of Vaginitis with Estrogenic Substance.—Davis observed that the use of an estrogenic substance, amniotin (Squibb), in the treatment of senile vaginitis rapidly restores the normal adult epithelium seen during active sex life. The simple restoration of the epithelium leads to a healing of the ulcerated areas, a disappearance of the inflammatory symptoms, a cessation of the adhesive manifestation and a complete disappearance of all symptoms. No undesirable effects have been noted, nor can they occur during the postmenopausal period. Although the vaginal mucosa reverts to the normal senile type, the symptoms do not recur. Interesting biopsy specimens showing all the changes initiated by the estrogenic substance in the vaginal mucosa are presented. The treatment is simple, inexpensive and entirely feasible. The biopsy method of study can be used as an aid in all endocrine studies in the human female.

*Pneumonia and Other Common Respiratory Conditions in the New Born Clinical Study W. S. Craig—p. 599

Pneumonia in Infants—Craig correlates the clinical and pathologic results of 146 necropsies on new-born infants presenting some of the common respiratory conditions. In many infants the lungs are healthy and well expanded, simple atelectasis is a frequent observation, bronchitis occasionally occurs alone, and consolidation is common and may result from pneumonia or/and hemorrhage. Inflammation and hemorrhage are frequently found in atelectatic tissue. Respiratory conditions are particularly prone to occur in premature infants and children born severely asphyxiated, they are frequently associated with cerebral hemorrhage. A "ratchet" or "cogwheel" element in the breathing is sometimes heard over atelectatic tissue and when present is diagnostic of the condition. Bronchitis is much less common than pneumonia, the physical signs may be extremely localized, but they do not differ from those present at other age periods. Recovery occurs in mild cases, which usually have a febrile course. Pulmonary consolidation can be diagnosed during life in a large number of cases but it is not possible to determine whether it is the result of pneumonia or intrapulmonary hemorrhage. Crepitations of a peculiarly fine crackling nature can be heard over the affected tissues in the majority of cases of pneumonia or intrapulmonary hemorrhage; they are diagnostic of consolidation and are not found in other respiratory conditions of the new-born. Periodic attacks of cyanosis are constant in cases of pulmonary consolidation; administration of oxygen results in an appreciable improvement in color. Attacks of cyanosis occurring in other neonatal conditions (intracranial hemorrhage, urinary infection, septicemia, atelectasis) are not influenced to the same extent by oxygen administration. The prognosis in cases of pulmonary consolidation is grave, the majority die within a few days of diagnosis. Three cases are described in which clinical examination led to a diagnosis of pneumonia and eventual recovery. They differed from fatal cases in that they all showed continued high fever.

Patients Discharged from Mental Hospital Against Advice—Minski states that of ninety patients who left the Maudsley Hospital and went home against advice seventeen cannot be traced, twenty-five are in mental hospitals, twenty-four have recovered, sixteen are at home no better, seven committed suicide and one died at home. Obviously the standards of behavior determine the relatives in taking patients home and for this reason the largest number taken home while still ill were suffering from depressive states in which behavior likely to lead to conflict with the environment is not marked. It seems necessary to urge relatives of patients suffering from severe depressive states to send them to suitable hospitals. Most of the patients suffering from depressive states who remain at home, although ill, are of the involutional type, and only two who might reasonably be expected to recover remain ill in difficult home situations. The relatives seem to take a more serious view of states with excitement, only four manic patients and three with toxic confusional states were taken home while excited, no unrecovered schizophrenic patients remain at home.

Agranulocytosis with Meningitic Symptoms—Goadby and Worster-Drought discuss the occurrence of meningitic symptoms in a case of agranulocytosis in which the cerebrospinal fluid was examined. Opportunity was afforded also for chemical and histologic examination of the blood during the prodromal period of a relapse. The diagnosis of agranulocytosis was made during an illness that started in April 1934 with vomiting, pyrexia and ulceration of the gums. After a few weeks the more acute symptoms yielded to injections of penicillin but there were subsequent relapses in May, June, September and December 1934 and a severe one toward the end of February 1935. It was during this last attack that definite meningitic symptoms—drowsiness, rigidity of the neck and Kernig's sign—were first observed. Each of the previous relapses had been ushered in with pyrexia, languor and prostration, but no physical signs indicating involvement of the nervous system were detected. During each relapse the granulocytes fell to a very low level, the spleen was palpable and abnormal signs—dulness and crepitations—appeared at the base of the left lung. At no time during the entire course was Bacillus fusiformis or Vincent's spirochete detected in films from the ulcers of gums, throat or tongue.

- *Weltmann's Serum Coagulation in Clinic. G. Carrière, P. Martin and A. Dufosse—p. 1649
 Study of Pigmentation in Alopecia Areata. F. Woringer and R. Thee.—p. 1652
 *Scleroderma with Sclerodactylia Treated by Cervical Sympathectomy. D. Pléteff and T. Plotkin—p. 1653

Weltmann's Serum Coagulation—For eight months Carrière and his co-workers studied the serum coagulation reaction of Weltmann in various diseases. The principle of the method is to place constant quantities of blood serum in the presence of increasingly strong solutions of calcium (or barium) chloride, running from 0.1 to 1 per thousand. The reaction is read after the tubes have been removed from the warm water bath. They may be clear or show a simple opalescence or a flocculation. The result, which measures the heat coagulation of serum in the presence of calcium ions of growing concentration, allows the determination of the so-called band of coagulation. This band may be increased or diminished. Its increase is in general associated with a fibrous process and its decrease with an inflammatory one. According to the authors' experience, the band is increased in tuberculosis when the process is fibrotic and is diminished when it is exudative or pneumonic. In chronic rheumatism the reaction is helpful in diagnosis and prognosis for the same reasons. In hepatic disorders, especially cirrhosis, the increase in the band appears constant. The band appears decreased in the majority of cancer cases. Finally in exudates and transudates the band is decreased as in inflammatory conditions. The authors feel that this reaction offers additional help to that provided by other laboratory tests.

Scleroderma Treated by Sympathectomy—Pléteff and Plotkin report a case of scleroderma with sclerodactylia which responded well to cervical sympathectomy. They believe that the sympathectomy acts on the function of the parathyroids and diminishes calcemia. Periarterial sympathectomy of the arteries of the arm in cases of scleroderma associated with involvement of the upper extremities and sclerodactylia gives no result and it is necessary to attack the stellate ganglion directly.

- *Cancer of Colon. Atypical Onset. M. Chiray and Georges Rosanoff—p. 1689
 Facilities and Difficulties of Diagnosis of Duodenal Ulcer. R. A. Gutmann and G. Voulpiotis—p. 1691

Cancer of Colon. Atypical Onset—Chiray and Georges-Rosanoff discuss the various types of atypical onset of cancer of the colon. It is sometimes manifested by a prolonged febrile state without any localizing symptoms. This form is not well known. Sometimes it sets in with intestinal symptoms without the characteristics of cancer. This may resemble appendicitis, intestinal tuberculosis, simple colitis, or diverticulitis. Sometimes the onset may take on the aspects of an extra-intestinal disorder, such as gallbladder disease, hepatitis, simple dyspepsia, urinary manifestations and, in women, genital conditions. The practical conclusion that can be drawn from this discussion is that one should not hesitate to make repeated roentgen examinations, since colonic cancer cannot be eliminated on the strength of one negative examination.

Treatment of Intolerance to Milk—In discussing the pathogenesis of sensitivity to milk, Beverini states that digestive disturbances occurring in infants are a manifestation of anaphylaxis. He advocates subcutaneous injections of milk. The milk injections are specific breast milk vaccines against breast milk only and cow's milk against cow's milk only. The symptomatology of the condition consists in vomiting after

feedings, obstinate constipation, fatty stools, eczema and impetigo. When cow's milk is injected the temperature rises for several hours, sometimes for as many as ten hours. This does not occur when breast milk is administered. An injection of breast milk produces a slight erythematous reaction that disappears in the course of one or two days, whereas that of cow's milk produces a marked erythematous reaction. The author reports on two infants, aged 16 and 8 days, respectively. The children were treated with progressive doses of breast milk heated to 110° C. for twenty minutes. Preliminary doses of 1 cc. and 2 cc. of milk were injected subcutaneously one hour apart and were followed by a dose of 5 cc. injected subcutaneously into the flank. After the third injection, from 5 to 10 cc. of milk was injected every other day. The treatment was well tolerated. After four months of milk injections, the first child showed great improvement, but an acute intercurrent gastro-enteritis set in suddenly with a fatal result. The other child presented deficient assimilation of food and abnormal amounts of fat in the feces. Dyspepsia aggravated the intolerance to milk. Under treatment the general condition improved. The child became more lively, had more color and gained weight. The feces lost their dyspeptic character, indicating that the assimilation of fats had improved.

 Autohemotherapy in Arterial Hypertension. G. Pizzillo—p. 1505
 Takata Test in Diseases of Extrahepatic Biliary Tract. G. Manzoni—p. 1508

New Sign for Diagnosis of Pleural Effusion—D'Amato states that, in patients with pleural effusion, there is an area of dullness on the segment of the vertebral column near the posterior costomediastinal sinus of the pleura. The sign that he describes for the diagnosis of pleural effusion consists in the displacement of the dullness from the vertebral segment to the cardiac area, when the patient changes from the sitting position to the lateral decubitus and lies on the side opposite that in which the pleural effusion is located. The displacement of the vertebral dullness is due to the passage of the pleural fluid from the posterior to the anterior costomediastinal sinus of the pleura during the change of position of the patient. The dullness of the cardiac area increases on both sides. Its increase on the side on which the patient lies is due to the gravitational displacement of the heart and on the opposite side to the new location of the pleural fluid in the anterior costomediastinal sinus of the pleura.

A Test for Liver Function—Zinny reports a test for functions of the liver and of the biliary tracts. The results of which indicate whether an operation, especially cholecystectomy, should be performed on patients suffering from diseases of the liver or the biliary tract. It determines the amount of azorubin in the duodenal secretion, which is collected by means of duodenal tubage during the first hour of elimination of the dye that follows the intravenous injection of 4 cc. of a 1 per cent solution of azorubin. The determination is made by identifying the color of the duodenal secretion in a tube with that of a mixture of a 1 per cent solution of azorubin and ammonium picrate (of the color of the C bile) in the control tubes that form the colorimetric scale, previously prepared with twenty tubes, numbered from 1 to 20, each containing increasing quantities of from 0.05 to 1 cc. of the 1 per cent solution of azorubin and decreasing quantities of from 4.95 to 4 cc. of the solution of ammonium picrate. The colorimetric scale corresponds to concentrations of from 0.001 to 0.02 Gm. of azorubin in the duodenal secretion. If the liver and the biliary tract are normal,

the dye appears in the duodenal secretion within fifteen and thirty minutes after the injection. Its elimination lasts about three hours. The normal hourly elimination ranges between 0.01 and 0.018 Gm of the dye, 0.01 Gm being considered the lower normal limit. An elimination of 0.008 Gm indicates incipient impairment of the liver but does not contraindicate operation, 0.006 Gm makes operation inadvisable for the time being but may improve with treatment, and the operation can be performed when the results of the test, repeated at intervals of five or eight days are better. An elimination of 0.005 Gm indicates grave liver or biliary insufficiency that prevents operation, except in cases of emergency. Even in such cases it is dangerous in spite of the intensified preoperative and postoperative care of the patient. An elimination lower than 0.003 Gm an hour indicates too serious an involvement of the liver and biliary tract to operate. The author states that the test is harmless, has no contraindications, is of a simple technic and may be repeated whenever necessary.

Pathologic Physiology and Clinical Aspects of Atrioventricular Dissociation I. Oettinger —p. 117

Hemolytic Hypersplenism—Heilmeyer separates from the group of disorders collectively designated as acquired hemolytic icterus a definitely defined disease entity, namely, hemolytic hypersplenism. The symptoms of this disorder are severe hemolytic anemia with considerable increase in the blood exchange (reticulocytosis of from 100 to 400 per thousand and urobilin elimination in feces of from 700 to 3,000 mg.) absence of hepatic changes, absence of bilirubinuria, reduction of osmotic resistance, microspherocytosis, splenic tumor, sudden onset of the disorder and lack of symptoms of congenital hemolytic icterus in the anamnesis, absence of constitutional hemolytic signs, absence of similar disturbances among the relatives, and cure of the hemolytic anemia with complete disappearance of the reduction in the resistance and of the microspherocytosis following splenectomy. From the complete reversion of the biologic and morphologic changes in the erythrocytes after splenectomy the author concludes that this acquired disorder is not a disease of the bone marrow or of the erythrocytes but rather of the spleen. This is borne out also by a comparison of the measurements of the erythrocytes in the splenic artery and in the splenic vein. It reveals that in passing through the spleen the erythrocytes become thicker and simultaneously their spherical diameter becomes reduced (microspherocytosis). Although there are as yet only isolated cases with this aspect, they nevertheless throw some light on the process of splenic hemolysis in this disorder. The author suggests an investigation of this problem in cases of congenital hemolytic icterus. In discussing the etiology of hemolytic hypersplenism, he calls attention to the significance of severe infections. It is possible that severe disturbances in the endocrine correlations may likewise play a part in the etiology, for the author cites a case of hemolytic anemia with splenic tumor which developed after a severe thyroid and hypophyseal disturbance.

Histamine in Treatment of Allergic Conditions (Bronchial Asthma, Urticaria) A. D. Smith —p. 1612

Action of Estrogenic Substance Applied in Vagina—Berger says that in studies on the resorption capacity of the skin of rats for estrogenic substance it was decided to determine the efficacy of estrogenic substance in case of direct application

to the vaginal mucous membrane. It was found that this instillation required much smaller quantities for elicitation of estrus than did subcutaneous administration. The experiments were made on adult, castrated rats. The author states that 0.05 cc. of fluid can readily be instilled into the vagina of the rat by means of a thin urethral catheter and an especially calibrated record syringe. An ampule containing 100 mouse units of estrogenic substance was diluted in the required manner and 0.05 cc of fluid was instilled five times in the course of thirty-six hours. By dilution of the extract and by repeated injections it was possible to avoid the sources of error that are involved in the use of extremely small doses. It was found that in vaginal application, 0.5 mouse unit was sufficient to elicit estrus in rats, whereas in the case of subcutaneous administration more than 6 mouse units was required. In the estrus that was produced by instillation, noncornified epithelia were often found among the cast-off, non-nucleated horny lamellae. In this respect this type of estrus differs from that produced by the subcutaneous administration of estrogenic substance.

Histamine in Treatment of Allergic Conditions—Dzsinich calls attention to the great similarity between histamine shock and anaphylactic shock and points out that on the basis of this observation it was assumed that histamine plays a part in allergic conditions. The investigations that were made in connection with this hypothesis corroborated the assumption of the important role of histamine in the allergic reaction, namely, of the histamine that is liberated by the cells in the sensitized organism. It is assumed that in asthma histamine is liberated by the vascular cells of the bronchi, in urticaria by those of the skin, in hay fever by those of the nasal mucous membrane and in migraine and epilepsy by the vascular cells of the brain. The histamine and histamine-like substances thus liberated supposedly elicit endogenously the local and general symptoms of these disorders. If this stand is taken it seems justified to assume that allergic persons can be desensitized against this endogenously produced histamine by the exogenous introduction of small doses of histamine. The author decided to try this therapy in fifteen cases of bronchial asthma and in three cases of urticaria. In severe cases he began with 0.00001 mg. of histamine, in the milder ones with 0.0001 mg. The first injection was given intracutaneously and when it caused no noticeable reaction the same dose was given subcutaneously on the following day. Later, the injections were given at intervals of two days. In a few cases the daily treatment was tried but was found inadvisable. The doses were gradually increased but the author advises against their being increased beyond 0.01 mg. A table shows that this maximum dose is reached in severe cases after the twelfth and in milder cases after the ninth injection. Quite frequently, ten or twelve injections resulted in complete disappearance of the symptoms, but in other cases up to thirty injections were required. Summarizing his results the author says that with a suitable technic and an individualized dosage histamine treatment may produce permanent and satisfactory results in bronchial asthma as well as in urticaria. Although he had some failures in his rather small material, he nevertheless considers the method worthy of further trial.

Anaphylactic Spring Edema of Lung D. Engel —p. 1466

Pathologic Anatomic Aspects of Artificial Respiration in Death from Drowning D. Schenke —p. 1466

Differentiation of Diaphragmatic Hernia from Diaphragmatic Relaxation—Bohme points out that on the basis of a roentgenoscopy it is frequently difficult to determine whether the arched shadow in the right thoracic space represents the liver that has passed through a diaphragmatic cleft, or whether the liver together with the diaphragm has become elevated because of a relaxed diaphragm. In the left side of the thorax the same doubt may apply with regard to the stomach. More-

over, the paradox motility that is usually cited in support of the diagnosis of diaphragmatic paralysis is observable also in case of traumatic diaphragmatic hernia, when large portions of the abdominal viscera have ascended into the thorax. After pointing out that the isolated electrical irritation of the phrenic nerve as well as kymographic tests are of no value in the differentiation, the author stresses the importance of this differentiation, stating that, although relaxation of the diaphragm resulting from phrenic paralysis is frequently irreparable, diaphragmatic tears are amenable to surgical repair. It is therefore desirable to know of a reliable symptom that permits definite differentiation. The author calls attention to an esophageal-diaphragmatic phenomenon suitable for this purpose. He shows that the *contraction phenomenon* elicited by the contracting diaphragm on the esophagus at the esophageal hiatus is helpful in testing the function of the diaphragm and in determining the localization of the diaphragm in otherwise obscure topographic conditions. This constriction appears also when the abdominal muscular pressure is exerted. It frequently is lacking or considerably reduced in case of paralysis of one side of the diaphragm. If there is a suspicion of a tear in the diaphragm and of displacement of abdominal organs into the thorax, and if in this case a constriction of the esophagus at the hiatus develops in response to a unilateral electrical irritation of the phrenic nerve, it denotes diaphragmatic hernia and contradicts diaphragmatic relaxation.

*Cure of Syphilis with Spirochetal Vaccine Hilgermann—p. 1760

Experiences in Treatment of Suppurating Anginas with Bismuth Preparation Stüch—p. 1761

Cure of Syphilis with Spirochetal Vaccine—Hilgermann states that he has demonstrated that the efficacy of chemotherapy is not the result of its sterilizing effect but rather of an immunizing action. To be sure, the chemotherapeutic effect is based on the parasitotropic action of chemical substances, not in the sense of a sterilization but rather in the sense of a killing of some of the pathogenic organisms, the liberated toxins of which present an adequate specific stimulus for the elicitation of an active immunization. The chemical substance neutralizes the endotoxins of the pathogenic organism, and the neutralized toxins stimulate the formation of defense substances. The chemotherapeutic agent arsphenamine fulfils its parasitotropic action completely if a sufficient amount of protective substances are present in the organism. This was proved by several investigators in cases in which chemical substances could not be administered at first. After a preliminary immunization, a few doses of arsphenamine were sufficient to make all reactions negative. The author cites one investigator who, on the basis of observations in 225 cases, reaches the conclusion that in patients who have undergone preliminary treatment with spirochetal vaccine the manifestations of early syphilis are made to disappear by chemotherapeutic substances with unequaled rapidity. If the cure of early syphilis requires the presence of considerable quantities of protective substances, this is even more important in chronic infections. The administration of spirochetal vaccines makes it possible to compensate for the deficiency of protective substances in the organism. After this immunization the organism alone is able to counteract the infection or the chemotherapeutic substances are more effective. The author shows that the vaccine therapy of syphilis has become practical since he succeeded in the mass culture and in the production of avirulent cultures of *Spirochaeta pallida*. He maintains that this immunization either alone or in combination with chemotherapy will produce a cure of the syphilitic infection and the prevention of the late sequels of syphilis, the latter aim not being satisfactorily achieved with chemotherapy alone. He shows that the spirochetal vaccine can be used also as a test substance in order to detect inactive foci in latent cases and points out that the negative Wassermann reaction is not sufficient proof of a complete cure and that in the future the negativity

of that reaction together with the lack of manifestations following vaccination with spirochetal vaccine will be required as a proof of complete cure.

Occupational Skin Diseases M. Oppenheim—p. 1359

Determination of Age by Roentgenography of Aorta.—Kreuzfuchs maintains that the increase in the diameter of the aorta from birth to the age of 70 conforms to a certain law. For the period between the ages of 20 and 70, he was able to determine with his aortico esophageal distance method that the diameter of the so called arch of the aorta is 20 mm at the age of 20 and thereafter increases each decade by 2 mm. At the age of 70 it equals 30 mm. Measurements on 200 persons revealed that this method gives correct results in 90 per cent of the cases. The author points out that his method as well as several others, although they can be employed on the living patient, are not suitable for postmortem examinations. For this reason he devised a method that permits a mathematically exact measurement of the aorta. He explains his formula on a diagram and gives an example of the computation. He shows that it is not only more simple but also more exact than his other method and that it can be used by anatomists and in legal medicine.

Abderhalden's Incretory Reaction in Hyperthyroidism—After pointing out that Abderhalden's incretory reaction has been entirely rejected by some and has been accepted by others only with considerable reservations, Schacherl relates the observations he made with this test in patients with hyperthyroidism. He concedes that different examiners frequently obtain different results and that the Abderhalden test involves sources of error. Nevertheless, he thinks that the errors can be reduced to a minimum and that the results of the test will eventually be more valuable than the determination of the basal metabolism, emphasizing that the latter has been overestimated. He points out that the physical aspects of patients with endocrine disturbances are important, since they often give indications of the type of the disturbances. In view of the fact that the Abderhalden incretory reaction indicates the existence of a disorder in the examined gland but does not reveal whether the disturbance is a hyperfunction or a hypofunction, it seems desirable to determine the type of the disorder by clinical observation. The physical aspects of incretory disturbances are especially noticeable in female patients, so that the outcome of Abderhalden's incretory test can frequently be estimated in advance. Nevertheless, the reaction complements the clinical observations considerably. The results of the reaction are recorded in a table. From these results it is evident that the disturbances which are considered of a hyperthyroid nature, are really polyglandular, with a predominance of the symptoms known as hyperthyroidism. The involvement of the various endocrine organs differs in the individual cases. Especially great is the involvement of the thymus, the gonads and the anterior hypophysis. Moreover, the clinical picture indicates an involvement of the mammary glands. In discussing the therapeutic significance of the Abderhalden incretory reaction the author shows that, in cases in which neither the thyroid nor the thymus was decomposed in the reaction, thyroid should be administered only when gonadal and anterior hypophyseal hormones are likewise required. Without this combination, the administration of thyroid should be dispensed with and only thymus should be given. However, the simultaneous administration of thyroid and thymus is never indicated. In the conclusion the author points out that Abderhalden's opinion, namely, that the decomposed organ should be compensated by its hormone, would have proved erroneous in the cases here investigated, and he stresses that the clinical use of the reaction is possible without the exact knowledge of the chemical processes that are involved.

Operation for Treatment of Cardiospasm—According to Lotheissen, most cases of so-called cardiospasm yield to non-surgical dilation, for among about 120 cases he found only two in which more radical interventions became necessary. In one of these cases he did the cardioplasty according to von Hacker and obtained good results. The second patient, a woman aged 52 had a dilatation of the esophagus and a severe cicatricial stenosis (probably the result of ulcerations). It was decided that the stenosis had to be excluded and that a new connection with the stomach had to be formed. After mentioning the shortcomings of the methods usually employed in such cases the author describes a new technic that he employed. The abdominal cavity was opened in the midline. Following division of the peritoneum at the diaphragm, the esophagus could be readily detached and drawn down for about 8 cm. It was then again attached to the diaphragmatic cleft with button sutures. After that it was turned so that the posterior wall could be seen. A fold of the fundus portion of the stomach was lifted and attached to the dilated portion of the esophagus, above the stenosed part, by means of two rows of button sutures. Then the esophagus was again turned back so that the anterior wall was exposed, and an elastic Doyen clamp was put on it directly anterior to the diaphragm. The ectasia had been well irrigated but in order to make sure that there could be no escape of contents the surroundings were well covered with compresses. Then the entire constricted portion (4 cm. in length) was incised down to the lumen and the mucous membrane was immediately attached all around to the external wall by means of button sutures—that is, a sort of cardiotomy was made but intentionally also through the mucous membrane. Then followed the intussusception of the constricted portion into the stomach and the attachment of an anterior fold, which on both sides was joined to the posterior fold with a double suture, to the dilated esophagus. By this the cut portion was completely buried. In order not to impair the sutures and yet to insure proper nutrition of the greatly weakened and emaciated patient, a gastric fistula was made. The author points out that since the disorder is always designated as cardiospasm even if the stenosis is at the diaphragm, his operation can be designated as cardiodysia (intussusception of the cardia). He thinks that cardiodysia is advisable especially for cicatricial stenoses. The covering with folds greatly reduces the danger of infection. Considerable dilatation of the esophagus is of course a prerequisite for this intervention.

Acute Appendicitis in the Aged—Korganov and Krapivina state that between 1928 and 1933, 1670 cases of acute appendicitis were treated at the Hospital Semashko in Moscow. Of these, 1638 or 98.1 per cent comprised patients ranging in age between 10 and 50 while thirty-two or 1.9 per cent were past 50. The authors summarize their study of the thirty-two cases as follows: 1 The peculiarities of the clinical course of acute appendicitis in old people conditioned by the weak reaction of the organism. Persons with generalized arteriosclerosis react poorly or not at all to local inflammatory manifestations. Systemic reaction as expressed by temperature and pulse may be absent until the development of peritonitis. 2 The atypical picture of acute appendicitis of the aged is responsible for errors in diagnosis, late recognition and a high incidence of complications. 3 Operation should be performed in

all cases of acute appendicitis in the aged as soon as the diagnosis is established. Expectant treatment is permissible in the case of abscess. 4 Because of alterations in the cardiovascular and respiratory systems of the aged, the use of general narcosis should be reduced to a minimum. 5 The authors advise the removal of the appendix except when the presence of an abscess complicates the procedure. 6 The incision is to be closed without drainage except in the cases in which the focus of infection cannot be removed or in the presence of parenchymatous oozing from the bed of the removed appendix. 7 The postoperative treatment calls for especial attention to the status of the cardiovascular, the respiratory and the intestinal tracts. 8 Mortality in the cases in which operation was performed in the early stage is not high (about 0.5 per cent), in the late and the complicated cases it reaches from 30 to 50 per cent.

*Skin Reaction to Streptococcus Toxins in Rheumatic Disease A V Kaminskaya and I T Teplov—p. 1363

Cardiovascular Disease—Chernorutskiy and Ganskay analyzed 935 cases of cardiovascular disease with special attention to distribution according to constitutional types. There were 501 male and 434 female patients. Distribution according to age was as follows: up to the age of 20 years 5.2 per cent, between 20 and 30 years 24.2 per cent, between 31 and 40 years 20.2 per cent, from 41 to 50 years 20.8 per cent, and over 51 years 29.6 per cent. Rheumatic lesions such as endocarditis and valvular disease gave the highest incidence in their series, 46.7 per cent. The next in frequency was the arteriosclerotic type with an incidence of 34.85 per cent, while syphilitic disease of the vascular system gave an incidence of 9.8 per cent. These relationships varied with the age, sex and constitutional type. The rheumatic form was more frequent in the young, the female and the asthenic type, while the arteriosclerotic and syphilitic forms predominated in the adult, the male and the hypersthenic constitution. Distribution of pathologic types in the hypersthenic patients was as follows: arteriosclerotic in 61.5 per cent, syphilitic aortitis in 11.5 per cent, rheumatic in 23 per cent and miscellaneous in 4 per cent. The normasthenic type gave an incidence of rheumatic lesion in 48.25 per cent, arteriosclerotic in 31.25 per cent, syphilitic in 10.5 per cent and miscellaneous in 10 per cent. The asthenic group showed the greatest tendency to rheumatic heart disease, 74.1 per cent and the least tendency to arteriosclerotic 14.3 per cent. Syphilitic aortitis occurred in 3.6 per cent, miscellaneous in 8 per cent. It is evident from these figures that the hypersthenic patients are four times as prone to the arteriosclerotic and three times to the syphilitic type as the asthenic patients while the incidence of the rheumatic forms is only one-third that occurring in the asthenic type.

Skin Reaction to Streptococcus Toxins in Rheumatic Disease—Kaminskaya and Teplov report 62 per cent of positive reactions to intradermal injections of Dick's streptococcus toxin in cases of acute rheumatic infection with joint involvement. The response in nonrheumatic or nonallergic diseases was positive in 20 per cent. There were four positive reactions in a group of twelve cases of a pure cardiac form of rheumatism without joint involvement. The reaction was negative in all of ten cases of endocarditis septica lenta. The positive reaction to Dick's toxin in acute rheumatic disease may persist as such for three or four months. Salicylate therapy leads to earlier disappearance or to diminution of the intensity of the reaction. Simultaneous injection of the streptococcal endotoxin (nucleo-protein) in the positive cases gave a positive reaction in 46 per cent, while injection of the exotoxin component of Dick's toxin gave a positive reaction in 16 per cent only. The authors conclude that skin reaction to Dick's toxin because of its inconstancy cannot serve as an index of rheumatic infection. A certain amount of scientific and practical interest attaches to it however, because it is observed more frequently in rheumatic than in nonrheumatic diseases and because it displays a certain dependence on the course of the disease.

*Otto's Disease and Other Forms of Protrusion of Acetabulum (Primary Juvenile Osteo-Asthenic Protrusion and Secondary Protrusions) K Overgaard—p 1001

Two Cases of Rupture of Uterus (One with Patient Moribund on Admission the Other with Recovery) J Henriksen—p 1025

Protrusion of Acetabulum—Overgaard says that the changes in the joints in Otto's disease agree with those in ordinary arthritis deformans except that in protrusion there is a forward arching of the acetabulum with a deep seat of the head of the femur and in arthritis deformans a flattening or a "wan-dering" of the joint surface laterally and upward. The deformity usually appears bilaterally, although the development of the two sides may differ somewhat. In the unilateral cases the contralateral acetabulum is generally deeper than normal. To the tabulation from the literature of the thirty-five cases that surely or most probably belong to this group are added nine personal cases, bringing the total up to forty-four or, with the addition of the six possible cases from the literature and one personal possible case, to fifty-one. Of these, thirty-one (or thirty-four) were in women and thirteen (or seventeen) in men. In men the disorder usually appears in the fourth decade of life, in women, in the fifth or sixth decade. The etiology is uncertain in all cases. The disturbance appears as a rule without demonstrable connection with other pathologic conditions. The possibility that a congenital skeletal variation plays a part in the development cannot be rejected, but the disorder cannot be regarded as merely an anatomic variation, since it occurs only in exceptional cases in younger persons. In three cases from the literature and in one personal case the disease appeared in young women, in three about the time of puberty. Because of signs of weakness in the bones, possibly due to endocrine disturbances or late rachitis and absence of arthritic changes, these cases are thought to be of other nature than Otto's disease, later development of an arthritis deformans might give rise to a picture resembling Otto's disease. This osteo asthenic juvenile protrusion occurring predominately or exclusively in young women presents an obstacle in delivery. In the differential diagnosis between a primary osteo-arthritic protrusion (Otto's disease) and a secondary protrusion due to traumatic injury, double protrusion, possibly unilateral protrusion but with a deep acetabulum on the other side marked arthritic processes with considerable sclerosis and appearance at a more advanced age point to Otto's disease. Certain trauma, more irregular protrusion and unilateral appearance with the other acetabulum natural, not particularly deep point to secondary traumatic protrusion. In infectious secondary protrusion the history and the clinical observations most often differ strongly from the picture in Otto's disease.

*Some Cases of Lead Poisoning C Lind—p 1043

Ambulant Treatment of Adipositas C C Stochholm Borresen and E Worsaae—p 1049

Lead Poisoning—Lind reports two cases of acute intoxication after intake of fourteen teaspoonfuls of lead oxide during the course of six weeks and of one teaspoonful respectively, and four cases of occupational lead poisoning after exposure to the effect of lead for six months, four months and five months, respectively. He says that the first two cases, in each of which the characteristic changes in the red blood picture were marked, illustrate the difference in tolerance of lead, the patient who had taken only one teaspoonful being more gravely affected. In one of the five cases with lead colic there was colic-like pain, in the other four the abdominal pain was constant. The lead line appeared in five, the sixth patient was toothless. The author emphasizes that anemia in occupational lead poisoning is a constant and early symptom. A slight increase in the number of reticulocytes and the appearance of basophil punctate erythrocytes in abnormal number go hand in hand in lead poisoning, being regeneration symptoms. The number of reticulocytes and basophil punctate erythrocytes is on the whole proportional to the degree of anemia. The effects of the blood poisoning have not been overcome until the anemia disappears,

the reticulocytes return to normal and the basophil punctate erythrocytes disappear or decrease, resumption of dangerous occupations with lead should not be permissible until this time. Examination of the white blood picture showed no characteristic changes. Lind says that his sixth case of anemia, without signs of active blood regeneration, is one of the rare exceptions to the rule.

*Hyperazotemia in Massive Intra Intestinal Hemorrhage. T Christiansen—p 1057

*Hyperazotemia in Acute Gastric Hemorrhage J Clausen—p 1062.

Hyperazotemia in Massive Intra-Intestinal Hemorrhage—Christiansen says that hyperazotemia occurs in grave cases of intra-intestinal hemorrhage and is a more or less marked symptom in almost all massive hemorrhages, whether due to cancer, ulcer, esophageal varices or the like. It may develop without vomiting or frequent intestinal evacuations. It may appear even if the sodium chloride elimination in the urine continues and may disappear spontaneously without salt water infusions, and it can recur repeatedly. The anemia as such is not the causal factor, because azotemia is not found in anemias in general. In intra-intestinal hemorrhages the hyperazotemia may aid in the prognosis, slight or transient rise in the blood urea indicating a good prognosis and high blood urea values, possibly with progressive rise, being an unfavorable prognostic sign, especially if the condition is complicated with symptoms of lowered turgor and achlorhydria. In such cases an attempt should be made to reduce the blood urea to normal values by the administration of physiologic solution of sodium chloride.

Hyperazotemia in Acute Gastric Hemorrhage—Clausen states that after massive gastric hemorrhages hyperazotemia appears in the course of from six to twenty-four hours and on cessation of the bleeding disappears in a few days. His studies indicate that the main cause of hyperazotemia lies in increased urea production by the organism (resorption of blood) in combination with an impaired renal function due to the effect on the general condition, no impairment of the renal function on an organic basis can be established. That a toxic effect on the organism may contribute to increased production of urea cannot be excluded. Bacterial decomposition of the blood in the intestinal canal seems not to play a noteworthy part. Increase in the urea is believed not to depend on demineralization of the organism. Three cases are cited.

*Investigations on Azotemia After Hematemesis and Melena G Alsted.—p 1069

Viscerocutaneous and Cutovisceral Reflexes in Abdomen H I Bing and E S Tobiassen—p 1076

Investigations on Fingerprint as Constitutional Mark in Mental Diseases Ctd N B Møller—p 1085

Azotemia After Hematemesis and Melena—Alsted reports eighteen cases in which treatment was carried out from March to June 1935, an abundant diet (Meulengracht) was used in fifteen and an ulcer diet in three. In fifteen cases the bleeding was caused by gastric or duodenal ulcers and in one by an esophageal varix, and in two esophageal varices were suspected. The blood urea values were abnormally high in nine cases more than 50 mg per hundred cubic centimeters and in five between 40 and 50 mg. In fifteen cases an average increase of urea in the blood to 52 mg per hundred cubic centimeters was found the day after confirmation of the hemorrhage. This azotemia diminished noticeably during the following days was then maintained for three or four weeks, and finally fell to the average normal value of 28 mg per hundred cubic centimeters (the McKays). No relation was seen between the azotemia and the degree of anemia, and the azotemia seemed to be independent of the different methods of treatment. The author is inclined to believe that even in the milder forms of hematemesis and melena some relation exists between the renal function and the degree of azotemia. The fall in blood pressure during every hemorrhage from ulcer causes impairment of the renal function for a shorter or longer time and is thus a contributing cause for the azotemia. Other conditions also, particularly dehydration, are believed to play a part in the genesis of the azotemia.
